The *Berliner Klinische Wochenschrift*, nos. 42 and 43, for 1873, contains a paper on this subject by Dr. Wilhelm Sander, of the Berlin (City) Lunatic Asylum, originally read before the Medico-Psychological Association of that capital. As ten columns or more of our contemporary are filled with this paper, we can only give the principal conclusions arrived at by the author. He remarks that some medical men think no disease so well defined, or so striking in its features as epilepsy, but it seems to him that these are just the men who know least about it. The text-book and lecture-room characters of the epileptic fit are by no means essential characters of the disease, for the attacks may really recur in very varied and yet equivalent forms. The time between the attacks is as essential an element of our prognosis, as the kind of attack itself.

The first point on which he strongly insists, is that there is no uniformity between one epileptic fit and another: the symptoms are often very varied, and any practical man knows that the text-book descriptions are for the most part abstractions from many attacks—not faithful accounts of any one paroxysm. We can scarcely be too cautious in hesitating to pronounce any given attack to be a feigned one, merely because such and such symptoms do not resemble the pictures of the lecture-room. However characteristic certain features may be when present—such as the sudden cry, sudden pallor of the face, and its later cyanotic coloration, the tonic stretching which precedes the convulsions, the turning of the head or trunk to one or other side, the coma, and so forth—yet the absence of any one of these just as little invalidates the true epileptic character of the fit. Even some of the symptoms which at first make one believe the fit to be feigned, may be genuine. The disorder is essentially Protean.

In general terms, one may say that the sudden occurrence, and the automatic course of the whole phenomena, constitute the characteristic features of an epileptic seizure. It may indeed be possible (as Calmeil's story shows) to simulate epilepsy; but it is extremely difficult, and not easily carried through.

This varied character of true epilepsy is still more true of the less known because fugitive and slighter attacks of *le petit mal*. Various muscular movements accompany these slight attacks. If the slight movement be one of chewing or swallowing, the attack is slight. If the movements be more complex, and look like voluntary ones, the attack is more severe. Sudden micturition, or disturbance of the genital organs in these attacks of momentary and epileptic unconsciousness, is not uncommon, and often gives rise to accusations of indecency. Sometimes the patient continues what he was doing when attacked, like the violinist of whom Maudsley speaks. Other attacks resemble syncope, and essentially they are probably the same—but not for medico-legal purposes. Sometimes we may form our opinion as to the true nature of the so-called fainting fit, from the frequency of the attacks, from their duration, and from the occasions which induce them. It is to be noted that in the great majority of these cases consciousness is entirely lost, although it may be only for a moment. But there are cases, which in all other features bear the stamp of epilepsy, in which consciousness is never lost.

A study of numerous cases is especially necessary in a forensic point of view, because we are often asked to form an opinion, not on seizures seen by ourselves, but on the history of the case, and the reports of others—often of non-professional persons. If in the case of a prisoner we simply ask about 'fits,' we shall often come to a wrong conclusion. Sander strongly reprobates such questions as those of which Chorinsky speaks, in which a presiding judge asked a prison-warder if a criminal had had an *epileptic* fit. It was not possible for the man to do other than guess at his answer. When mental disease is well marked, and the epilepsy slight, the latter is of little forensic importance, except as impressing its mark on the cerebral disorder. When, however, the mental disturbance is less evident, the association of epilepsy may serve to confirm the mental unsoundness, and places equivocal symptoms in a better light. When the fits are very numerous, it is common to say that the epilepsy is the *cause* of the insanity. Of course both are symptoms of the common disease which underlies them; and are mutually equivalent. Yet, doubtless, the fits themselves are prejudicial. The school-dogma that epilepsy may, but need not necessarily, have mental unsoundness as its sequel, may be true to a certain extent, but the answer would probably take a different form if both the epilepsy and the mental disturbance were regarded as collateral symptoms of a brain lesion of serious nature. The psychical characters of epileptics are well known to be characterised by mental weakness which may range from perfect imbecility to those slighter degrees of impaired intellect, which can only be recognised by close and careful observation, and then perhaps with difficulty. The persons who give us difficulty, in a forensic point of view, are those whose mental weakness is but slight, who conform themselves in most things to the ordinary customs of society, and whose peculiarities are not obvious except to their intimates. But it may help us to

remember that, however slight the intellectual failure, epileptics nearly always exhibit abnormalities of feeling. Their irritability is proverbial, and it leads them to abnormal actions, and reprisals against real or fancied encroachments. Hot temper, rash anger, and, when it comes to action, brutal want of reflection, characterise epileptics under all circumstances of life, whether trifles or more weighty matters are at stake. Besides intense irritability, they often manifest a blunting of the finer feelings, which leads to an almost total disregard of the ordinary feelings of decency and propriety. Epileptics are not bound by the ties of relationship, friendship, and love, like other people. Most of them are egotistic to the last degree. In many of them, particularly females, there is, along with mental weakness, a peculiar childish, timid, and clinging demeanour, which may afterwards become erotic. This is deceptive to the uninitiated, and often conceals unreasoning hate. Epileptics can manage some occupations very well. But only the minority really succeed in life: the great majority suffer shipwreck, if not at school, in the factory or in the counting-house, etc. Epileptics are also prone to all sorts of crooked dealings and perverted activity, and display but little power of resistance against temptations of any kind.

Are any epileptics perfectly sane? History points to Cæsar, Mahomet, Napoleon, and other great men. But of these personages we know little as regards their true and inner life. History knows only a part of a man's personality. Let us come to modern times—to the experience of private practice, of prisons and public institutions—and it may be freely admitted that, when the epileptic seizures are far apart, intellect is usually but slightly affected, or seems wholly intact. It may fully satisfy both business claims and social requirements; the individuals may even attain a certain cleverness in their chosen walk. But closer acquaintance reveals to us the hidden sorrows of the family, the self-tormenting, hypochondriac ideas of the patient, his shifting unfounded opinions, his irritability and inability to deal loyally in any circumstances whatsoever, and similar mental characteristics, which stand in close relationship to this neurosis. If to this picture we add the history of previous epileptic seizures, and the probability of future ones, it is clear that we cannot look on the actions of such a man as we would on those of one perfectly sound. Whether such an one be really responsible for his actions or no, may be open to debate in a court of law; and, indeed, no general answer can be given, so much must depend upon the nature of the crime [*That*] and the individuality of the perpetrator, as well as upon his surroundings. Dr. Sander says that we are clearly justified in asserting that we ought to make great allowances for epileptics, especially in judging of their actions. He agrees with Von Krafft-Ebing that it would be wise and humane to make a careful medical examination of every epileptic who is accused of any crime, however venial it may be. Epileptics whose mental faculties are well developed, and who retain these and their position in society, in spite of their (not frequent) fits are, according to Sander, those whose surroundings are favourable, and have been so through infancy and childhood. Under opposite conditions, we find all defects of character and intellect intensified. The social surroundings explain most of the vagabondage, begging, and thieving of poor epileptics. Crimes of violence, and

outrages against decency, often originate in the same way. Masturbation, for example, is almost certainly a part of the disease (*i.e.* a consequence, rather than a cause) in many cases. Our gaols, workhouses, reformatories, almshouses, and all sorts of pauper institutions, contain an overwhelming number of epileptics. A careful attention to training and education (in the widest sense), and a recognition of the increased care needed by young epileptics, would vastly diminish crime of all kinds. [Here follow remarks on hallucinations and spectral and other illusions, of little novelty to the English reader.] The peculiar 'pauses,' or intervals of consciousness of epilepsy, lasting from a few minutes to a few hours, in which epileptics act as if they had no history, past or present, are of great interest and importance. In this peculiar state they act as if they had planned to do all they do, although, in reality, their actions are automatic. They often retain no consciousness of their acts—so that they cannot be brought to remember that they have done them; *e.g.* a man will buy a cap and pay for it, and then wonder why he has it in his hand. Stories of this kind may be multiplied *ad infinitum*. Cases of crime committed under such circumstances are more difficult to deal with. The doctor often sees the patient for the first time, after he has been rudely awakened from his unconsciousness by the very fact of his arrest for the crime. Under such circumstances, all the low cunning of the epileptic is now aroused, and self-interest will prompt both himself and his friends to deceive the doctor if possible. But Sander thinks a careful study of each case, and of his social surroundings, education, etc., will generally lead us in the right direction. He evidently feels more strongly than he states, that it is both cruel and unjust to punish an epileptic as we would a common criminal with full responsibility. It is the part of science, no less than of humanity, to enlighten justice. In a given case of crime, we may find in the criminal no positive sign of insanity in the ordinary sense of the word, but we may have a history of epileptic attacks, and he may present all the mental and social weaknesses, and worse, on which remarks were made above.

Sander discusses the case of the so-called 'morally insane,' in whom perhaps we have no definite history of epileptic seizures, and is evidently of opinion that, in the absence of definite motive, crimes of great atrocity and suddenness must often be attributed to masked or larval epilepsy. At the same time, he is fully alive to the fact that forensic medicine, or rather the law in consulting physic, asks for generally received opinions and admitted facts, and is very chary of admitting novel views, especially when they involve the question of the non-responsibility of criminals. His object, therefore, is rather to secure unanimity of opinion, and a careful study of the true facts of the disease, on the part of his medical brethren, than to pronounce authoritatively as a medico-legal expert. [Although Dr. Sander's paper contains little of absolute novelty, and is rather (unconsciously, perhaps) a reflex of the views of French psychological writers, particularly of Laurent and Delasiauve, it is yet so catholic in its views, and so judiciously as well as judiciously written, as to suggest that the publication of the article *in extenso* would probably be acceptable to those who are interested in psychology.

—*Rep.* W. BATHURST WOODMAN, M.D.

REICH ON THE PHYSIOLOGY OF THE SECRETION OF TEARS.*

Dr. Herzenstein (*Beiträge zur Physiologie und Therapie der Thränenorgane*, Berlin, 1868), Dr. Demtschenka (*Zur Physiologie der Thränensecretion und Thränenleitung*, Petersburg, 1871), and Dr. Wolferz, have demonstrated in a decisive manner that the secretion of tears is placed in dependence on the lacrymal nerve, and partly also on the subcutaneous malar nerve.

The two last mentioned physiologists also admit that sympathy exercises a certain influence over the production of tears. Demtschenka even affirms that the quantity of tears obtained by the irritation of the sympathetic nerve is always more considerable than the amount produced by the irritation of the lacrymal nerve. According to these writers, the fibres of secretion contained in the lacrymal labyrinth proceed from the trigeminal nerve; but as they have in their experiments neglected to direct the irritation to the peripheral extremity of the trigeminus divided in the interior of the cranium, Dr. Reich has thought it advisable to take up and modify these experiments. His method of proceeding and his results are as follows. When an animal which has undergone severe injury is experimented on, the opening of the bony case of the skull and ablation of the encephalon having brought on a considerable loss of blood, the irritation of the peripheral extremity of the trigeminus does not produce any increase in the secretion of tears.

This result may be attributed to the want of circulation in the lacrymal gland. In order to put himself beyond the reach of this source of error, Dr. Reich operates as follows. A cannula is introduced into the trachea, the right brachio-cephalic artery is tied, as well as the left vertebral artery, the cranium is opened and the brain removed; the left carotid being compressed during the whole time the operation lasts. Artificial respiration is afterwards kept up, the heart continues to beat, and circulation is effected through the gland.

Eleven experiments were made under these conditions, in ten of which there was no increase of secretion; once only the eye was slightly moistened. The irritation took effect every time on the peripheral extremity of the divided trigeminus exclusively. This evidently proves that the irritation of the peripheral extremity of the trigeminus in rabbits does not at all increase the secretion of tears.

It may be thought that the rabbit was not a very favourable subject for these experiments, since the direct irritation of the conjunctiva by tobacco, ammonia, &c., brings on but little reaction in these animals; but the case is different when another means is employed. By introducing into one of the nasal fossæ a piece of paper soaked in essential oil of mustard, a very abundant and profuse secretion from both alæ is induced.

It is easy to convince oneself that the hypersecretion of tears which arises from the side opposed to the one irritated is also quite due to a reflex action, and not to the direct action produced by the evaporated essential oil; for, on covering up the eye on that side, after having previously closed up the corresponding nostril, the same phenomenon always takes place. If experiments be made on rabbits after having

taken the precautions indicated, it can be proved that the excessive secretion of tears, so easily brought on by the irritation of the nasal mucous membrane by means of the essential oil of mustard, constantly occurs on both sides in a nearly equal manner, whether one only or both the trigemini be cut, or even if they be left intact.

This proves that the lacrymal nerve derives its physiological properties from nerve-fibres other than those of the fifth pair, a result which is by no means surprising, since the known secretory nerves of the animal economy, as well as the motor nerves, receive a centrifugal impulse. We must, therefore, seek elsewhere for the nerve-fibres conducting to the production of tears.

By dividing the great sympathetic at the neck and exciting the central extremity, Dr. Reich has established, like his predecessors, Demtschenka and Wolferz, an excessive secretion of tears. This result, however, has not been constant in all the experiments. If the superior cervical ganglion be removed, the excessive secretion persists; if the trigeminus of the same side be cut at the same time, it still persists.

These researches lead to the irresistible conclusion, that the centrifugal nerve-fibres which are employed in the innervation of the lacrymal gland are situated above the superior cervical ganglion, and perhaps in the medulla oblongata, where are situated the fibres of the origin of that sympathetic nerve which regulate the salivary secretion.

Irritation of other nerves, such as the fourth pair, which anastomose in the cranium with the trigeminus, has not given any result.

The functional relation existing between the production of tears and the contraction of certain muscles of the face in weeping, laughing, &c., has led the author of this memoir also to study the action of the facial nerve, and he has established the fact that after the section of this nerve the reflex secretion always remains the same.

FORENSIC OPHTHALMOLOGY.

ON INJURIES OF THE EYE IN THEIR MEDICO-LEGAL RELATIONS. BY PROFESSOR ARLT, OF VIENNA.*

(Continued from page 273.)

15. *Dislocation of the Crystalline Lens.* A lens entirely separated from its connections may for some time be only partially displaced, but sooner or later it undergoes a marked change of position, if this have not already taken place in the act of injury. There are also cases in which an incomplete dislocation becomes complete, under the influence of a fresh concussion of the eye.

The completely dislocated crystalline lens may retain its transparency for weeks, months, or years. It is found depressed into the vitreous body, or in the anterior chamber, or entangled in the pupillary opening of the iris.

In one case, after a blow on the left eye, I saw the lens pushed inwards and upwards, and pressed against the iris; the pupil was dilated nearly as much as by atropia, so that, with a meniscus, the fundus of the eye could be seen, though not distinctly. In this case, the dislocated lens was exceptionally immov-

* *Zur Physiologie der Thränensecretion.* By Dr. MICHAEL REICH, of St. Petersburg. (*Archiv für Ophthalmologie*, tome xix. 3e partie, p. 38.)

* *Wiener Medizinische Wochenschrift*, April 25 and May 2, 1874.

able; the globe felt hard. Fingers could only be counted at a distance of five feet; number 10 only of Jäger's test-type could be recognised, through a small opening in a dark plate. Further changes could not be found.

The lens may pass from one position into the other; it may lie alternately sometimes before, sometimes behind the iris. Beyond the impairment of vision, the disturbance may be very slight, though lasting for years; but amaurosis, obstinate inflammation of the uveal tract, and even suppurative destruction of the eye, may be produced. It has already been observed (in section 4) that, when there is a rent in the sclerotic, the lens (usually without its capsule) may pass under the conjunctiva, or may remain partially in the eye (in the neighbourhood of the laceration of the ciliary body).

16. A lens *lying in the anterior chamber* is easily recognised when transparent, by the pale yellow colour, and by the brightness of its edge. The crystalline lens does not completely fill the anterior chamber, although it presses the iris backwards. If the lens have become opaque, and have fallen into the anterior chamber at a late period—often many years—after the injury, it is generally reduced in size by fatty degeneration and by calcareous deposits on the inner surface of the capsule, has a chalk-white appearance, and is uneven, sometimes more globular, sometimes more placentaliform. It may be free and movable, or may be adherent to the cornea or to the iris.

If the lens be already opaque at the time of the injury, the patient will be sensible not only of disturbance of vision, but also of a white opacity in the pupil. The diagnosis in this case is not attended with any difficulty.

Prognosis.—A lens lying in the anterior chamber may in time become opaque and smaller, but is never absorbed. If it remain long lying at the bottom, resting against the cornea, this part of the cornea becomes gradually opaque; and this opacity is not lost even after removal of the lens. It has also been observed that the part of the cornea involved becomes destroyed by ulceration. Such lenses are often borne for many years without remarkable trouble; but in many cases they appear to give rise to persistent iridocyclitis, attended with more or less severe paroxysms of pain. There are next an increase of serous exudation in the space which the lens formerly occupied, inflammatory softening of the zone of the sclerotic corresponding to the ciliary process, and a pyriform change in the shape of the globe, while the thinned and distended sclerotic pushes the base of the cornea forwards, either in the half or all round. There may further be serous effusion in the vitreous body, increased tension of the whole bulb, and glaucoma (pressure-excitation of the optic nerve). There may be an advanced stage of calcification of the lens, without the posterior part of the eye being essentially affected. In the early period of my practice, I saw a musician so far relieved by the removal, by the flap-operation, of a nearly calcified lens, which had lain a number of years in the anterior chamber, that he could go about without a guide (he was blind in the other eye.) Cataract-glasses were of little use to him, probably in consequence of opacity of the cornea below its middle, where the cataractous lens had lain.

Treatment.—Prolapse of the crystalline lens (in its unopened capsule) indicates positively extraction from below by a curved incision. The operation

should not be delayed after any chemosis caused by the injury has passed off. The patient should be in bed in the half-sitting position, so that the lens may not sink backwards through the pupil. The operator can generally judge before commencing whether the knife should be carried before or behind the lens, or even through it. The best instrument is a slender Beer's knife. The wound should allow the lens to escape easily; if this do not take place when the incision is completed, the lens must be extracted by a Daviel's curette, or by a hook or forceps. Pressure on an eye thus affected may readily be followed by considerable injury of the vitreous body.

17. *Depression of the Crystalline Lens into the Vitreous Body* may readily be detected in some circumstances; but its recognition is difficult or even for some time impossible, when at the same time there is hæmophthalmus. If there be neither effusion of blood nor laceration nor paralysis of the iris, the iris lies somewhat deeper, at the same level throughout (in a manner approached only in myopia), and trembles violently when the vision is suddenly changed from one object to another; the pupil is small, and of a remarkably pure black. The crystalline lens, having a higher specific gravity than the vitreous body, is pushed backwards and forwards by every sudden movement of the eye. If there be no impediment on the part of the retina or in the transmission of light, the patient when lying on his back sees the crystalline lens by means of the shadow which it throws on the retina. If the head be inclined forward for some time, the lens may even resume its position behind the pupil. If the pupil be not too narrow, and the media be sufficiently transparent, the transparent lens may be easily recognised by the phenomena of reflection described in sections 13 and 14, the opaque lens by its size, form, and colour, by means of the ophthalmoscope.

Prognosis and Treatment.—If the eye have suffered no other injury, it may continue to discharge its functions for several years, though imperfectly. It may, however, probably from repeated irritation of the iris and ciliary body, pass into a state of chronic inflammation with serous exudation, and of glaucoma. The crystalline lens may pass half way into the anterior chamber, and become caught in the pupil, from which it must be removed at any cost, if it be desired to prevent the eye from being destroyed by violent inflammation. Prolapse into the anterior chamber is probably the best thing that can be desired, in order that extraction may be performed. Strong mydriasis, and gentle repeated taps on the eye while the pupil is directed downwards (the head being bent forward) may produce this condition; after which the pupil is again narrowed by the energetic use of Calabar bean. Extraction may then be attempted in the way described in section 16, but is here attended with more or less loss of vitreous humour. Discission in the vitreous body is, if not impossible, at least very difficult, and rarely less dangerous than extraction with loss of vitreous humour.

18. *Injury of the Retina by Contusion or Concussion of the Globe.*—Not only before, but also after the introduction of the ophthalmoscope into practice, it was usual, even in recent times, in cases of disturbance of vision after injury, where no changes could be detected by unaided vision or by the ophthalmoscope, to locate the lesion within the skull, to use the term *commotio retinae* in explanation of the partly

transient; partly permanent disturbance of vision, and to assume a minimum degree of disturbance of the elements of the retina or a paralysis of the vaso-motor nerves through concussion. Dr. Berlin (see section 1) pointed out the untenability of this supposition, and struck out the path of more exact observation.

We may, with more probability, assume that concussion of the retina has taken place, when the eye alone has been struck directly by a blunt instrument. This group is divided into two groups: those in which disturbance of vision, generally of a high degree and accompanied with impairment of excentric vision, is permanent, or, at least, of long duration, and those which show only a slight impairment, *i.e.* of central vision alone, which generally passes off in a few days. From repeated observation, I agree with the opinion of Geissler and Knapp, that amaurosis or a high degree of disturbance of vision after concussion of the eye very rarely occurs without changes which may be discovered by the ophthalmoscope.

As regards the explanation of the milder cases by assuming the thrusting of the elements of the tissues against each other, this is just as little tenable with regard to the retina as to the brain; and with regard to the hypothesis of paralysis of the vaso-motor powers, Berlin could not, after careful comparison of the injured with the sound eye (in man and in rabbits), discover any dilatation of the arteries or of the veins. From his observations and experiments, Berlin arrived at the conclusion, that in all cases where concussion of the eye is followed by slight disturbance of central vision or unequal impairment of excentric vision, and recovery follows in a short time, the case is merely one in which there has previously been irregular astigmatism. This assumption is partly strengthened by the constant resistance of the iris to atropia, partly by the anatomical changes found in experiments on rabbits, in the anterior part of the eye. 'If a more or less hard and blunt body had struck the eye without producing any appreciable injury of the tissues or of the external structures, we found, immediately after the injury, a moderate degree of impairment of acute central vision, or an unequal impairment of excentric vision. At the same time we found, without exception, much episcleral injection, and considerable resistance of the iris to the action of atropia. After about an hour, we saw in a certain part of the fundus of the eye a dark grey cloudy opacity, which in two cases increased by the confluence of smaller opacities and became more intense; in two cases, small hæmorrhages were observed in the neighbourhood. The opacity in four cases lay around the pupil and macula lutea, in two on the outer side of the fundus oculi, and in two cases two large distinct parts of the retina were obscured; in each of these two cases an opaque spot belonged to the anterior half of the retina, and the other to the posterior part of the globe. The opacity seemed to reach its height in a period of twenty-four to thirty-six hours; after two or three days, on an average, it could no longer be seen. It was found to have no influence on the degree of acuteness of vision, whether the opacity of the retina was found in the neighbourhood of the macula lutea or was situated excentrically, and that the disturbance of vision constantly diminished, while the opacity was still increasing or had reached the height of its development. The improvement of the acuteness of vision made

rapid progress in the first twenty-four hours, but afterwards went on more slowly. In the first hours after the injury, I have not seen perfect dilatation of the pupil, even after dropping in atropia six or eight times. This irritability of the sphincter of the iris diminishes rapidly, but, though in a moderate degree, it and the disturbance of vision continue beyond the ophthalmoscopic changes, and the restoration of sight appears to make progress as the irritability decreases. I could not ascertain that there were changes in the tension of the eye.'

In experiments on rabbits it was found, on examination with the ophthalmoscope, that, when the injury had fallen on the sclerotic, extensive opacity was found on the part of the retina corresponding with the part of the sclerotic that was struck, and also a similar opacity in a neighbouring part of the fundus oculi lying directly opposite the struck part. On anatomical examination, the important discovery was made, that the retinal opacity was only due to acute oedema, dependent on hæmorrhage between the choroid and sclerotic. 'If the blow struck the cornea, we found as a rule, besides the subchoroid hæmorrhage, limited hæmorrhages between the ciliary muscles and the anterior section of the choroid on the one hand, and the sclerotic on the other. Though not with absolute regularity, we frequently found also hæmorrhages between the pars ciliaris retinæ and the choroid, as well as limited effusions of blood in the posterior wall of the iris and in the canal of Schlenem. Thus, in our experiments, what we had to deal with was essentially rupture of the choroidal vessels.'

Subchoroid hæmorrhage, as such, may not cause disturbance of vision; and, from what has been said above, this may occur without retinal opacity. Berlin 'saw two cases of injuries of the eye by blunt articles, in which, although there was considerable disturbance of sight, no changes in the retina could be detected by the ophthalmoscope. Both cases, however, showed much injection about the cornea, and a high degree of resistance of the iris to the action of atropia; and in one there was severe iritis. . . . On the other hand, it is very probable that hæmorrhage in the immediate neighbourhood of the lens acts on the form, and in some cases also on the position of the lens, and, in conjunction with the spasmodic contraction of the sphincter iridis, produces irregular astigmatism. . . . The course and degree of the disturbance of vision agreed very well with the supposition that the changes in form and position of the lens were to be referred to the mechanical influence of small collections of blood.'

I have already stated in section 1 the reasons why I cannot agree with Berlin's opinion as to the production of rupture in the posterior circumference of the choroid. I will here only add, that rupture of the uvea in the anterior section of the globe may arise partly from contusion of the portion of the choroid lying directly beneath the affected part of sclerotic, partly from flattening of the cornea, and sudden widening of the corneo-scleral ring; while the sclero-uveal laceration removing concentrically to the edge of the cornea is to be considered a result of sudden distension of the globe in that circle, of which the laceration itself forms a portion.

(To be continued.)

CLINICAL MEDICINE.

ON VARICELLA. BY PROFESSOR HENOCK,
OF BERLIN.*

The motive for making the following communication has been afforded me by a little epidemic of varicella, which I had the opportunity of observing in the children's department in the Charité Hospital, in the summer of 1873. The first case occurred in a boy aged six and a half years, who was admitted on account of scrofula, on April 2, and on the 23rd—twenty-one days after his admission—was attacked with varicella. As there had been no case of this disease in my wards for several months, one was at first led to believe that infection had taken place before the child's admission, in which case the stage of incubation must have lasted at least three weeks. So long a duration of this stage, however, is in contradiction to nearly all observations; and I therefore preferred to assume the previous existence in the institution of an infection, the source of which was unknown. In the same inexplicable manner I have seen parotitis suddenly break out in the wards, and attack a number of children in rapid succession. Most probably, the contagion is brought from without on the visiting days.

From this child, a number of others were, by degrees, infected, partly in the same ward, partly in the adjoining ones. The combination of the exanthem with measles, which prevailed in the department at the same time, was interesting. Several authors—for instance, West—have commented on a special relation believed to exist between these two exanthematous diseases, in consequence of their rapid sequence in the same individual being observed with remarkable frequency. This circumstance was observed in our epidemic, inasmuch as five children were seized with varicella very soon after convalescence from measles. (I shall return to this subject.) I cannot accept this as evidence of a relationship between the two diseases, in favour of which West expresses himself; for the children with measles naturally lay for some time together in separate wards, and varicella breaking out in one of them would much more readily infect the adjoining patients than those in distant wards, and suffering from other diseases.

The interval between the two exanthemata was very long in one case only, viz. six and-a-half weeks. This child was taken ill with measles at the end of March, at a time, therefore, when varicella did not prevail in the institution. It had varicella on May 13. Three children (in five cases accurate observations were not made) came into the hospital on May 22, 23, and 28, with premonitory symptoms of measles, or with the eruption already developed, and were attacked with varicella on June 2, 3, and 17; thus at intervals of 11, 12, and 20 days. It cannot indeed be determined with certainty on what day infection actually took place under such circumstances—i.e. in a hospital atmosphere containing the contagium. As, however, observations in families show that the incubation-period of varicella is almost always fourteen days, both of the first two children must have been infected with the contagium of varicella during the prodromal stage of the

measles, or at least during the eruption and its efflorescence; this is an additional proof that the development of one acute exanthematous disease by no means excludes the possibility of infection by another. I take this opportunity of referring to a case of scarlatina observed in my private practice, in which, on the twelfth day after the eruption, an enormous outbreak of varicella took place over the whole body and even on the mucous membrane of the mouth. The infection must then in this case have taken place during the incubation-stage of the scarlet fever, while the boy was still attending school; as, from the time when the scarlatinal eruption appeared, he did not come into contact with any other child.

In one case only were appearances observed, which allowed the supposition of a simultaneous attack of the two diseases. A child, two years old, admitted in April with caries of the sacro-iliac articulation and whooping-cough, presented on May 13, with severe febrile symptoms, an abundant papular exanthem rapidly spreading over the body from above downwards, confluent in large spots in many places, and attended with catarrhal symptoms, which on the 18th, after the eruption had completely faded, went on to broncho-pneumonia. While this was going on, on the 16th, varicella appeared, and was fully developed on the 18th. With the simultaneous prevalence of both exanthemata in the institution at this time, and the very characteristic symptoms, I can scarcely doubt the simultaneous existence of measles and varicella in this case.

With regard to the phenomena of the disease, I observed in one case only, that of a boy five years old, a prodromal exanthema, in the form of a diffuse erythema preceding the eruption by several hours, and accompanying it on the first day. In a second case, the eruption was preceded for one day by conjunctivitis, and in a third by slight angina; affections which I regard rather as accidental than as connected with the varicella. Headache, vomiting, and increased heat, were showed in two cases shortly before the eruption appeared. I paid special attention to the temperature, as, in spite of many well established opposing observations, the opinion still prevails with many physicians, that chicken-pox is a disease free from fever, in which the children can be left to themselves without fear. Daily thermometrical observations in twelve cases showed that during the eruption, and even on the second day of the disease, there is a febrile state, which, however, is very mild in most cases. On the first and second days, the temperature varied between 100° and 101·8° Fahr.; being higher in the evening than in the morning. In two cases only it fell to 100° and 99·6° Fahr. on the morning of the second day, and again rose in the evening to 101·3° and 102·6° Fahr. The eruption generally came to an end on the second day; after-crops might appear without increase of temperature. In one case the temperature sank on the third morning to 100°, and in the evening, in spite of further eruption, to 98·6° Fahr. In general, the fever thus appeared to reach its end on the second day. I have never observed varicella to run its course absolutely free from fever; for no conclusion can be drawn from the observations made in private practice, in which, on account of the slightness of the malady, the thermometer was not used. In a boy aged three-and-a-half years, who first presented the eruption of varicella on May 13, the temperature was only 99·5°, and in the evening 99·6°

* A Paper read before the Medical Society of Berlin. (*Berliner Klinische Wochenschrift*, May 4, 1874.)

Fahr. As, however, the vesicles were already partially dried, I have no doubt that the eruption was already two or three days old, but that it had been overlooked on account of the absence of constitutional symptoms (the child was convalescent from measles).

In a comparatively small number of cases only did the fever attain a high degree and a long duration. In one child, the thermometer on the evening before the eruption showed a temperature of $101^{\circ}5'$, on the evening of the second day $102^{\circ}2'$, and on the third day 102° . In another case, where the diffuse erythema of the skin preceded and accompanied, the fever set in with a temperature of $104^{\circ}9'$; on the second evening, however, the temperature was only $100^{\circ}9'$, and on the third day the fever had completely disappeared. In one case only the fever was quite unusually high and of long duration. The patient was a boy aged six, in whom, during the efflorescence stage of measles, tracheotomy was performed with success on account of croup. Convalescence was nearly complete, and the wound was almost healed, when he was attacked with the varicella then prevalent in the hospital. The course of the fever was as follows.

| | Morning. | Evening. |
|---------------------------------------|------------------|-------------------------|
| Evening before the eruption | — | $101^{\circ}48^{\circ}$ |
| First day | $102^{\circ}2'$ | $104^{\circ}45'$ |
| Second day | $101^{\circ}48'$ | $104^{\circ}9'$ |
| Third day | $102^{\circ}9'$ | $105^{\circ}8'$ |
| Fourth day | $102^{\circ}2'$ | $102^{\circ}75'$ |

On the fifth day, he was free from fever. Thus in this case, after a premonitory stage, the fever lasted four days, indicating degrees of temperature which are otherwise only present in highly developed infectious diseases, in fibrinous pneumonia, &c. I believe that two facts will aid us in explaining this unusual circumstance.

1. This boy was specially predisposed to high fever. When, some weeks later, he had an unimportant rash, caused by indigestion, he had for three days an evening temperature of 104° Fahr. and more.

2. The remarkable extent of the eruption of varicella might have an influence on the height of the fever. The abnormal increases of temperature in this disease are, as I have convinced myself by many observations in private practice, always connected with a widely spread and thick eruption, the vesicles of which in great part undergo a purulent change on the second or third day. It is these cases which keep up the still unsettled contest as to the identity or non-identity of varicella and variola. Let one only read the article by Kassowitz in the *Fahrbuch für Kinderheilkunde*, 1873, and the reports of the recent discussions in Vienna on this subject (*ibid.*), and one will be astonished at what I may almost call the juristic sophistry, with which the advocates of the unity doctrine have contended for their views. In my opinion, every unprejudiced observer must range himself on the side of the dualists. It is not singularities that settle the matter here, not the circumstance that individual vesicles of varicella have a central depression, and that their contents may become purulent. Taken altogether, the differences are always so marked, that, to me, a perfect separation of varicella from the variola group seems indispensable. Our little epidemic completely supported this opinion. We had here before us in the same hospital a whole series of cases, which manifestly arose from mutual infection. I ask the unionists, why did the disease always begin with clear vesicles

proceeding from a red spot? Why did all the cases, with the exception of one distinguished by a fever lasting four days, and a very diffuse and partly purulent eruption, show the well known characters of varicella? And does not this one case correspond completely with those irregularities which we observe in other acute exanthemata? Take, for instance, the exceptions of scarlatina, which in almost all cases commences as a diffuse erythema, but, under very severe cutaneous inflammation, is often enough mixed with papules or with vesicles, which may even have puriform contents. In spite of this, the disease is still scarlet fever. Just in the same way I regard these exceptional cases of chicken-pox. Two cases came under my care in private practice, in circumstances which to me were decisive. Two sisters, both vaccinated, were ill with varicella at the same time; one had the disease in as severe a form as in the boy whose case I have related above, having strong fever, with severe headache, and the body thickly covered with vesicles, some of which underwent purulent change; the other had no constitutional symptoms of importance, and only a very few clear watery vesicles. In another family, a child three years old, who had been successfully vaccinated, was so severely ill that I should have been misled, had I not seen the eruption of clear vesicles. In a fortnight, the elder brother had a very mild attack of vesicular chicken-pox. The extension of the disease among the grown members of the family, or of the household, such as often occurs in variola, was not observed in one of these cases; nor was a single member of the staff of attendants attacked during the epidemic in the Charité.

With this agrees the circumstance which I have often observed, of varicella attacking the mucous membrane of the mouth and inner surface of the lips. I saw here the same clear vesicles as on the skin, but always very scanty; nor have I seen the white conical elevations, as in the stage of the outbreak of variola. Now and then, single rather opaque vesicles, with surrounding congestion, on the conjunctiva of the eye, came under my notice. After-crops of the eruption, appearing in very irregular succession, are rather usual; so that not unfrequently the back and the lower limbs are first affected, and then the face for the first time on the third day; or fresh clear vesicles appear among those which have already dried. I cannot agree with the opinion of Thomas (*Archiv für Dermatologie*, 1869) when he contradicts the occurrence of such after-crops. Through scratching by the children, ecchymatous pustules, circumscribed erythema, and small ulcerations are often produced, and obscure the eruption. The disposition of parts of the skin that are irritated or pressed on to acute exanthemata, specially observed by Hebra, is met with also in varicella. Thus, in a child which lay constantly on its left side, the eruption was here much more marked than on the right side; in a boy with a congestive abscess as large as a child's head in the flexure of the left hip-joint, the distended skin over the abscess was the seat of a thick eruption, which appeared only sparsely over the rest of the body. Chronic skin-diseases have little influence on the eruption. Some years ago I saw two children with congenital ichthyosis, in whom varicella was regularly developed. Finally, I would call attention to a Moorish boy in the hospital, whose dark brown skin, after the eruption of varicella, appeared as if scattered over with transparent pearls.

ANATOMY AND PHYSIOLOGY.

FOSTER ON THE IMPORTANCE OF SALTS IN FOOD.—Foster (*Zeitschrift für Biologie*, vol. ix. p. 297) has made some interesting experiments on dogs and pigeons, which show that animals die when inorganic salts are altogether absent from their food, although the other nutritive constituents may be abundant. In all animals, a condition of muscular weakness and tremor occurred, which is best designated by the term general exhaustion. The weakness of individual groups of muscles in the dog, and especially those of the posterior extremities, from the second week of the experiment onwards, gradually assumed a paralytic character, such as is observed when the function of the spinal chord is weakened. The activity of the cerebrum was also impaired, as was evident from the increasing bluntness of the senses and the apathy of the animal. Later on, symptoms of increased excitability often appeared. Thus, when the author quickly entered the room where one of the pigeons had ventured upon the cross bar of the cage, it fell suddenly upon the floor of the cage, and there remained crouched in the ordinary stupid position with its eyes closed and its head drawn in. Dogs always cowered at once, as if terrified, whenever any quick motion was made towards them even from a distance. On one occasion, one of them had an attack of madness, springing at the keeper and barking, but crouching down, trembling and growling, when it heard his voice. On being taken out it ran straight forward, and knocked its head violently against a wall in its way. There was tonic contraction of the muscles of the jaw and neck. After the animal has been deprived of salts for some time, the juices of the intestinal canal either lose their digestive power or are not secreted in proper quantity, and nutrition is thus interfered with. Death takes place, however, from the alterations in the nervous system, before there has been time for it to occur from inanition. The quantity of salts necessary to life is smaller than is generally supposed, but the exact amount required is still to be determined.

T. LAUDER BRUNTON, M.D.

GIERKE AND P. ROKITANSKY ON THE RESPIRATORY CENTRE.—Gierke (Pflüger's *Archiv*, vol. viii. p. 583-600) locates the respiratory centre in a longitudinal bundle of fine nerve-fibres, lying on each side of the middle line in the medulla oblongata. It has previously been described as belonging to the origin of the vagus and glossopharyngeal nerves. It is a continuation of bundles, which, higher up in the medulla, pass out transversely from the nuclei of the vagus and hypoglossal nerves, then proceed longitudinally downwards, and lose themselves in the reticular nervous tissue between the anterior and posterior horns. This respiratory centre does not consist of a distinct group of cells. The author regards respiration as a reflex act, the afferent nerves being the trigeminus and vagus, and the efferent nerves the phrenic, intercostal, and other nerves.

Prokop Rokitansky (Stricker's *Medicinische Jahrbücher*, 1874, p. 30-41) considers that the respiratory centre is not confined to the medulla, but extends to the cord; for he finds that respiratory movements occur in rabbits poisoned by strychnia, although the medulla has been separated from the spinal cord. Rabbits die from imperfect respiration when the medulla oblongata is cut through at the

posterior border of the pons Varolii. When respiration has been arrested by dividing the medulla at this point, it begins again if strychnia be injected. [The action of strychnia in exciting the spinal portion of the respiratory centre is similar to its action on the vasomotor centre as described by Schlesinger; *vide* LONDON MEDICAL RECORD, vol. ii. p. 36.—*Rep.*] T. LAUDER BRUNTON, M.D.

JUVENTIN ON UREA IN VOMIT.—Dr. Juventin (thesis quoted in *Gazette Médicale de Paris*, April 25) informs us of the interesting fact that all vomited matter contains a certain proportion of urea. In fact, according to M. Juventin, 'the excretion of urea by the mucous membrane of the stomach is normal, and goes on in an amount proportionate to that contained in the aqueous portion of the blood.' The blood in the normal state contains 0.16 centigrammes of urea to the litre, according to Picard's analyses.

The quantities of urea contained in the vomited matters have been determined by the process of M. Bouchard.

FOUILLOUX ON VARIATIONS IN UREA.—An essay by Dr. Fouilloux on the variations of urea, contains besides some original researches made by himself, the sum of our knowledge concerning the quantitative modifications of urea daily excreted by the urine. The author describes the old and new methods for determining the amount of the urea, the latter being, as we know, founded on the employment either of hypobromite of soda, as practised by Yorn, Esbach, Regnard, and Hufner; or of Millon's re-agent, as practised by Gréhaut, Bouchard, and Quinquaud. The second chapter of the work is devoted to the physiological variations of urea; the third to the variations due to therapeutic influences.

The action of oxygen, of the chlorides, of diuretics, baths, coffee, digitalis, alcohol, &c., is successively passed in review. Finally, in the fourth chapter, which is the most fully developed of the series and contains the results of Dr. Fouilloux's own researches, he examined the pathological variations of urea.

The author's analyses relating to hepatic affections are specially worthy of consideration.

RIEGEL ON THE INFLUENCE OF ALCOHOL ON THE TEMPERATURE OF THE HUMAN BODY.—We are indebted to the *Berliner Klinische Wochenschrift* for the following abstract of the original paper in the *Deutsches Archiv für Klinische Medizin*, vol. xii. parts 1 and 2.

The ordinary sources of fallacy in experiments on the action of alcohol were, as far as possible, guarded against by Riegel, as follows. 1. Not content with prefixing one typical or theoretical curve of normal temperatures to the whole set of experiments, he constructed and prefixed to each experiment a normal temperature curve of the subject of such experiment, drawn from actual observation of each individual. 2. The measurements of temperature were simultaneously made in the axilla and in the rectum; it could not, therefore, be objected that the slight depressions were due to the thermometer shifting in the axilla, &c.

On the whole, his experiments confirm those of Binz and Bouvier [we may also add, of Dr. Parkes, Dogiel, Sydney Ringer, and the Reporter]. The general results of the experiments are the following.

1. Alcohol depresses the temperature, not only in febrile diseases, such as typhus, erysipelas, and

pneumonia, but in a febrile condition also; this depression generally amounts to only a few tenths of a degree (centigrade), and lasts for a short time only. Very rarely there is an equally great rise of temperature.

2. In those recovering from severe illness, the downfall is somewhat less, or, more often, altogether absent. This is also the case in those habituated to alcohol.

3. The larger the dose, the greater the downfall of temperature.

4. Riegel concludes that, although alcohol scarcely deserves the reputation given to it in England, as a decided depressor of temperature, yet, on the other hand, it never essentially raises the temperature—the constant dread of continental practitioners—and it is decidedly one of those things which diminish bodily waste, like tea and coffee.

W. BATHURST WOODMAN, M.D.

DUJARDIN ON MEDICAL THERMOGRAPHY.—Dr. Dujardin has published (*Gazette Médicale de Paris*, April 20) a description of a thermograph of his own invention, consisting of, 1. A thermo-electric pile; 2. A self-registering galvanometer. The metallic elements are formed of iron and German silver; one of the points of union of which is maintained at a constant temperature, by a very ingenious arrangement. The needle of the galvanometer terminates in a delicate prolongation made of aluminium, very carefully balanced, the indicating extremity of which moves above a thin plate of glass. A layer of opaque varnish, laid on the surface of the glass, covers it entirely, with the exception of a band about a millimètre wide, which represents the chord of the arc described by the movement of the needle from one end of its chord to the other; a line which corresponds to about thirty degrees on each side of the zero of the galvanometer. On this transparent portion a photographic paper is unrolled, and is drawn with a slow and continuous movement by watchwork, in the direction of the length of the needle. Its luminous rays, starting from a lamp, and reflected by a mirror placed at a proper inclination, strike the photographic paper vertically, and produce an impression on it, except at the place where the needle projects its shadow. Thus, a continuous straight or sinuous line is obtained, according to the fixity or mobility of the needle.

Within the limits of the physiological temperatures, the intensity of the currents are in proportion to the differences in temperature of the two points of union. But, the deviations of the magnetic needle not being proportionate to the intensity of the currents, the galvanometer must be graduated. To do this, the intensity of the deviations of the needle is noted, whilst the two points of union are maintained at temperatures of which the depressions are known. The author believes, that the application of his thermograph is very easy, and that, by its assistance, the variations of any part of the body can be determined with precision, during a long space of time.

BURNETT ON THE RESONANT FUNCTIONS OF THE EXTERNAL EAR.—Dr. Charles H. Burnett, in an article in the *Philadelphia Medical Times* for April 4, gives it as his opinion, that the auricle, in combination with the meatus auditorius externus, forms a resonator of a more or less conical shape, closed at the bottom by the membrana tympani, the special function of which is to strengthen by reson-

ance those waves of sound which possess a short wave-length, and which are the notes in which the human voice is most rich, and to which it owes its special timbre. Agreeing with Tyndall that the column of air which most easily resounds to any given note is equal to one-fourth of the length of the wave or sound produced by that note, he holds, that the meatus is adapted by its length to act as a resonator for notes from E^{iv} to G^{iv}, which, having from 2,640 to 3,168 vibrations in the second, will have, at 60° Fahr. a wave-length of four and a half inches; when the pitch of the note falls, and accordingly the wave-length increases. Dr. Burnett believes, that, as the meatus auditorius externus is not long enough to act as the resonator, 'the concha is superposed by nature upon the external auditory meatus in order to lengthen it.' He says he has shown this by experiments, made last summer by himself and Dr. A. H. Buck, but he does not in this paper give the methods employed.

W. LAIDLAW PURVES, M.D.

PATHOLOGY.

BERNHARDT ON THE PRODUCTION OF DIABETES IN BIRDS.—The experiments of Bernard upon this subject are by no means very definite in their results. He remarks that puncture of the medulla in birds does not appear to produce the same effects as in mammals, but that this operation is however followed by a singular phenomenon, viz., arrest of digestion (in pigeons). M. Bernhardt (Virchow's *Archiv*, vol. lix. p. 407) has made similar experiments. The pigeons when operated on exhibited the ordinary phenomena, rotation of the head, *mouvements de mande*, etc. When the animals survived the fifth day, they partly regained their appetite and walked somewhat better. In the evacuated excrements, Trommer's test detected sugar plentifully. The pigeons were fed with barley. Further experiments showed, however, that sugar was a normal constituent of the excrements of pigeons fed with barley or peas. The animals were therefore fed with flesh, but in no case in the animals not operated on was sugar found in the excrements. If the pigeons, however, had been fed on flesh, and the medulla were then punctured, the excrements evacuated invariably contained sugar. The animals so operated on exhibited serious disturbance of the nervous system. Often the spasms which occurred after the puncture lasted till the death of the animal (twenty-four to thirty-six hours generally). Often the animals recovered, after they had on the first day fallen to one side or the other in their attempts at walking. After a time they were, with the exception of slight oscillations in walking, quite like sound animals. With one exception, the animals operated upon did not eat of their own accord, but had to be fed artificially. *Post mortem* examination showed either a small or an extended hæmorrhage between the cerebellum and the medulla oblongata, whilst the other organs, beyond the emptiness of the stomach, exhibited nothing in particular. The author also experimented with amyl nitrite to investigate whether this substance produces diabetes in pigeons (as A. Hoffmann has shown to be the case with rabbits) but the results of his experiments were as often negative as positive.

WM. STIRLING, D.Sc., M.B.

BOCK ON SUGAR IN ŒDEMATOUS FLUIDS.—C. Bock (*Reichert und Du Bois-Reymond's Archiv*, 1873, part v.) says that it is well known that a substance capable of reducing oxide of copper has been tolerably constantly found in the cerebro-spinal fluid, and in the fluid of echinococcus sacs. This substance was regarded by M. Bernard as sugar. With special reference to this substance, the author has experimented on œdematous fluids. In cases of anasarca, a lancet-shaped cannula was introduced through the skin, and clear drops of fluid, quite uncontaminated and free from blood, could be caught in a vessel placed for the purpose. In favourable cases, 1,000 cubic centimètres could be obtained daily. In the different diseases which caused the œdema, the fluids differed a little from each other in their physical properties. The fluid was clear, like water, and only seldom was a yellowish or greenish tinge observed, chiefly when icterus was present. Spontaneous coagulation from fibrin did not occur in any case, even after long-standing, or by the addition of defibrinated blood. The reaction was always more or less alkaline; the specific gravity from 1005 to 1010, and this independently of the cause of origin of the œdema. Uræa was constantly found in small quantities (·1 to ·2 per cent.). To test for sugar the albumen must, of course, be removed. The albumen varied in quantity from ·06 to ·9 per cent. In most cases it was ·1 to ·2 per cent. The author employed the various tests for sugar in the most careful manner, and arrived at the conclusion that the substance was really sugar. Quantitative estimations were made with Fehling's solution. In a case of chronic nephritis with pronounced dropsical symptoms, the clear fluid had a specific gravity of 1009, contained only traces of albumen, and ·04 per cent. of sugar; in another similar case ·048 per cent. was obtained. A patient with heart-disease showed ·077 per cent. sugar in his œdematous fluid. Often no sugar was found, but this became more rare the more expert the author became in the investigation. The investigation must always be made on fresh fluid. The author has also found sugar in pleuritic effusions. These results have been compiled by Professor F. A. Hoffmann, from the papers left by Dr. C. Bock at his death.

WILLIAM STIRLING, D.Sc., M.B.

AUDIGÉ ON SPASM OF THE BILIARY PASSAGES. Dr. Audigé's new work on 'Experimental Researches on Spasm of the Biliary Passages,' is based on a certain number of experiments made on dogs. The intention of these experiments was to study the action of mechanical, galvanic, and chemical excitants; and to attempt to reproduce the effects of calculi on the biliary canals, by introducing foreign bodies into them. It was likewise desired to search in the urine for the presence of the colouring matters of the bile during the hours which immediately follow the artificially produced obstruction of the biliary ducts. The last experiments, which are very interesting, have shown that the biliary pigment appears in the urine much before the icteric colouring of the integument, about two or three hours after the ligation of the biliary duct.

PERL ON THE INFLUENCE OF ANÆMIA ON THE NUTRITION OF THE MUSCULAR FIBRES OF THE HEART.—The fatty degeneration of the internal membrane of the vessels, the degeneration of the muscular fibres of the heart, and the arrest of the development of the whole vascular system, are the

three principal organic changes which have been recognised in chlorosis. Already partly pointed out in the collected edition of Virchow's works (*Gesammelte Abhandlungen*, p. 494) these facts are more fully developed in a special memoir on chlorosis by the same author. Since that time, many observers have also recognised the change of the cardiac muscular fibres in a great number of forms of anæmia; for instance, in lying-in-women who had died in consequence of profuse hæmorrhage, and in persons who had died from marasmus after typhoid fever, or from affections of the digestive tube which had brought on serious troubles of absorption or nutrition.

Tschudnowsky, a Russian physiologist, has recently published a memoir, in which he has directly studied the influence of bleeding on the nutrition of the heart; and in which he entirely confirms the results obtained by clinical experience.

Dr. Perl, of Berlin (*Virchow's Archiv*, vol. lviii.), while taking note of these researches, wished likewise to assure himself of the effects of anæmia on the heart, and instituted a series of experiments on dogs, which were superintended by Virchow. He selected veins of a certain size, which were carefully isolated, then tied on the cardiac side. A thread was slipped under the vessel on the peripheral side, then the vein was opened; the desired quantity of blood was allowed to flow, and the operation was finished by tying the peripheric end. Arterial blood was not abstracted, except when the veins, having already been opened several times, had become the seat of thromboses, and consequently more or less impermeable.

Two different methods were adopted. In a first series of experiments, moderate but rather frequent, blood-lettings were performed; that is to say, they were repeated every three or four days, but the quantity of blood never exceeded the hundredth part of the total weight of the animal. In a second series, the blood-lettings were few and far between, but copious. Every five or seven days a quantity of blood corresponding to three hundredths of the entire weight of the animal was taken away.

In the dogs of the first series of experiments, the effects of the blood-letting were very slightly apparent, and recovery was rapid; the appetite was good, the reparation of the blood lost went on smoothly, though the number of bleedings spread over from thirty-six to sixty-nine days had amounted to from ten to seventeen. The animals were killed, and the necropsy revealed a perfectly normal condition of the muscular fibre of the heart; the striation remained perfect; there were no fatty elements except in the neighbourhood of the nuclei, which is an ordinary phenomenon with dogs.

On the other hand, the animals which had been submitted to unfrequent, though copious, blood-lettings (from five to eleven in an interval of from four to twelve weeks) were in a very different condition. They speedily fell into a state of marasmus, rapidly became emaciated, lost their appetite, and their lower extremities became œdematised; all, with one exception, succumbed spontaneously. One dog only did not present any anomalous appearances at the necropsy; in all the others the heart was flaccid, and of a pale and slightly yellowish tint. Fatty degeneration of the muscular fibres could be found in all parts of the organ; sometimes the striation was only interrupted by fatty corpuscles; sometimes it was no longer even perceptible, and only refracting granules, which resisted

the action of acids and alkalis, were to be perceived. The degeneration was not universally distributed in the same degree; it was more decided in the papillary muscles of the left side of the heart, next in the corresponding fasciculi of the right side, next in order came the walls of the left side, and finally those of the right side. The process never showed itself in manifestations which were visible to the naked eye; and with the microscope, by the side of the degenerated fibres, others could be discerned which had remained intact. As the dogs were not suffering from any other disease, and as no clearly defined fibrile movement could be discovered in them, from a clinical point of view, anæmia only could be designated as the cause of the lesions.

From a clinical point of view, these facts are of great importance, since they explain the more or less serious cardiac symptoms which show themselves in inveterate chlorosis. Chlorosis will be removed from the domain of purely humoral pathology to re-enter, up to a certain point, that of organic pathology.

MATERIA MEDICA AND THERAPEUTICS.

HULL ON THE THERAPEUTIC ACTION OF GELSEMINUM.—Dr. W. C. Hull, of Monroeton, Pennsylvania, writes (*Philadelphia Medical Reporter*): When we proceed to investigate the therapeutic powers of a new agent, there are two general heads under which our studies should be conducted.

1. Prove its effects on a healthy organism.
2. After having determined its physiological action, proceed upon general principles to elicit its remedial powers. A knowledge of drug action on the healthy organism enables us to form some idea of its adaptability to morbid states; but it may still have occult curative powers, which can be discovered only by empirical tests. The action of the sulphate of quinia in health affords no indication of its specific power over ague; but the sleep and insensibility produced by opium present sufficient evidence of its ability to relieve insomnia and pain. There are numerous sources of error, which are apt to mislead us in the study of practical medicine. The 'vis medicatrix nature' must not be lost sight of by the attentive and candid investigator. Perhaps there is no mistake more frequently made by physicians, than the one of attributing cures to remedial action which are really due to natural effort. In the larger proportion of cases we are called to treat, the natural tendency is to health, for within certain limits the human organism embraces within itself the elements of recuperation.

The question arises, how can we, in a given case of recovery under treatment, determine the relative amounts of recuperative and of remedial power? The fact is, we can never isolate the two forces; recuperative power is the germ of all cures; hygiene and medicine do no more than to develop this conservative principle of life into more potent energy. In some cases of disease, life would undoubtedly be sacrificed without appropriate treatment, but instances of this kind are far less numerous than was formerly supposed. The expectant plan of treatment, which has been thoroughly tested during the last few years, has established the fact that the sick recover without treatment in a large proportion of curable diseases.

The actual curative power of medicinal agents can only be determined by their repeated use in the same disease, and then comparing the general result with the expectant plan of treatment in a like number of cases. So far as attainable, this comparative method gives us the absolute value of remedies, which is the very thing we ought to know, in order to avoid drugging our patients to no purpose, or to their irreparable injury.

It has been frequently demonstrated by the absolute test, that some popular modes of treatment prolong instead of cutting short the progress of disease; hence, I insist upon the importance of comparing medicinal with expectant treatment. Relative medicinal tests are valuable, when it has been proved that the agents compared do not prolong but abridge disease. I have introduced these preliminary observations, in order to stimulate investigators to prove, so far as possible, the absolute powers of medicinal agents.

Gelseminum Sempervirens, yellow jasmine, was used throughout the Southern States as a vermifuge, in domestic treatment, long before its special affinity for certain forms of fever was discovered. Its first use in the treatment of fever was the result of a mistake made by the servant of a Mississippi planter, for a full account of which see *U. S. Dispensatory*, page 421. According to my observation, the most obvious effects of gelseminum on the human organism are, vertigo, slight delirium, pupillary dilatation, amblyopia, diplopia, congestion, general prostration, muscular relaxation and diaphoresis. The four conditions of the ocular organs, congestion, amblyopia, diplopia, and pupillary dilatation, indicate a diminution of nervous force, which results in partial paralysis. It is my opinion that, in order of sequence, the congestion (a result of vasomotor enervation) occurs first, and the three other conditions supervene in consequence of obstructed capillary circulation. There is not evidence sufficient to prove that gelseminum acts directly on the cerebral ganglia. Physiology has established the fact that the circulation of the blood through the capillary vessels is effected to a considerable extent by the natural tonicity of their coats. This tonicity of the capillary coats is dependent upon the vasomotor fibres of the great sympathetic; so whatever impairs the function of this nerve must produce capillary congestion. Gelseminum acts directly on the great sympathetic, diminishing the amount of nervous force transmitted through the vasomotor system of nerves to the capillary vessels, impairing their tonicity and producing congestion.

The secondary effects are such as we might expect from an interrupted circulation, viz., general prostration, muscular relaxation with debility, and a feeble, slower action of the heart. It is asserted by some writers that gelseminum is an arterial sedative, but this is an obvious error. Veratrum viride is a good example of a true arterial sedative; it acts directly on the heart, diminishing the frequency and force of its action. Gelseminum acts directly on the capillary vessels, impairing their tonicity, and obstructing the flow of blood through them. Veratrum viride acts upon the central, while gelseminum acts upon the peripheral portion of the vascular circle.

Although both agents, in a different order, restrain the action of the heart, their range of application to the treatment of disease is widely different. Veratrum is adapted to the treatment of congestive and inflammatory diseases, for, by directly restraining the

heart's action, less blood is forced into the weakened and distended capillaries, and resolution is facilitated. Gelseminum is not indicated in the treatment of those conditions, as it indirectly restrains the heart's action by first producing general capillary congestion, a morbid state which always aggravates existing local lesions. Its use in congestive diseases would be similar to the act of throwing benzine into a fire, with the expectation of putting it out. The peculiar action of gelseminum on the nervous system affords no indication of its specific curative powers in certain fevers. Its occult virtues were first discovered by accident, and subsequently more fully developed by empirical tests. Since my location in Monroeton, less than three years ago, I and my late partner, Dr. D. N. Newton, have used gelseminum in at least one thousand cases of the diseases incident to this section. The general conclusion we have reached regarding it may be thus epitomized.

1. It is not adapted to the treatment of inflammatory and congestive diseases.

2. It inflicts positive injury in active congestion.

3. Its therapeutic scope does not extend much beyond certain simple forms of fever.

4. In order to obtain its specific action in fever, it must be rapidly introduced into the system, until its characteristic effects are produced upon the organ of vision.

5. It can be given in full doses, with entire safety, in those cases to which it is adapted.

I will not attempt to enumerate the various forms of disease in which gelseminum has either failed to evince any curative action, or has proved to be inferior to other remedies, but content myself with naming the affections which, in my hands at least, it has certainly benefited. In bilious, catarrhal, and the gastric fevers of childhood, it is nearly a specific. In typho-malarial fever, when there is a marked predominance of the malarial character, it often aborts it. I usually give five drops of the fluid extract every two hours, according to the effect. Usually at some period within twenty hours, the patient begins to complain of vertigo, double vision, impaired sight, muscular weakness and languor; a little later, a copious sweat comes on, and the fever, if simple and free from local lesions, is broken, and returns no more.

BURDEL ON EUCALYPTUS AND ITS FEBRIFUGE QUALITIES.—Dr. E. Burdel, Physician to the hospital at Virgon, records in the *Revue des Sciences Médicales*, April, 1874, the results of his observations on the action of eucalyptus in the Sologne. The results of Dr. Burdel's first cases were recorded in the *Bulletin Générale de Thérapeutique*, vol. lxxxiv. p. 409.

In the second note, now under consideration, upwards of thirty-three cases are reported, in which eucalyptus was successful in eighteen instances. M. Burdel believes that he can now, after two years' experience, by bringing together the facts which have occurred under his observation, arrive at the following conclusions with regard to the employment of eucalyptus.

The action of this remedy, which may certainly be considered a febrifuge, is slow and far from being always constant. In mild intermittent fever, eucalyptus is successful in four-fifths of the cases; in tertian, in three-fifths only; and, finally, in quartan fevers, it almost entirely fails: that is to say, in eight-tenths of the cases. In the seasons when intermittent fever

is most frequent—that is to say endemic—relapses are much more common when eucalyptus is used, than when recourse is had to quinine. Relapses may, however, be avoided by administering eucalyptus more frequently after some days rest only, and in as large doses as the stomach will tolerate. This remedy is perfectly inert in palustral cachexia. Finally, M. Burdel believes that in the second year of his experiments he obtained a rather larger proportion of cures and a smaller number of relapses, because he gave the eucalyptus in conjunction with good wines, iron, and quinine, and kept the organism up to its work by frequently repeated doses. Dr. Burdel administered the alcoholic extract of eucalyptus in pills, each containing 15 centigrammes, to the number of from four to ten daily, according to the form of the fever, given twice during the day.

ANDREWS ON COD-LIVER OIL EMULSION.—Dr. Beard writes (*Boston Medical Journal*, April 9): 'The prescription of a cod-liver oil emulsion was originally given by Dr. J. B. Andrews, of the Utica Insane Asylum. I have modified this prescription in various ways, and have experimented with it quite largely, and have recommended it to many of my professional friends. It takes a long time to make it, and the majority of druggists will slight it unless they are assured it will be ordered in large quantities. The latest modification that I employ is the following. If desired, Fowler's solution may be added to it. One of my patients, a physician, has added strychnine to it.

| | |
|--------------------------------|----------|
| R.—Glyconin | 3ix. |
| Ol. morrhue | 3iv. |
| Spts. ammon. arom. | 3i. |
| Vini xerici | 3ij. |
| Acid. phos. dil | 3ss. |
| Ol. amygdal. amar. | gtt. ij. |
| dissolved in alcohol | 3ij. M. |

'Put the glyconin first in the mortar, then add the oil by drops, stirring briskly all the time. When this process is completed, you will have a mass looking like, and having the consistency of, soft butter. Then add the other ingredients in the order mentioned; add them slowly, stirring all the time. The glyconin is made by beating yolks of eggs with a spatula until they are well broken, then add an equal measure of glycerine. It requires one or two hours to make it.

'The above preparation, when properly prepared, robs cod-liver oil of its terrors. The taste of the oil is pretty nearly destroyed, and no one, however fastidious, objects to it. When properly prepared, it will keep for months, if not years. Mr. Close, a pharmacist of Brooklyn, who introduced the glyconin modification in the emulsion, lets the oil drop out of a small bottle through a glass tube, and thus avoids the danger of pouring it in too fast. This emulsion, when made according to the above directions, with sufficient care, time and labour, is without question the best emulsion of the kind now before the profession. The original prescription, of which the above is a modification, is, or was, used in the Utica Insane Asylum in large quantities, and with satisfactory results. One druggist, to whom I gave the prescription, makes several gallons at a time and keeps it always on hand. Consumptives, who must take cod-liver oil, and yet cannot bear it, find this emulsion agreeable, and, as far as I can learn, as useful as the oil when taken alone.

'My own experience with the emulsion has been confined mostly to its use in hysteria, neurasthenia, and allied affections, and I know no single prescription that does so much good and so little harm in all these aneuric disturbances. I earnestly recommend it to the profession, and especially to those who are giving special attention to diseases of the nervous system.

'The dose ranges between a desertspspoonful and two tablespoonfuls. If it tastes badly and keeps badly, the fault is in the druggist.'

OBSTETRICS AND GYNÆCOLOGY.

BRAUS ON PYOMETRA AND PYOKOLPOS LATERALIS FROM ABRASION OF A RUDIMENTARY VAGINA, IN A CASE OF UTERUS BICORNIS.—Dr. Otto Braus (*Berliner Klinische Wochenschrift*, March 9 and 16, 1874), reports a very interesting case occurring in the practice of Professor Spiegelberg. The person was twenty-six years old. She began to menstruate at fourteen. The catamenia continued regularly for a year and a half; then there was an arrest for six months, during which time she began to suffer from pressure on the rectum and bladder. On the return of the catamenia, this still continued. A tumour was made out by the medical attendant, and opened. No fluid came away, and she obtained no relief.

Another medical man was consulted, who punctured the swelling and evacuated a quantity of dark, syrupy blood. This gave immediate relief, and she continued quite free from all trouble until her marriage, which was about a year and a half before she came under the observation of Professor Spiegelberg, when she began again to suffer from pressure on the bladder and rectum, accompanied with dysmenorrhœa. She became pregnant nine months after marriage, and miscarried at three months. On her recovery she noticed a puriform discharge, which increased in quantity and became offensive. Whenever it stopped, she at once experienced discomfort in the bladder and rectum, with a forcing down of the womb. On examination, Professor Spiegelberg found a movable somewhat irregular elastic swelling, larger than a fist, situated in the front and towards the right side of the pelvis; it reached slightly above the anterior wall of the pelvis, and caused the anterior vaginal wall to project downwards. The cervix was pushed backwards and to the left, and discharged a copious purulent offensive matter. The uterine sound passed the normal distance to the left. As pressure on the tumour increased the flow from the os, the uterine sound was again passed with its point turned to the right. About two centimètres up the canal it slipped into a roomy cavity. A blunt-pointed bistoury was passed up the cervix, and an opening about an inch long made. The sac was emptied of a quantity of pus, and small stony hard blood-concretions. A distinct entrance into the left horn of the uterus could be felt; and about a centimètre-and-a-half above the os a fleshy septum with a free border.

This relieved, but did not cure, the trouble. The sac was then slit down to the bottom with scissors. Upon examination, a right and a left inner os could be distinguished. The walls of the cavity had all the characters of vaginal structure. Per rectum, the bicornate uterus could be easily defined; the uterine sound passed four centimètres into the right

horn. It was a case of uterus bicornis, with a cervix in common. The history proved that it could neither be a hæmatocele nor a cyst, the result of an abscess from parametritis.

The reporter of this case relates two somewhat similar instances occurring in the practice of Professor Breisky. One patient was a woman, twenty-five years old, the other was thirty-eight years old. The latter had borne four children before any urgent symptoms arose to attract attention. In both were the tumours slit up, and the patients made excellent recoveries. The diagnosis is not easy. It was not until the cavity was opened, and the free border of the septum was felt by the finger, together with the point of bifurcation per rectum, that Professor Spiegelberg could be certain what he had to deal with. He was not a little indebted to the cases reported by Professor Breisky for coming to a right conclusion. It was not until the sac was emptied that the bifurcation of the cervix could be felt.

W. C. GRIGG, M.D.

MISCELLANY.

THE GERMAN PUBLIC HEALTH CONGRESS will be held in Dantzic from September 9 to 12. Among the subjects to be discussed are the following:—1. The demands of hygiene with regard to new portions of towns, streets, and houses; 2. The influence of various dwellings on the health of their inhabitants; 3. The reasons for and against the collection of cases of various kinds of disease in one hospital; 4. Public abattoirs; 5. Water supply; 6. The employment of women in factories.

CREMATION.—The advocates of cremation in Bremen have raised money for a prize on the best economic and æsthetic means of performing the process. The essays must contain (1) Descriptions, and as far as necessary, drawings (models being subsequently added), of buildings and apparatus for the purpose of burning, with statements of cost; (2) Descriptions of the process of cremation, with a sufficient exposition of the experiments on the bodies of animals or men, on which the proposals are founded; (3) Estimates of the cost of cremation. The essays may be written in German, English, or French.

EDINBURGH MEMORIAL TO LIVINGSTONE.—It is proposed to erect a Medical Missionary Training Institution in Edinburgh as a memorial to Dr. Livingstone. The present Medical Missionary Institution in that city is the only one of its kind in the kingdom, and has furnished agents to all the chief missionary societies of this country; but it has outgrown its present premises in the Cowgate, and the committee are desirous of having a more commodious building wherein to carry on the training of medical missionaries and missionary nurses. They propose, therefore, to seize this opportunity of erecting a building which would be a suitable memorial to the greatest medical missionary whom this country has ever sent forth, and whose name is so peculiarly dear to Scotland. An influential meeting was held in Edinburgh last week to promote this object, and we have no doubt that it will be successfully carried out. The amount required is large, namely, 10,000*l*. But the committee have ascertained that it is a form of memorial which would be gratifying to the feelings of the family of the deceased; and Sir Bartle Frere has expressed his approval in the following terms: 'I have always felt that the Edinburgh Medical Missionary Society was doing a great work, and I am very glad to hear that you propose to enlarge its sphere of usefulness. I think there could not be a more fitting memorial to your great fellow-countryman; and with such an example before them I think the students of the Medical Missionary Society must prosper wherever they are sent. The thorough

training of good nurses to co-operate with the missionaries abroad is all that is needed to perfect the work of the society.' With such sanctions as these the appeal will recommend itself to a very wide circle, and the requisite sum of money is sure to be subscribed.

HOW SHALL YOUNG LADIES BE FLOGGED?—A Dublin physician has lately written to a medical contemporary explaining that he has been appointed to a good ladies' school in a large country town, and has been asked by the principal what mode of correction he would recommend as least likely to prove injurious to the young, but, it is to be feared, somewhat recalcitrant damsels under her charge. The physician seems to have been somewhat exercised in mind by this unexpected inquiry, and seeks information on the subject from 'experienced' readers. He fears that long impositions and confinement would be detrimental to the health of the fair rebels, and seems to lean to the heroic remedy of the birch, perhaps from remembrances of its efficacy in his own school-days. He 'partly' recommends a leather strap for the hands as preferable to the ruler or the cane. The 'physician' appears to contemplate the possibility of somewhat severe punishment being required in dealing with the Hibernian young ladies in question; since he goes on to ask if there is 'any risk in flogging a girl on the shoulders,' as 'a scar there would possibly prevent her appearing in evening dress for years.' Reverting to his favourite birch, he wishes to determine which is the more useful, that, or the leather strap; and challenges advice as to the employment of a slight riding-whip or 'riding-rod,' as it is termed by the amiable disciplinarian in charge of the school. We had thought that corporeal punishments were unknown in girls' schools, and greatly

on the decrease in boys; perhaps, however, the greater vivacity of the denizens of the sister isle requires very forcible measures of repression. As may be readily imagined, the queries of this undecided 'physician' evoked a shower of answers. One indignant lady suggested that the unfortunate medical adviser of ladies' schools should try the experiment of the various chastisements he so calmly suggests for the young girls on his own person; winding up with a recommendation that he should be flogged with nettles. Another correspondent recommends that all the floggings, whether with birch, ruler, or strap, should be applied outside the clothes, so as to avoid any danger of scars, and a third supplements the list of instruments of punishment by recommending the use of the slipper, or ladies' shoes, as having the merit of being always in readiness. For our own part, we should emphatically recommend that the directress of a school for girls who could ask such questions, and the medical man who could for one moment think of giving a serious reply to them, should be immediately removed from responsible positions, which on their own showing they are entirely unfit to hold.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, MAY 20, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

BINZ AND HELMHOLTZ ON THE TREATMENT OF HAY-FEVER.

We reproduce from *Nature* the following paper on hay fever, by Professor Binz, of Bonn.

From what I have observed of recent English publications on the subject of hay fever, I am led to suppose that English authorities are inaccurately acquainted with the discovery of Professor Helmholtz, as far back as 1868, of the existence of uncommon low organisms in the nasal secretions in this complaint, and of the possibility of arresting their action by the local employment of quinine. I therefore purpose to republish the letter in which he originally announced these facts to myself, and to add some further observations on this topic. The letter is as follows (see Virchow's *Archiv*, vol. xlv.)

'I have suffered, as well as I can remember, since the year 1847, from the peculiar catarrh called by the English "hay-fever," the speciality of which consists in its attacking its victims regularly in the hay season (myself between May 20 and the end of June), that it ceases in the cooler weather, but on the other hand quickly reaches a great intensity if the patients expose themselves to heat and sunshine. An extraordinarily violent sneezing then sets in, and a strongly corrosive thin discharge, with which much epithelium is thrown off. This increases, after a few hours, to a painful inflammation of the mucous membrane and of the outside of the nose, and excites fever with severe headache and great depression, if the patient cannot withdraw himself from the heat and the sunshine. In a cold room, however, these symptoms vanish as quickly as they come on, and there then only remains for a few days a lessened discharge and soreness, as if caused by the loss of epithelium. I remark, by the way, that in all my other years I had very little tendency to catarrh or catching cold, while the hay-fever has never failed during the twenty-one years of which I have spoken, and has never attacked me earlier or later in the year than the times named. The condition is extremely troublesome, and increases, if one is obliged to be much exposed to the sun, to an excessively severe malady.

'The curious dependence of the disease on the season of the year suggested to me the thought that organisms might be the origin of the mischief. In examining the secretions I regularly found, in the last five years, certain vibrio-like bodies in it, which at other times I could not observe in my nasal secretion. . . . They are very small, and can only be recognised with the immersion-lens of a very good Hartnack's microscope. It is characteristic of the common isolated single joints that they contain four nuclei in a row, of which two pairs are more closely united. The length of the joints is 0.004 millimètre,

Upon the warm objective-stage they move with moderate activity, partly in mere vibration, partly shooting backwards and forwards in the direction of their long axis; in lower temperatures they are very inactive. Occasionally one finds them arranged in rows upon each other, or in branching series. Observed some days in the moist chamber, they vegetated again, and appeared somewhat larger and more conspicuous than immediately after their excretion. It is to be noted that only that kind of secretion contains them which is expelled by violent sneezings; that which drops slowly does not contain any. They stick tenaciously enough in the lower cavities and recesses of the nose.

'When I saw your first notice respecting the poisonous action of quinine upon infusoria, I determined at once to make an experiment with that substance, thinking that these vibrionic bodies, even if they did not cause the whole illness, still could render it much more unpleasant through their movements and the decompositions caused by them. For that reason I made a neutral solution of sulphate of quinine, which did not contain much of the salt (1:800), but still was effective enough, and caused moderate irritation of the mucous membrane of the nose. I then lay flat on my back, keeping my head very low, and poured with a pipette about four cubic centimètres into both nostrils. Then I turned my head about in order to let the liquid flow in all directions.

'The desired effect was obtained immediately, and remained for some hours; I could expose myself to the sun without fits of sneezing and the other disagreeable symptoms coming on. It was sufficient to repeat the treatment three times a day, even under the most unfavourable circumstances, in order to keep myself quite free.* There were then no such vibrios in the secretion. If I only go out in the evening, it suffices to inject the quinine once a day, just before going. After continuing this treatment for some days the symptoms disappear completely, but if I leave off they return till towards the end of June.

'My first experiments with quinine date from the summer of 1867; this year (1868) I began at once as soon as the first traces of the illness appeared, and I have thus been able to stop its development completely.

'I have hesitated as yet in publishing the matter, because I have found no other patient† on whom I could try the experiment. There is, it seems to me, no doubt, considering the extraordinary regularity in the recurrence and course of the illness, that quinine had here a most quick and decided effect. And this again makes my hypothesis very probable, that the vibrios, even if being no specific form but a very frequent one, are at least the cause of the rapid increase of the symptoms in warm air, as heat excites them to a lively action.'

I should be very glad if the above lines would induce medical men in England—the haunt of hay-fever—to test the observation of Helmholtz. To most patients the application with the pipette may be too difficult or impossible; I have therefore

* There is no foundation for the objection that syringing the nose could not cure the asthma which accompanies hay-fever; for this asthma is only the reflex effect arising from the irritation of the nose.—*Binz*.

† Helmholtz, now Professor of Physics at the University of Berlin, is, although M.D., not a medical practitioner.—*B*.

already suggested the use of Weber's very simple but effective nose-douche. Also, it will be advisable to apply the solution of quinine *tepid*. It can, further, not be repeated often enough that quinine is frequently adulterated, especially with cinchonia, the action of which is much less to be depended upon.

Dr. Frickhöfer, of Schwalbach, has communicated to me a second case in which hay-fever was cured by local application of quinine (Virchow's *Archiv*, vol. li.). Professor Busch, of Bonn, authorises me to say that he succeeded in two cases of 'catarrhus æstivus' by the same method: a third patient was obliged to abstain from the use of quinine, as it produced an unbearable irritation of the sensory nerves of the nose. In the autumn of 1872, Helmholtz told me that his fever was quite cured, and that in the meantime two other patients had, by his advice, tried this method, and with the same success.

KÜSTER ON THE INFLUENCE OF THE NEW RIFLES ON THE ANIMAL BODY.

In a communication made to the Berlin Medical Association, by Dr. Küster, Surgeon to the Augusta Hospital, Berlin (*Separat Abdruck aus der Berliner Klinischen Wochenschrift*, 1874), the author first refers to the experiments and inquiries of Professor Busch, of Bonn, who found that the Chassepot ball, fired from short distances, made most frightful wounds in the human body. The wound of entrance might be small, but that of exit was often of the size of a man's fist, accompanied by the most extensive smashing of bone. Busch concluded from this that the ball was actually in part melted by the sudden arrest of its very high rate of velocity. The author, in experiments he performed in the winter of 1872-3, obtained similar results to those of Busch, but he does not think the explanation given the correct one.

In order to further investigate the matter, Dr. Küster obtained permission from the Ministry of War to undertake the necessary experiments at Spandau. The animals used were horses and sheep, and the weapons tested, a muzzle-loading sporting gun with conical balls, and the needle gun (*Zündnadel*), Chassepot, Mauser, and Henry-Martini rifles. The distance at which these weapons were fired, were 5, 20, 100, and 800 paces.

A salvo was first fired from the various rifles at the same moment, which killed the animal, and then the dead body was further fired into. At the end of eight days the already somewhat decomposed body was again fired at. A large number of experiments were made in this way.

Amongst the results obtained were the following.

1. The projectile caused no appreciable difference as regards the wound, whether fired at the dead or the living body. It should be borne in mind that the animal skin resists much more than the human the entrance of the projectile, and the exit-wound is relatively not so large as in the human body.

2. The amount of injury is inversely as the distance, and in direct proportion to the velocity of the projectile. The balls delivered from the sporting gun generally lodged, and produced but trifling injury. Next in intensity were the wounds produced by the Needle-gun. The Chassepot caused yet more extensive injury, whilst the Mauser produced complete destruction of bone and soft parts through a large extent.

3. The extensive character of the wound so produced is due to the sudden heating of the lead causing it to lose its cohesive power, but not, as Busch believed, actually to melt. Hence small particles are detached, and remain adherent to the bones and soft parts. The ball is flattened, twisted, and divided into two or several portions; and in this fashion, accompanied by bone-fragments, makes its exit from the body. That the lead is merely softened, and not actually melted, the following experiment of Schädel, in Heidelberg, would seem to establish. He fired at an iron target on which he had hung some bags of powder. The bags were often burst, but in no instance did an explosion take place, which must have occurred were the lead heated sufficiently to become melted; besides, the maximum of heat was thus developed, which would not occur in the animal body where the flight of the projectile is only partially and gradually arrested. That lead does lose its coherence when heated, is easy to prove by dropping two bullets, one strongly heated, the other cold, a height of some six feet to the ground; the heated bullet will be distinctly flattened, while the other remains unaltered. The huge wounds, then, produced by leaden bullets fired with great velocity at short distances, arise from the splitting up of the bullet into pieces, after striking a bone, owing to the loss of cohesion due to the heat developed by the sudden retardation of velocity. These fragments of lead, and pieces of bone carried along with them, make the extensive damage uniformly witnessed under the foregoing circumstances. It only remained for Dr. Küster to show that bullets composed of harder metal did not occasion the damage created by the ordinary leaden bullet. It appears that our Henry-Martini rifle affords the desired conditions. From it is fired a bullet formed from an amalgam of lead and tin, in the proportion of twelve parts to one. The metal is first cast in long rods, then cut to the proper lengths and finally compressed in a mould. The velocity of the projectile is about the same as that of the Mauser rifle, but the damage done is infinitely smaller. The wound of entrance in the bone in the case of the latter rifle is often large, irregular, and much splintered, the destruction gradually increasing in amount towards the wound of exit; while the Henry-Martini bullet always makes a sharp cut circular opening in the bone of its own diameter in size. The wound of exit is larger but is also round, and splintering of the bone is either altogether absent or but very limited. The ball is but seldom deformed. At a hundred paces the Henry-Martini bullet goes right through the bulkiest part of the horse, while the Mauser bullet lodges. Of course a lodged bullet must always prove a source of anxiety and danger.

Amongst the conclusions drawn by the author, one is, that from a medico-legal point of view there is no appreciable difference between gunshot wounds inflicted before and after death. It is easy, especially if the bone be traversed, to distinguish between a wound inflicted by a hardened or a leaden bullet, or whether it was caused by a weapon discharged at a short or a long range. The knowledge thus gained may prove of great assistance in deciding whether in a given case amputation is needed or not. The author likens the soft leaden bullets to explosive bullets, and thinks they should be equally banished from use as weapons of war. Cases occurred during the last war, where it was firmly believed, the damage done being so enormous, that explosive

bullets must have been employed. The author considers that his experiments establish a satisfactory explanation of this apparent infringement of the rules of civilised warfare, if indeed war can in any respect be called civilised.

WILLIAM MAC CORMAC.

PRACTICAL SURGERY.

TREATMENT OF HÆMORRHOIDS BY LINEAR CAUTERISATION OF THE ANUS. BY DR. WOILLEMIER.

After having written an exact history of all the methods of treating hæmorrhoids, and after having either tried the greater number of them in private or hospital practice, M. Woillemier (*L'Union Médicale*) has finally fixed on the following rational procedure, as removing all dread of the operation both in the operator and in the patient.

The patient, whose rectum has been emptied in the morning by means of an injection, ought to be chloroformed; but if he prefer to remain awake, it is of little importance, as the operation only lasts some seconds. He is laid on the edge of a bed, with one leg extended, and the other bent as if he were going to be operated on for fistula. The assistant raises the disengaged buttock, the surgeon paints the anus and the surrounding parts largely with collodion, whilst an assistant, by means of bellows, drives off the fumes of the ether, which are sure to catch fire when a highly heated cauteriser is brought near them. During these preparations, two knife-shaped cauterisers have been placed in a small furnace, full of charcoal or burning wood. The blades of these cauterisers should be two centimètres long and one wide; the tip and edge should be blunt, as in ordinary cauterisers, but the back should be four or five millimètres thick, so as to hold enough heat. The surgeon takes one of these cauterisers when it is white-hot, and introduces it about one centimètre into the anus, bearing with the shoulder of the instrument rather more on the cutaneous than on the mucous orifice, and makes four cauterisation lines, before, behind, on the right and on the left. The operation is terminated when it has lasted five or six seconds. The patient is brought back to consciousness, and simple water-dressings only are applied to the anus. We must premise that, under the influence of the congestion produced by cauterisation, the hæmorrhoidal tumour will reappear the first day or so, and sometimes larger than usual, but no notice must be taken of it. We can only relieve the pain of the patient, pain which has no relation to the cauterisation, by coating over the hæmorrhoids with a narcotic ointment, and covering them up with a poultice. The tumour soon ceases to be painful, and is at last completely and spontaneously retracted. The time necessary for cure varies only according to the size of the hæmorrhoids, the relaxation of the anus, and the age of the patient. It has never exceeded one month, and has sometimes been much less. In some subjects, even when circumstances have made success doubtful, cure has taken place as in simple cases. The patient ought to be chloroformed, for, though the operation is rapid, it is also very painful, particularly in private practice, where the assistance is less efficient than in an hospital. The patient may struggle after one or two applica-

tions of the cautery, and even refuse to allow others to be made, so that the operation would remain incomplete. The orifice of the anus and the surrounding parts must be painted with collodion. This is a very important precaution. All surgeons have affirmed the difficulty of preventing the effects of radiating heat. To preserve the parts from these effects, cloths steeped in cold water and thin plates of wood have been used; but not only are these in the operator's way, but they are not, as a rule, efficacious. Collodion, on the contrary, even when applied in a thin layer only, forms an artificial epidermis scarcely permeable to heat and sufficiently protecting the skin.

It is necessary to dissipate the ether-vapour, or it would take fire as soon as the heated cauteriser is brought near the anus. The accident would not be of much importance, for the burning vapour is easily extinguished by blowing it out; but it is better to avoid it altogether. It is easy to understand the importance of the use of collodion in relation to the pain which succeeds the operation. The patient cannot feel pain in the points to which the iron has been applied, for the tissues are dead, but he suffers in the surrounding parts which have been attacked by the radiating heat, and the painful nature of superficial burns is well known. These burns, however, are not very serious, and only last about four days, at the time when the inflammation necessary for the falling off of the sloughs develops itself, or during defecation after the sloughs have fallen off. The cauterisers ought to be knife-shaped, or even with round points. To ensure the rapidity of the operation, they should be heated to white heat. One operation is frequently enough, but more than two are never necessary, how large soever the hæmorrhoidal tumour may be, for we do not act directly on the latter, but on the anus.

In some cases, the tumour cannot be reduced before operation, or at least entirely so, when it still escapes outwardly in consequence of the involuntary contractions of the patient. No notice must be taken of this accident. The cauteriser is slipped between the tumour and the walls of the anus, for it is of little consequence if the hæmorrhoids should be lightly cauterised by the back of the instrument.

Sometimes the shoulder of the cauteriser implicates the cutaneous circumference of the anus, but that is of no importance; it is even sometimes useful when the anus is considerably relaxed. There is no need to dread hæmorrhage, for the cauteriser interferes only with the mucous membrane, the submucous cellular tissue at the entrance of the anus, and the skin at the edge of the orifice. At all these points the vessels are small, and when the hæmorrhoidal tumour is touched by the back of the cauteriser, it is in so light a manner that no vessel of any importance can be opened.

If any accident is to be feared, it would be stricture of the rectum; but the four cicatrices which have been formed at the entrance of the anus, although possessed of great retractile power, are made linear in the direction of the intestine. Between them are intervals, occupied by highly elastic tissue, which make stricture impossible. It may be objected that, if the anus remain sufficiently dilatable, the patient may have a relapse. This accident is certainly not impossible, but it is the business of the surgeon to estimate the state in which he finds his patient. If he be going to operate upon an old person having a large and old standing

tumour, and whose anus has little resilient power, he should lean a little more heavily on the cauteriser, so as to implicate a greater thickness of tissues than in ordinary cases; and by this procedure he will be sure to avoid a relapse.

ANATOMY AND PHYSIOLOGY.

GIACOMINI ON A LARGE COMMUNICATION BETWEEN THE VENA PORTÆ AND THE ILIAC VEINS ON THE RIGHT SIDE.—Dr. Giacomini read, at the Academy of Medicine at Turin, on November 28, 1873, the history of a woman, aged twenty-two, who had had intermittent fever, with enlargement of the spleen, and was admitted into the hospital for bronchopneumonia and hydrothorax. She was recovering after paracentesis thoracis, but was much troubled with enteralgia and headache, when one day, after a surfeit, she raised herself suddenly in bed, fainted, and remained in a prostrate condition for half-an-hour, when she died.

The cranial and thoracic organs presented nothing to note, except miliary tubercles of the lungs.

The spleen was enormously enlarged, its lower end resting on the left iliac fossa. On the inner edge of the spleen was a large tumour formed of semi-clotted blood, contained between the layers of the gastro-splenic omentum. This extravasation seemed to have been the cause of death. There was catarrh of the lining membrane of the stomach.

On trying to turn down the right side of the abdominal parietes, a large canal was noticed, which was taken at first for an empty convolution of small intestine, but was seen, on more attentive examination, to come out of the pelvis on the right side of the pubes and pass between the two layers of the suspensory ligament of the liver, running along with the obliterated umbilical vein through the longitudinal to the transverse fissure.

The liver was cirrhotic, and on microscopic examination, its portal capillaries were found obstructed. The ductus venosus was obliterated.

On more minute examination of the parts, the splenic vein was found to have a diameter of 16 millimètres (= .63 of an inch) and presented a slight enlargement of its posterior wall, just before receiving the inferior mesenteric vein. The superior mesenteric vein was a little smaller than the splenic (12 millimètres), the vena portæ somewhat larger (18 millimètres = .7 inch). The right branch of the vena portæ was natural. The left branch, much more voluminous than the right, presented a dilatation into which the umbilical vein was inserted. The latter was completely closed and obliterated. Other veins, communicating with this branch of the vena portæ, entered the liver, and of these two, after traversing the parenchyma of the liver, reunited and formed the canal which had been taken for a convolution. This large vein ran down in the suspensory ligament, above the round ligament, and furnished a branch of the size of the internal saphenous to the right inferior phrenic vein, by means of which it opened into the vena cava in its passage through the diaphragm. It ran to the umbilical depression or cicatrix along with the umbilical vein, being covered by the peritoneum and by the 'fascia umbilicalis,' described by Richet (unusually developed in this subject), then became tortuous, and passed into the sheath of the rectus muscle. Here it divided into two, which ran down

as the venæ comites of the epigastric artery, after receiving the venæ comites of the upper part of that vessel. Besides these, there were other branches which do not need any more particular description. At Poupart's ligament, a large part of the vein entered the external iliac at the usual point of junction of the epigastric vein, but two branches were given off, which united and joined the obturator vein to open into the internal iliac. The volume of the external iliac vein was enormously increased by the junction of this great vein from the liver, but there was no irregularity in its distribution. There was no dilatation of the hæmorrhoidal veins, nor any pronounced hæmorrhoidal formation. The appearance of the abnormal veins strongly indicated that the direction of the current in them had been by reflux from the portal veins into those communicating through the iliacs with the vena cava.

The author regards this anatomical anomaly in three points of view; 1. With regard to the changes which the reflux of blood from the portal vein may have caused in the viscera, and especially the lesions which produced death; 2. With regard, generally, to the re-establishment of circulation after the portal circulation is interrupted; 3. With regard to the arrangements in the normal anatomy to favour the re-establishment of a collateral circulation in conditions of disease.

1. In the first place, he points out the way in which cirrhosis of the liver acts by throwing the blood back on the portal radicles, causing ascites, increased volume of the spleen, and hæmorrhage from some of the congested veins—and he refers to Raikem for a collection of such observations.* Such hæmorrhages usually act primarily through the vessels in the gastro-intestinal mucous tract. In this instance the large vein or veins which gave way must have been connected with the vasa brevia entering the splenic vein; and he believes that the enormous weight of the spleen had its influence in producing the rupture, having ascertained that the patient just before her death had made an abrupt movement of the body after a very hearty meal.

2. The ways by which, in such portal obstruction, the blood finds an anastomosis with the system of the vena cava, are various. The communications of the hæmorrhoidal and œsophageal veins are well known. Schniedel† has pointed out some which are less known—of the hæmorrhoidal with the vesical veins, of the coronaria ventriculi and gastro-epiploic with the renal, of the vasa brevia with the left inferior phrenic, of the pyloric with the right inferior phrenic, of the superior mesenteric and left renal. And besides these communications, which are formed by anastomosing branches of some size, Retzius‡ has described (and his descriptions have been confirmed by Hyrtl) numerous capillary communications at various parts of the abdominal parietes.

3. The normal anastomoses may become dilated in conditions of disease, though the dilatation usually passes unobserved in consequence of the vessels not having been injected before the *post mortem* exami-

nation. He refers, however, to cases published by Gubler,* Lyons,† Virchow,‡ and Hyrtl,§ in which one or other of these normal anastomoses has been found dilated under circumstances of portal obstruction.

But besides these anastomoses with the venous portion of the portal vein, there are other branches joining its trunk, or arterial portion, first described by Sappey,|| under the name of 'accessory portal veins,' which, arising in the stomach, the gall-bladder, the lower surface of the diaphragm, or the abdominal parietes above the umbilicus, go to the liver, and are distributed in its substance with the portal veins.

The accessory portal veins which proceed from the abdominal parietes will throw light on the case before us. In fact, those arising from the diaphragm and abdominal wall run between the layers of the suspensory ligament of the liver to terminate in the left branch of the vena portæ, near the termination of the umbilical vein—thus establishing a communication between the arterial part of the vena portæ and the phrenic veins on the one hand, and the superior and inferior epigastric and cutaneous veins of the abdomen on the other. In the normal condition, they will be found in various numbers, anastomosing freely together and running along with the round ligament. If not injected, they are so fine as to be hardly visible; but when the arterial portion of the vena portæ is obstructed, they are the first to yield to the obstacle and become dilated.

The large anomalous veins which in the present case established the communication between the portal and systemic veins were obviously nothing more than an enormous development of these normal veins, as was found by their course corresponding in every particular to that of the accessory portal veins from the upper abdominal parietes, their upper part being surrounded by the liver-substance and terminating above in two large trunks, distributed exactly like the vena portæ, and these emerging from the liver in a large vein running in the suspensory ligament, with a large branch to the diaphragm, forming an anastomosis with the vena cava, while the great bulk of the blood poured itself into the right epigastric, which had thus acquired an enormous volume. Thus the singular anomaly, observed in the case related, is traced back to the point of normal anatomy first described by Sappey, whose observations, indeed, were called forth by some cases of cirrhosis of the liver, which had come under examination about that time.

It is true that these examinations are not all of equal value, nor entirely free from ambiguity, and in some of them the condition of the liver is passed over without notice. Still, in order to complete the subject, a synoptical table is added to the paper, referring to sixteen cases in which communications between the vena portæ and the iliac veins have been traced. Five of these belong to Sappey, and three to Bamberger, and in all these the liver was cirrhotic, except in one of Bamberger's, where the obstruction was caused by thrombosis of the vena portæ.

In observations on these cases, the author is dis-

posed to admit one of them, and only one,* as an instance of anatomical anomaly, representing, as he believes, an arrest of the abdominal circulation at a stage corresponding to its condition in batrachians, saurians, and some of the cetaceans.

This point is elaborated in the rest of the paper, and a few remarks are made as to the diagnostic and clinical value of such dilatations of the accessory portal veins. Finally, the paper is illustrated by two very carefully lithographed diagrams.

T. HOLMES.

NOTHNAGEL ON THE FUNCTION OF THE BRAIN.
The results of the previous experiments of Dr. Nothnagel have already been noticed in the LONDON MEDICAL RECORD (December 24, 1873). He has continued his researches on rabbits, and used the method of injection with chromic acid (Virchow's *Archiv*, vol. lx.). When only one lenticular body (nucleus lenticularis) was operated on, the results were the following. There were deviation of the leg of the opposite side (right) towards the middle line, and that of the same side (left) outwards; a lateral curvature of the spine with the convexity turned towards the opposite side (right), and at the same time a moderate cyphosis. The animal could, however, execute all voluntary movements. A different state of things occurred when both nuclei lenticulares were operated on. In twenty-six cases the author succeeded with the operation, and the results in all the cases coincided. Many results were negative, when the chromic acid focus did not lie exactly in both nuclei lenticulares. The introduction of a fine cannula and injection of chromic acid into the nucleus lenticularis were not followed by any phenomena of stimulation; the animal remained quite as quiet as if nothing had happened. When the bilateral injection was successfully executed and the animal was placed on the ground, it remained sitting and quite motionless, and when it was not disturbed, it remained in this condition for hours together. The animal did not make the least attempt at voluntary movements, and had a stupid and sleepy appearance. The spinal column was sometimes straight, sometimes cyphot, but never curved laterally. The ears were erect, and never laid backwards upon the neck. The respiration and action of the heart were normal.

If the fore limbs were carefully extended so that the animal did not lose its equilibrium, and though the feet might be placed in a very unnatural and awkward position, as over the neck, they were not drawn back, as always occurs in the normal animal. Slight pinching of the tail, which a normal animal would not notice, was followed by withdrawal of the feet from the unnatural position, and the animal appeared as if it would spring; but with one spring the movement came to an end, and the animal became motionless as before. The same thing could be repeated over and over again. A brilliant light held before the eye caused the pupil to contract, and the eyelids to close, but the animal remained motionless. In four or five cases, pinching of the tail was followed by the animal springing four, six, or even twelve or sixteen times. The animal sat without making any attempt at spontaneous movement; and remained motionless for hours, and, if not disturbed, until death occurred. It presented the well-known ap-

pearance of an animal from which the cerebral hemisphere had been removed. Further, the animals so operated on never ate of their own accord. Evacuation of the urine seemed to be rendered more difficult. Most of the animals died on the second or third day, but six lived till the seventh day, and were then very emaciated. The *post mortem* examination showed a circumscribed chromic acid focus of the size of a lentil in each nucleus lenticularis. When the focus was of this size, and was situated in the middle and extended towards the middle line and posterior part of the nucleus, then the characteristic symptoms were produced. If, however, the one nucleus were less affected than the other, or if the chromic acid had not affected the nucleus sufficiently in its depth, then the characteristic symptoms were not exhibited.

The author has already described the springing movements produced by injury of a distinct spot in the corpus striatum, called by him 'nodus cursorius.' When both nuclei lenticulares were operated on, and then the nodus cursorius was irritated by puncture with a fine needle, the springing of the animal from the table could still be produced. The animal commenced of itself to spring (when the nuclei lenticulares had been properly injured) from half a minute to two minutes after puncture of the nodus cursorius, and continued to spring until it met with an obstacle; when it again sat motionless, with its limbs in the same position as in the moment of bounding. The animal which had the nuclei lenticulares intact, when it met with an obstacle, commenced again to spring, without any new stimulation being applied to it.

In a third series of experiments, the author operated on both corpora striata. It was difficult to reach these organs and destroy them totally. The injection method could not be employed, for the fluid found its way to the fourth ventricle and caused the death of the animal. Their destruction was therefore effected by introducing, through a hole in the skull, a fine needle, and breaking them up. The symptoms which followed differed entirely from those produced by injury of the nuclei lenticulares. The most common effect was the following. When the point of the needle entered the ganglia the animal sat quite still. In a time, varying from a quarter of a minute to two minutes, the animal sprang about violently, to one side and to the other, avoiding obstacles in its path. The sensibility of the ocular and auditory nerves seems to be more increased than that of the cutaneous nerves. This increased sensibility remained in a diminishing degree for a few hours, at the very longest two days. The animals could execute voluntary movements. In a few days, scarcely anything pathological was to be observed.

The explanation given by the author of the symptoms produced by injury to the nuclei lenticulares is, that by extirpation of these organs the collective nerve-channels which conduct the motor voluntary impulses from their place of origin, the hemispheres, to the channels lying more posteriorly and peripherally, are interrupted. According to Meynert's expression, the collective 'psychomotor' paths are divided.

Regarding the experiments on the corpora striata, the author is of opinion, and he expresses this opinion with all reserve and as hypothetical, that the nucleus caudatus stands in relation to all those combined forms of movement which are excited by a psychical process, but then continue automatically without any

new voluntary impulse. Such a movement is seen in the play of the facial nerve in laughing, where the laughing lasts for a time, after the psychical process, which originally excited it, is already extinguished. The same is the case with running.

WM. STIRLING, D.Sc., M.B.

KOROWIN ON THE FERMENTATIVE ACTION OF THE PANCREATIC JUICE AND OF THE PAROTID GLAND ON STARCH IN NEW-BORN INFANTS.—Dr. Korowin (*Central. Bull.* 1873, p. 271-305) obtained the following results.^a The pancreatic juice during the first month of life had absolutely no power of converting starch into sugar. In the second month the action was very slight, and by the end of the third month the action was so strong that a quantitative analysis was in some cases possible. Towards the end of the first year it had arrived at its full power. The secretion of the parotid gland, on the other hand, changed on the first day of life a starch enema into sugar, and quantitative analysis could be made. The stronger and bigger the child, the more powerful was this property. The saliva could be collected from a child's mouth the moment of birth, but no great amount could be obtained until the end of the first month. By the end of six weeks any amount could be collected. He compared the saliva of a child at eleven months with that of a full grown person, and found that the amount of sugar formed was the same in each.

W. C. GRIGG, M.D.

LAHS ON THE CAUSE OF THE FIRST INSPIRATORY ACT IN INFANTS.—H. Lahs (*Archiv Gynakol.* iv. 1873) endeavours to controvert the opinion of Schwartz—the want of oxygen through the arrest of the placental circulation—by showing that a child may remain without breathing from ten to fifteen minutes after its stoppage; and the theory of Schultze—irritation of the skin—by proving that a child may still breathe whilst in the maternal passages. He believes that the act of inspiration arises from the sudden diminution of the placental space, and from the placental blood in the umbilical veins being dammed up against the child's heart, causing a pause during the diastole, thereby increasing the amount of circulation in the lung; which, either singly or together, produce inspiration.

W. C. GRIGG, M.D.

COLIN ON THE ACTION OF THE HEART.—At a recent sitting of the Parisian Academy of Medicine, M. Colin (*Progrès Médicale*, April 25) sought to demonstrate, with the aid of anatomical preparations, that in man and the higher animals, the auricular systole precedes the ventricular in the action of the heart, just as it occurs in the lower animals. He asserted that conviction of this fact may be obtained by taking certain precautions in experimenting on the higher animals. If the animal be carefully bled, to avoid disturbance of the cardiac circulation, and if artificial respiration be properly kept up, it will be clearly seen that the contraction of the heart begins at the auricles. The speaker undertook to perform and show the experiment whenever wished to do so.

M. Bouillaud opposed M. Colin's theory. He passed in review all the researches which had been made since the time of Harvey, and cited specially those of Beau and of Haller; all had arrived at the indisputable and well-established conclusion that, in man and the higher animals, the contraction of the heart commences at the ventricles; consequently the ventricular systole precedes the auricular.

SURGERY.

WATSON ON EXCISION OF THE ANTERIOR TARSUS AND BASE OF THE METATARSUS.—Dr. P. H. Watson, Senior Surgeon to the Edinburgh Royal Infirmary, describes this operation in the *Edinburgh Monthly Journal*, May, 1874. The subject of the operation had suffered for some time from subacute disease, evidently confined between the base of the metatarsus in front, and the astragalus and os calcis behind. Conservative treatment had failed to cure the patient; and as amputation of the foot appeared not to be justifiable in the then condition of the parts, Dr. Watson determined to excise that part of the skeleton of the foot which is bounded by Chopart's line of amputation behind, and Hey's in front; in other words, to remove the scaphoid, cuboid, and cuneiform bones, with the bases of the metatarsal bones. Although in this way all the disease might be removed, the question remained whether the parts thus left would consolidate soundly, or whether the reconstructed foot would be either seemly or useful. Dr. Watson found but little encouragement from the appearances presented by a tentative operation upon the dead subject; nevertheless, the experience of many cases of partial excision of the bones of the foot inclined him to hope for a better result for the excision of the tarsus in the living patient, than the appearances in the cadaver seemed to suggest. He believed, also, that the preservation of the plantar fascia, and of the tendinous structures in the sole of the foot, would largely obviate the rotatory tendency observed in the astragalus and os calcis after Chopart's operation. The risk of a return of the disease in these two bones, simply because they constituted a portion of the tarsus in which the disease had originally commenced, Dr. Watson looks upon as a speculative objection, whose untrustworthy character has been established by the good results of excision of single bones of the tarsus in the hands of many surgeons.

In order to perform the operation, incisions were made on the outer and inner sides of the foot, between three and four inches in length; that on the outer side extended from the centre of the plantar margin of the os calcis as far as the middle of the metatarsal bone of the little toe; that on the inner side, from the neck of the astragalus to the middle of the metatarsal bone of the great toe. The soft parts were then carefully dissected off the dorsal and plantar surfaces of the tarsus, from the outer and inner wounds. With a probe-pointed bistoury carried across the line of the articulation, first upon the dorsal and then upon the plantar surface, a separation was effected between the bones in Chopart's line. Then the shafts of the metatarsal bones were divided from below upwards with a key-hole saw; one handle of a pair of bone-forceps being inserted between the bones and dorsal soft parts, to protect the latter from injury. The large gap was now firmly filled with pads of lint; the dressing was left for forty-eight hours, and then fresh applied. This mode of dressing was continued for six weeks, and then superficial dressings were applied. Support was given externally by lateral splints of gutta-percha, and at a later period of treatment the arch of the foot was preserved by means of a suitably shaped gutta-percha pad. Six months after the operation the patient walked smartly and well; and quite recently, after an interval of nearly four years,

he walked almost without defect. Dr. Watson has since operated in an exactly similar manner in five other cases; in only one of the six cases had he to resort to further operative interference. This was in a very debilitated subject; the system of dressing the whole cavity of the wound was not carried out; the lines of incision closed, the matter began to bag in the deep parts of the wound, and amputation at the ankle-joint was resorted to; but nothing was afterwards discovered which would have prevented sound cicatrization, had the proper mode of treatment been carried out.

[The Reporter looks upon Dr. Watson's new operation as furnishing a very valuable contribution to the surgery of the foot. It is valuable not only in itself, but for showing how unnecessary it is to sacrifice the entire foot even for extensive tarsal disease. Dr. Watson in a recent case excised all the tarsal bones, except the os calcis, together with the ends of the tibia and fibula. At the time when he spoke, the patient was doing well.—*Rep.*]

WILLIAM MAC CORMAC.

FLAGG ON THE ACTION OF CHEMICAL SUBSTANCES ON THE TEETH.—Dr. J. Foster Flagg (*Dental Cosmos*, April, 1874) directs attention to the difference between the ordinary chemical action of acids upon such salts and organic tissue as compose tooth-structure, and that action which results in caries. Frequent and long-continued experimentation has failed, in almost every instance, to produce any result which could be considered as analogous to caries; and when, in isolated instances, teeth have been subjected to influences, either accidentally or designedly, which have proved adequate to the induction of a semblance of this disease, it has been found that either the concomitant of galvanism in some form might easily be indicated, or that microscopic research has proved the existence of such pathological conditions structurally as would indicate decided local predisposition to decay, if even the incipency of actual caries had not been announced by decided 'tubular consolidation.' This latter has been invariably found in the comparatively limited number of examinations of this condition which he has been able to make.

In connection with all the various published results of experiments as to the effect upon teeth of an extended list of so-called injurious articles, embracing the many acids which are in daily use, such as acetic, citric, tartaric, malic, lactic, etc., together with sugar, meats, etc., we remark only the effects noted, day after day, of enamel so altered in appearance as to have lost its brilliancy, or at length so altered in structure as to be easily scraped away with the finger-nail, or again, of dentine and cementum so softened as to be cut or even bent; and yet no particular mention is made of the fact that these results were unlike caries in every particular.

Dr. Flagg has found repeatedly the most beneficial effects produced by the administration of medicines which, used locally in the seemingly accepted method of experiment, would be disastrous in the extreme; for example, nitro-muriatic acid will be recognised as eminently destructive of tooth-tissue. He has not seen a case of dental caries which he could attribute to the use of any acid medicine, while he has again and again seen remarkably prompt cessation of dental tenderness and tendency to caries, resulting from local weakness of tooth-structure consequent upon long-continued biliary difficulty, from

the administration of fifteen to twenty drops of nitro-muriatic acid daily.

It has for many years been accepted by observant dental practitioners that teeth are injured, to a certain extent, by the long-continued use of acid medicines; but it has also been noticed that the injury is general, that enamel suffers most of all dental tissues, that it loses its brilliancy and density of structure. The injury is not, he says, prevented by taking the medicine through a glass tube. He has taught that such injurious action as was liable to ensue from acid medicaments should be prevented by rinsing the mouth thoroughly, immediately after swallowing the medicine, with water, to which had been added a few drops of solution of ammonia, or a small quantity of bicarbonate of soda.

Solutions of alum are injurious in a general way only; acting more or less severely, according to frequency and continuance of applications and strength of the solutions; these roughen and soften the enamel, and necessarily accelerate the progress of decay in already formed cavities, but never seem to cause decay of the teeth in the circumscribed and localised manner which pertains to dental caries.

APPLIED PHARMACY.

UMNEY ON THE PREPARATION OF PEPSIN.—

Mr. Umney, in commenting (*Pharmaceutical Journal*, April 4, p. 792) upon the pepsin now made official in the Addition to the *Pharmacopœia*, says that it is imperative that the directions as to washing be strictly adhered to; and profiting by a failure he experienced, he would say that the scraping even of the stomach is a matter of importance. A material point seems to be the sufficiently light scraping, in order that the fatty matter be not removed with the viscid pulp.

WAYNE ON THE LEAVES OF THE CASTOR-OIL PLANT.—Having noticed a crystalline deposit embedded in the chlorophyll that separated during the preparation of a fluid extract of the leaves of *Ricinus communis*, which is used by some physicians in the United States as a galactagogue agent, Professor Wayne removed a portion for examination, and found the crystals to be nitrate of potassium (*American Journal of Pharmacy*, March, p. 97). This would appear to be evidence that the salt exists as such in the leaves of the plant—a supposition that is confirmed by the fact that the leaves and stems burn with scintillation and decrepitation almost like nitre paper. Pursuing the subject, he submitted the leaves to a careful analysis for the presence of a proximate principle. The analysis failed to show the presence of any substance having the properties of an alkaloid, but proved that they did contain a proximate principle crystallising in square prisms and tables. This was obtained by percolating the leaves with dilute alcohol, driving off the alcohol in a water-bath, to separate the chlorophyll and resin, and filtering. The tannic acid and much of the colouring matter were removed from the filtrate by repeated shakings with moist hydrated oxide of lead; the solution was then filtered, and evaporated to a syrupy existence. This extract was exhausted with alcohol, and the alcoholic solution, upon evaporating spontaneously, yielded a pale yellow crystalline substance that, upon being redissolved in alcohol and

treated with animal charcoal, formed, upon a fresh evaporation, colourless crystals, prismatic and tabular in form. Submitted to suitable tests, they were found to be identical with the substance obtained by Professor Tuson from castor-oil seeds, and named by him 'ricinin.' Experiment led Professor Wayne to conclude that ricinin has no claim to be considered an alkaloid, as it has no action upon litmus paper, and is not precipitated by iodohydrargyrate of potassium. Yet it contains nitrogen, as is shown by the evolution of ammonia when it is heated with potash. It is soluble in alcohol and water, and has a bitter taste, resembling that of wild cherry bark. The portion of the extract insoluble in alcohol was tested for glucose, but none was found.

Analysis showed that this peculiar proximate principle exists in all parts of the plant; also, that the leaves are very rich in nitrate of potash, and in alkalies and phosphoric acid. 500 grains of the leaves yielded 120 grains of ash, which was found to have the following percentage composition.

| | |
|------------------|-------|
| Lime | 33.40 |
| Magnesia | 6.20 |
| Potash | 27.15 |
| Soda | 2.12 |
| Peroxide of iron | .70 |
| Phosphoric acid | 6.68 |
| Sulphuric acid | 2.90 |
| Chlorine | 1.63 |
| Carbonic acid | 16.20 |
| Silica and sand | 2.41 |
| Loss | .61 |

100.00

WELLBORN ON AN ADULTERATION OF PUTTY POWDER.—Mr. G. Wellborn states (*Pharmaceutical Journal*, March 1, p. 750) that having been led to suspect an adulteration in a sample of oxide of tin (putty powder), he analysed a portion of it, and found it to contain a considerable quantity of oxide of lead. Considering that oxide of lead, from its comparatively low price, might be a frequent adulterant of oxide of tin, he obtained samples from two other sources, and submitted 20 grains of each to analysis. The quantity of oxide of tin was the same in the three samples, namely, 5 grains; the remainder being made up with oxide of lead.

MARTINDALE ON CHLOROMERCURATE OF MORPHIA.—At a recent meeting of the Pharmaceutical Society (*Pharmaceutical Journal*, April 11, p. 809), Mr. Martindale mentioned a difficulty that he had met with in dispensing a solution for hypodermic injection, consisting of hydrargyri bichloridi gr. viij, morphiae hydrochloratis gr. iv, aquæ destillatæ 3j. The two salts were added to a little water in a test-tube, and dissolved by the aid of heat. On filtering and cooling, although more than four times the quantity of water was ordered that would have been necessary to hold either salt in solution separately, there was a large deposit of silky acicular crystals, due to the formation of a double salt of mercury and morphia. This is described by Watts as the chloromercurate of morphia, and has the composition represented in the formula—

There are nearly corresponding iodo- and bromo-compounds of mercury and morphia. With the prescriber's consent, a mixture of seven parts of water with five of glycerine was substituted, but even out of this the salt crystallised in a few days.

The solution had originally been ordered by Mr. Berkeley Hill, for the purpose of trying whether the

addition of morphia would lessen the pain and inconvenience which attends the subcutaneous injection of an ordinary solution of perchloride of mercury. This, however, was found not to be the case. In its place, therefore, was prepared a solution of the chloro-albuminate of mercury, from the formula of Mr. Staub (LONDON MEDICAL RECORD, vol. i. p. 278), but more concentrated. In this solution, excess of chloride of sodium and chloride of ammonium are dissolved with the perchloride of mercury, and added to a mixture of white of egg and water, the alkaline chlorides being said to prevent the combination of the mercury salt with the albumen. After a time, however, the solution became curdy—possibly because of its concentration—and Mr. Hill left off using it; but he informed Mr. Martindale that it caused less pain, and entered more rapidly into the circulation than the simple solution of perchloride of mercury. Mr. Hill's notes on the use of the two solutions are appended to the original paper.

HOLMES ON KOEGOED, A HOTTENTOT DRUG.—At a meeting of the British Pharmaceutical Conference at Brighton, Mr. Keyworth brought forward a vegetable substance named koegoed (literally cow-good), an infusion of which is administered by the Hottentots to cattle, and taken by themselves, when suffering from inflammation of the bowels through drinking brackish water. This substance has been identified by Mr. E. M. Holmes (*Pharm. Journ.*, April 11, 810) as the roots and procumbent stems of *Mesembryanthemum tortuosum*, a plant belonging to the natural order Ficoideæ. Besides being used as above stated it is chewed by the Hottentots as an intoxicating agent, and appears to possess narcotic properties which deserve further investigation.

Three other species of *Mesembryanthemum* are used medicinally by the Hottentots; but these have leaves of a different shape from those of koegoed, which are oblong-ovate, those of *M. acinaciforme* and *M. edule* being scimitar-shaped, and those of *M. crystallinum*—well known in this country as the ice-plant—being broadly ovate and amplexicaul. The expressed juice of the first two of the above mentioned species is used extensively in South Africa in dysentery, as a gargle in malignant sore throat, and as a lotion for burns and scalds.

HOLMES ON A SPURIOUS CASCARILLA.—Some cascarilla has recently been imported from Nassau, in the Bahama Islands, containing an admixture of spurious bark. This false cascarilla has been examined and described by Mr. Holmes (*Pharm. Journ.*, April 11, p. 810). At first sight it strongly resembles cascarilla; but the periderm or outer layer of bark does not readily peel off, and is of a fawn colour, not white. On the inner surface the bark is of a reddish tint, and is furnished with a number of straight, closely packed raised lines, which give it a striated appearance, the inner surface of cascarilla being smooth. The taste is not aromatic, but astringent, and almost without bitterness. The colour is also of a more reddish tint than that of cascarilla. It yields an infusion and tincture darker in colour than those of cascarilla. Treated with tincture of galls, the tincture becomes slightly cloudy, and with tincture of perchloride of iron it becomes almost black; but tincture of cascarilla is not altered in appearance by either of these reagents.

From the general appearance and microscopical structure of the bark, it seems probable that it may

belong to a plant of the same genus as the cascarilla, and Mr. Holmes is inclined to attribute it to *Croton lucidum*, L. The bark of this plant is said to be used by the negroes of New Providence to mix with true cascarilla bark, under the idea that it improves the curative powers of the latter. It is known by the name of 'false sweetwood bark,' sweetwood being the name applied by them to the true cascarilla.

HOLMES ON AN ADULTERATION OF ARNICA ROOT.—Mr. Holmes reports (*Pharm. Journ.*, April 11, p. 810) that he has recently examined two samples of 'arnica root' received from Germany, one of which contained only 50 per cent. of the genuine root, and the other only 10 per cent. In both samples there were two or three kinds of roots; but the chief adulterant in both cases was identified as the root of *Geum urbanum*, an indigenous plant well known to herbalists in this country under the name of Avens, or Herb Bennet. The spurious drug may be at once recognised by the fact that it is not a rhizome, or prostrate stem, like arnica, but a root which evidently descends vertically into the soil, as it is surrounded on all sides by rootlets. In size it varies from that of arnica to five or six times as large, in some pieces appearing præmorse, and in others suddenly narrowed and elongated. The cortical portion resembles that of arnica in colour, but the medullium, or central portion, is of a purple tint, and presents a discoid appearance, two characters met with in but few roots. When the root is soaked in water the purplish medullium swells up and loses its discoid appearance. The odour of arnica is distinctive, and the taste has a peculiar acidity, and an after flavour which may be likened to the odour of rancid coconut oil, whilst the taste of *Geum urbanum* is astringent and somewhat aromatic, faintly resembling that of cloves.

HOLMES ON AN ADULTERATION OF BELLADONNA ROOT.—A sample of belladonna root imported from Germany has been found by Mr. Holmes (*Pharm. Journ.*, April 11, p. 811) to contain 50 per cent. of a malvaceous root, which he believes to be that of *Malva sylvestris*. The adulteration is an important one, as it would in this proportion reduce the strength of belladonna preparations one-half; but it is easily detected. Externally the two roots are very much alike, especially when the belladonna is in small pieces; but internally the structure and appearance are very different, belladonna having a very large medullium and small cortical portion, while in the mallow the two are nearly equal. Also the fracture of belladonna is short, while in the mallow it is distinctly fibrous.

B. H. PAUL, Ph.D.

OPHTHALMOLOGY AND OTOLOGY.

WARLOMONT ON A MODIFICATION OF A TREPHINE FOR THE CORNEA, OR FOR USE AS AN ARTIFICIAL LEECH.—Dr. Warlomont (*Annales d'Oculistique*, July and August, 1873) says that trephining the eyeball, so called by Wecker (*Annales d'Oculistique*, 1873, vol. lxi.), is an operation by which he removes a circular portion of the cornea in cases of partial or complete staphyloma, in order, by the gradual formation of connective tissue, to reduce

its curvature, or to establish a corneal fistula in cases of complete leucoma. Mr. Bowman has carried out the same idea with a view of lessening the cone in conical cornea, his trephine consisting of a series of cylinders of the size of goose-quills, with cutting edges. The instrument is rotated by the thumb and finger, and the small circle of cornea is removed by the forceps.

Though admitting that M. Wecker's instrument and that of Mr. Bowman both answer their purpose, M. Warlomont considers that of M. Wecker to be too complicated and far too costly; hence his suggestion of what he considers a more simple instrument, which consists of a circular blade rotated by a spring, easily worked by the pressure of the finger upon a button at the upper extremity.

M. Warlomont believes that this simple instrument may take the place now occupied by the various kinds of artificial leech.

CRITCHETT ON THE TREATMENT OF CATARACT PREVIOUSLY TO OPERATION.—In the *Annales d'Oculistique* (Sept. and Oct., 1873) are some valuable notes on the question, one not very fully treated of in standard works: Is it the duty of the surgeon to warn his patient of the nature of the disease when it has but barely commenced, and when a long and anxious time must elapse before any operation can be attempted? Mr. Critchett, even at the risk of appearing to overlook the true nature of the case, would be reticent, knowing how the thought of impending blindness from cataract is dreaded.

Another question which has to be met is, whether there is any cure, any means of removal by medicine or otherwise, short of an operation. It is at this time that patients with cataracts are apt to fall into the power of quacks and charlatans. Though the answer to this question must be a decided negative, yet there is much that may be done to relieve the present discomfort; for instance, the amount of light may be regulated by the employment of proper glasses, and by the continued use of atropine in solution. It will be well too that the patient should be seen at regular intervals, in case the commencing cataract may be the precursor of some more serious condition, such as glaucoma; and by degrees the knowledge that the increasing dimness of vision is due to cataract and to nothing worse, may in itself be a reason for looking hopefully to the future.

The time for operative interference has arrived when—

1. The cataract is completely matured;
2. The lens of the second eye is also so opaque that the patient is on the point of having to relinquish his occupation.

The social position of the patient must be borne in mind; but the second condition is to be insisted upon, because surgeons of the old school used to delay till blindness was complete, and there is a tendency amongst some surgeons of the present day to adopt the other extreme and to attack every single cataract at once.

There are some cases of cataract which will, Mr. Critchett thinks, always give rise to difference of opinion, and which indeed are embarrassing; viz., when there is very great impairment of vision while the cataract is yet far from maturity. Is the surgeon to operate upon an immature lens? or is he to hasten the maturity by some operation? The latter course Mr. Critchett believes to be full of danger; and, except in cases where the cortical layers

of the lens are much involved it is, he thinks, the duty of the surgeon and in the patient's interest to wait. In the cases where one is cataractous and the other quite sound, Mr. Critchett thinks that in young subjects it is well to operate, but in elderly patients, while one eye retains its perfect power, the cataract in the other should not be interfered with.

BOWATER J. VERNON.

PIERMÉ ON PROLAPSE OF THE VITREOUS HUMOUR.—*Le Mouvement Médical* contains a review of a work on this subject, which is a most interesting and important one for all who have to perform any of the operations for cataract. In the days when the old operation by flap was in vogue, and even in later times when as yet von Gräfe's method of extraction had not been modified as regards its line of section, prolapse and loss of vitreous humour was a very common occurrence. Now that the section is no longer made in such dangerous proximity to the zonula, its occurrence has become more rare, but is none the less of very serious moment.

On the anatomical changes which take place immediately after loss of vitreous humour, and on the question of its redevelopment, authorities give but very little information. M. Pierné has studied the subject by the light of physiological experiments upon animals, as well as from its clinical and surgical aspect, and his results are embodied in four chapters. The first chapter is devoted to the normal anatomy of the vitreous humour. The second gives an account of his experiments performed upon rabbits. The third is devoted to clinical observations; and, in the fourth, are summed up the conclusions derived from the preceding three.

The chapter on the anatomy of the vitreous body apparently calls for no remark on the part of the reviewer, except one of regret, that nearly all the information which could be obtained had been drawn from the labours of foreigners.

The results of the experiments made upon the eyes of rabbits showed that, when a small quantity of the vitreous humour had been removed by means of a small syringe, the operation was a very simple one, and was attended by no evil consequences, no hæmorrhage, nor any inflammation of the coats of the eye. Thirteen such experiments are recorded, and in all, the eye which was soft and somewhat shrunken after the operation, in a few hours had regained its normal tension and appearance. The author asks whether, in these cases, the vitreous humour reproduced is identically the same, or, merely a new substance, more or less resembling that which had been lost; and he feels inclined to admit the reproduction of a veritable vitreous humour, and for the reason that the fluid removed from the vitreous chamber is the structureless and albuminous fluid which is again speedily reproduced from the surrounding blood-vessels. M. Pierné even admits a renewal to a certain amount of the nucleated cells described by Iwanoff. Surgical experience shows that a man may lose vitreous humour in consequence of a wound of the sclerotic, and in a short time the eye may regain its normal appearance and may retain its sight; and it has been the experience at some time or other of most surgeons, that on the day following a cataract operation, during which vitreous humour has been lost, the tension of the eye has been completely restored. It is, however, probable, that such eyes are never so sound or so well able to withstand disease, as those which have passed

through the operation without accident. The case is far otherwise, however, when the loss of vitreous humour has been considerable; there is then the risk of choroidal or retinal hæmorrhage, with detachment of the retina perhaps, or, in the instance of a cataract extraction, the fragments of the cortical substance which are retained in the eye may become the exciting cause of proliferative changes, and take the shape of suppuration, or of membranous opacities which must prevent useful vision.

The conclusions arrived at by M. Pierné are as follows.

1. The vitreous humour is reformed readily and speedily both in the eyes of man and of the lower animals.

2. Prolapse of the vitreous humour is of greater danger when the wound is large, and naturally the gravity of the accident is greater in proportion to the amount of the loss.

3. The vitreous humour may become the seat of an inflammation in consequence of a wound, and this inflammation may terminate by resolution, by suppuration, or may become chronic.

4. The immediate evil consequences of prolapse, generally have their origin in the choroid; and the ultimate result is atrophy of the eyeball.

BOWATER J. VERNON.

ROBERTSON ON A CORNEAL WART.—Dr. C. A. Robertson relates the following case in the *Philadelphia Medical Times* for February 28.

The patient, named James Taylor, about seventy years old, had had for several years a dermoid growth, which started on the outer and lower part of the right eyeball, and early showed a tendency to intrude upon the transparent cornea. At an early period of the complaint Dr. Robertson attempted to destroy the wart, by cutting off its surface and applying chromic acid. This treatment not proving successful, or for some other cause, he ceased his visits, and Dr. Robertson lost sight of him entirely until he presented himself at St. Peter's Hospital in Albany, in October last.

In the meantime he had been told that the growth was dangerous, and that the only thing to be done was to remove the eyeball.

Upon examination, Dr. Robertson found that the wart, in its growth, entirely covered the cornea, except a very narrow tract at the upper inner margin. All sense of vision was obliterated. The wart was of a roundish form, and a whitish-gray colour. To the touch, it was soft and unctuous. In structure it was composed of papillæ, which were separable almost to the base; and near the lower edge these papillæ stood up in coarse filaments, or little crowded columns, almost a quarter of an inch high. From these, they were graduated down until they were nearly on a level with the cornea at the region of most recent invasion.

In order effectually to rid the patient of this wart, the eyelids were held apart with the ordinary silver-wire speculum, and then, with delicate scissors curved on the flat, all the coarser portions which it was practicable to cut were removed, leaving on the eye only the base of the structure as a raw surface. Then, taking a bent lance-shaped knife (*iridectome*), Dr. Robertson carefully insinuated its edges under the upper sessile border of the excrescence, and, by gentle manipulation, teased away the adventitious growth from its connection with the surface of the cornea. When the operation was terminated, the

colour of the iris and the black pupil were visible, and the patient remarked that he could see objects.

Very little reaction followed. The cornea steadily improved in clearness as the natural superficial or epithelial layer was reproduced, and within a very few weeks the sight became as good as in the other eye, in which it was perfect. Four months after the operation, there was no vestige of the old trouble to be seen, and the cure appeared to be perfect.

EPIDEMIOLOGY.

HALL ON SMALL-POX IN LEEDS.—Mr. F. Hall's report of the Leeds Small-Pox Hospital, for the year ending August 15, 1873, is very short, wholly to the point, and rich in evidence of the value of efficient vaccination. Mr. Hall treated during the year 155 cases, 130 of which were of persons under thirty years of age. Unlike many reporters, Mr. Hall notes the importance of *quality* in vaccination, and the results of his observations on this point are of great interest and importance. Of 71 well-vaccinated persons under his care not one died, whereas of 57 badly vaccinated persons eight died, and of 27 persons not vaccinated at all, 18 died. Mr. Hall recommends 'a systematic inspection by competent persons of public and private schools, to ascertain by the kind of scar visible, whether the operation has been effectually performed with the view of course of having it repeated when necessary.'

The substance of Mr. Hall's report is contained in the following tables, which we extract entire; remarking by the way, that we think it would have been an improvement, if the classification adopted in Table 5 had been also adopted in Table 4.

No. 4.—VACCINATION RETURNS.

| | No. | Death. | Per-centage. |
|--|-----|--------|--------------|
| With well-marked characteristic vaccination scars | 71 | — | — |
| Indistinct marks of vaccination . | 29 | 1 | 3'4 |
| Said to have been vaccinated, but no marks visible | 28 | 7 | 25'0 |
| Not vaccinated | 27 | 18 | 66'6 |

ALEX. COLLIE, M.D.

NEW INVENTIONS.

EXTRAIT DE VIANDE LIEBIG DE LA PLATA.

Since Baron Liebig first introduced beef-essence to the public as an accessible and useful article of food, there have been several candidates in the market basing their claims to favour on varieties in the mode of preparation and in advantages of certain localities, &c. The most recent of these are MM. Benite & Co., of Buenos Ayres, who introduce the 'Extrait de Viande de la Plata' with special recommendations of its purity, superior quality, and cheapness. We have not investigated the relative cheapness, but, in *quality*, this extract seems superior to those which we have been using. The best test is the one that is readiest. Take an equal weight ($\frac{3}{4}$) of this and of the better known extracts, and mix sufficient hot water to make three-quarters of a pint of soup with each; the 'La Plata' extract will be found, though of lighter colour, to be much more aromatic and to have less of the 'burnt' taste which has raised a formidable objection to the general adoption of these meat-extracts.

If, however, the condiments that are recommended in the 'Buenos Ayres' programme be added, viz.: plenty of salt, onions and carrots, or celery, and if the cook will only take the same trouble that she would with soup made from 'fresh' meat, such a savoury mess will be produced that even the most delicate appetite will be tempted, and at a cost not exceeding a penny a bowl. It has of late been the custom to decry extracts of meat, more especially in Sweden, where the fact of their minimum nutritive value has been insisted upon; but MM. Benite & Co. have taken the opinion of the most distinguished chemists at Kiel, Berlin, Pisa, Breslau, Hamburg, Brussels, &c., and these have certified that the extract in question is in all respects equal to the best-known extracts. After an extensive trial in hospital practice, we are persuaded that the values of extract of meat are great, and that the objections to it are largely imaginary. In the first place, it is cheap and handy, and does not require great skill or time in preparation; next, it is a good vehicle for bread, whilst at the same time affording warmth; and lastly, it is aromatic, and thereby stimulates the appetite to take other kinds of food. The objections on the other hand are fanciful; for to many minds the fact of its cheapness is one of its main drawbacks—a remark that applies equally to Australian beef and mutton—it is thought to be procured from an inferior kind of cattle, whereas the very opposite is really the case. To say that it has no nutritive power is to assert what is at any rate not proved, and is to go against the well-elaborated scientific deductions of the original proposer, and the experience of those who have to deal with the question of the satisfactory feeding of large bodies of people. The 'La Plata' extract yields a broth light in colour, fragrant and agreeable, free from the bitter taste which, it must be confessed, spoils some of the extracts that we have seen; and, if chemists may be trusted, is very nutritive in quality. The 'La Plata' extract was first introduced in 1869, and was extensively used by the 'Red Cross' Committee in the war of 1870-71, since which time its sale has been very extensive. As a basin of soup for lunch, the best way is to make a decoction of carrots, onions, celery, &c., in water, and at the time of serving,

add a small teaspoonful of the extract to each pint of fluid, taking care to put in plenty of salt; or the vegetables may be replaced by sago, vermicelli, tapioca, &c. The proprietors recommend that fresh bones, which cannot otherwise be utilised, be boiled with vegetables as above named, and a portion of 'extract' added, the result being eminently satisfactory. It is sold at all the principal grocers' shops and purveyors, in pots of various sizes, and each pot is verified by the signatures of MM. Depaire and Joret, professors at the University of Brussels and the Military School of Belgium. A kind of chocolate is also prepared from the extract, which is portable, and of great use to pedestrians, and especially to mountain-climbers.

Though firmly convinced from practical experience of the virtues of 'Beef-Extract,' and 'Canadian Pork,' it is almost in despair that we again ask the public to give them a fair trial, so dear to an Englishman is the sentiment (and what more is it?) of the 'Roast Beef of Old England.' A night journey in a Rotterdam steamer is enough to dispel all ideas of what is temptingly called 'prime English beef;' and when a company ensures—and it may be verified by any visitor—that it has the very best cattle, fed on pastures belonging to the establishment, and of large extent, and therefore able advantageously to offer an article which on the simplest principles of economy is seen to carry with it the credentials of purity and cheapness, why, in the name of common sense, do not the lower and middle classes at any rate, if not the upper, to whom lavish expenditure may be no object, economise their butcher's bills, and support a line of commerce whose resources are almost unlimited, and as yet only imperfectly developed?

T. CLAYE SHAW, M.D.

Dr. Alexander Collie, of the Metropolitan Asylum District, Fever Asylum, at Homerton, writes as follows: 'The extract of meat makes an excellent soup, superior in our opinion to the others, especially in flavour. It was very much liked by our patients, which was not the case with the other extracts which we have tried.'

Dr. J. Crichton Browne, of the West Riding Asylum, Wakefield, says: 'I have carefully examined the specimen of "Extrait de Viande de la Plata" forwarded to me, and have formed a very favourable opinion of its quality. It is of a dark brown colour, and has a pleasant aroma. Four drachms of it, mixed with fifteen ounces of boiling water, makes a strong beef-tea of agreeable odour and taste, darker in colour than that procured by mixing the same quantity of any other extract which I have seen with the same amount of water, and entirely free from any saltiness. Administered to invalids, this extract is taken without objection, and is said to be palatable. As far as I can judge from the use of a small quantity, it is fully as nourishing and supporting as Tooth's extract, which we have hitherto been in the habit of using in this hospital.'

FIELD'S PULMONIC CANDLES.

The medicated candles, introduced by Messrs. Field and Co., have been widely and favourably noticed. The notion of mingling benzoin, storax, and other balsams in the material of a well made candle, and thus diffusing medicated vapours through

a chamber, is a very ingenious and practical one. It admits, no doubt, of further development, and medical men will be able probably, by using the present form of candle, to devise or suggest to the makers other formulæ not less useful. The most obvious use of the medicated candles is, of course, for the aerial treatment of respiratory diseases.

MISCELLANY.

THE AUSTRIAN Minister of the Interior has sanctioned the establishment of a special department of Psychological Medicine in the General Hospital of Vienna.

THE HYGIENE OF INFANCY.—The Medico-Chirurgical Faculty of Parma proposes 'The Physical Hygiene special to Infancy' as the subject for the first competition for the biennial prize (a gold medal of the value of 12*l.*), founded by Professor Speranza.

A CONGRESS of Asylum Physicians of the South-west of Germany was held on the 2nd and 3rd instant at Hephenheim. It was attended by eighty-four members. Communications were read by Professors Eckhard of Giessen, Friedreich, Moos, and Erb of Heidelberg, and Drs. Emminghaus, Otto, Hirn, and Bandorf.

A LECTURE TO LADIES.—A very tragic occurrence took place recently at Bucharest. Dr. Bernath, the principal of a public laboratory in that city, was giving a popular lecture on chemistry. Among his hearers was a Madame Davila, a lady of good family and intimately acquainted with the professor. The lady was taken ill in the course of the lecture, and the doctor prepared a draught for her in which he intended to mix some quinine, but by accident used strychnine instead. The unfortunate victim was taken out into the street, and died almost instantly.

THE statistics of the special hospital of Suleimanie give the following figures for the years 1820 to 1864.

During this period, 673 insane patients were received in that establishment—532 males and 141 females. The Caucasian race was represented by 566; the Ethiopian by 81; the Mongolian, by 26; 116 patients could read and write; 50 could read only; and 501 were totally illiterate. In regard to etiology, religious fanaticism was considered to be the cause in 254 cases; 7 cases were attributed to a religious idea of another kind, which the author diagnoses under the denomination of religious scruples. The abuse of opium counted 20 victims; hasheesh, 94; alcoholic drinks, 88; domestic troubles, 127; disappointments of various kinds, 15; hereditary, 26; insolation, 61.

CHOLERA has appeared at Rzepisch (Upper Glogau) in Silesia. On the 2nd instant several persons were attacked.

THE Faculty of Medicine of the University of Kiev have decided on establishing a dispensary for accouchements and the diseases of women.

REGISTRATION OF DEATHS.—A good story illustrative of the necessity of some such officer as the Médecin Vêrificateur for this country was told to the Royal Sanitary Commission by Dr. Burke, Deputy Registrar-General of Ireland. He mentioned the case of a physician who, having been in attendance on a person showing symptoms of acute illness, was informed of his death as having occurred on the previous day. Calling, however, casually at the house next day, he was shown into a room where, to the confusion of all concerned, the dead man was discovered alive and hearty. A death-certificate is sometimes an article of great commercial value, and very extraordinary ruses are sometimes employed to obtain it. Nor is crime less subtle than fraud in its efforts to obtain the certificate which silences all questions and opens the door of the cemetery.

ANTIDOTE AGAINST RABIES.—Dr. Jitzky lately communicated a very interesting circumstance to the Imperial Society of Wilna, in Russia, respecting a very vicious dog, who had a habit of rending vipers (*Coleuber verus*) into pieces, and whose muzzle and neck were covered with tumours produced by the bites of these reptiles. This dog was bitten by a rabid dog, which had caused death from hydrophobia to several horned animals and a young dog. The owner of the first-mentioned dog, who valued it, kept it alive, but watched it continually, so as to destroy it on the first appearance of rabies. No symptom of the disease, however, appeared; and to the great astonishment of Dr. Jitzky and of its owner, the dog continued in perfect health. But what particularly attracted Dr. Jitzky's notice was, that a woman living in the same locality was first bitten by a viper, and subsequently by a mad dog, and hydrophobia did not ensue. This led him to ask if there were not an antagonism between the venom of the viper and that of rabies. If this be admitted, it would be possible to preserve young dogs from hydrophobia, by inoculating them with the venom of the viper. It is reserved for future experimentalists to decide the reason of the singular coincidence which occurred in the facts above cited. We also learn from the *Gazette le Kieulanine*, no. 38, 1874, that amongst the remedies vaunted against rabies, and which are about equally effectual, the 'znakhars,' a kind of wizards in the south of Russia, employ the root of the black turbit (*Euphorbia palustris*).

AMERICAN MEN AND ANIMALS.—Dr. Brown-Sequard in a recent lecture in New York, announces the curious fact that animals in America can bear an injury better than the same species in Europe. He goes on to say: 'I have ascertained that it is so for man also. And this is why many medical writers in Europe consider that facts of this kind published here are mere inventions. There is a distrust among European physicians, because the former cannot understand how man in this country can survive terrible injuries which would be fatal to him in Europe. I would not say that the truth is absolutely respected in this country or anywhere else, but still there is no doubt that the facts which have been mentioned are perfectly true. Experimenting on a rabbit before a class in the University of New York, I had announced to them that pushing the instrument, as I was about to do, along the cord, would be quite enough to kill the animal immediately. Fortunately for me, I had said that death was due to the hæmorrhage accompanying the instrument, and not to the lack of the influence of the spinal cord. After pushing the instrument in for some distance I found the rabbit which had been operated upon eating a carrot. The class laughed more than you do now, and not at the rabbit, but at me. I could not understand at first what it was due to, and I then pushed the bar of iron its full length, or nearly one half the extent of the spinal cord; but the rabbit continued to eat its carrot. Fortunately for me and for science, I found that there was no hæmorrhage at all. I then took up the rabbit by its ears and showed that there was no bleeding, and explained in that way the persistence of life. What I had said therefore was verified by the fact that in Europe death takes place by hæmorrhage. This tendency to hæmorrhage in European animals is one of the differences between the animals of the two countries, and there are other important differences.'

NEW YORK SOCIETY OF NEUROLOGY AND ELECTROLOGY.—A society has lately been incorporated in New York, entitled 'The New York Society of Neurology and Electrology;' for the study of the anatomy, physiology, pathology, and therapeutics of the nervous system, and of electricity in its relations to physics, physiology and therapeutics. The society is to hold its meetings on the third Monday evening of every month, excepting the months of July, August, and September, and there are to be six standing committees; viz. on the Anatomy and Histology of the Nervous System; on the Physiology and Pathology of the Nervous System; on the Thera-

peutics of the Nervous System; on Psychology; on Electro-Physics and Electro-Physiology; and on Electro-Therapeutics. All papers, communications, cases, preparations, and apparatus, pertaining to their respective subjects are to be referred to these committees; and each committee is to make one annual report of the progress of its respective subject. The officers of the society for the current year are:—President, Dr. Meredith Clymer; Vice-President, Dr. Austin Flint; Recording Secretary and Treasurer, Dr. Carroll; Corresponding Secretary, Dr. Mason; Executive Council, Dr. Flint, Dr. Dalton, Dr. St. John Roosa, Dr. Loring, Dr. Beard. The society comprehends many corresponding members, amongst whom we note the names of Drs. Althaus, Anstie, Bastian, Claude Bernard, Crichton Browne, Bucknill, W. B. Carpenter, Lockhart Clarke, J. M. Charcot, E. Du Bois-Reymond, Duchenne de Boulogne, Sir Wm. Gull, Helmholtz, Hitzig, Hughlings Jackson, H. Maudsley, C. B. Radcliffe, Russell Reynolds, Schiff (Florence), Tripiet, Samuel Wilks, Virchow, Vulpian, and other eminent men.

MINERAL WATERS IN ALGERIA.—Among countries noted for their mineral waters, in respect of the number, variety, and hygienic properties of their springs, Algeria stands first. In most cases ruins in the immediate vicinity attest the fact of the old Romans having appreciated the curative qualities of the waters quite as much as the Arabs of the present day do. The principal of these springs are Amman Rhira, on the ruins of Aquæ Calide, famed in the time of the Roman emperors, the waters being very similar to those of Baden and Lucca; Hammam Meluan, about twenty-one miles from Algiers, the waters of which are highly saline as well as mineral, and are particularly efficacious in cases of rheumatism, gout, and skin diseases; the sulphurous springs of Hammam Berruagua, the temperature of which is about 81° Fahrenheit; the 'Queen Baths,' close to Oran, originally founded by Joanna, daughter of Isabella the Catholic (the grottoes adjoining the springs are in this case converted into *sudatoria* or hot rooms); and, lastly, the Hammam Meskutine (Aquæ Tibilitanæ), which are situated in the midst of a lovely entourage, and the waters of which attain a temperature of from 126° to 169°, and are peculiarly suited for the cure of diseases of the joints and skin affections.

ALLEGED REMEDIES FOR HYDROPHOBIA.—The asserted prevalence of hydrophobia at the present time is bringing forward the usual crop of nostrums for the cure of this hitherto incurable disease. Among them is one which is brought forward with more than the usual weight of evidence in its favour. Mr. Prince, of Tunbridge Wells gives in the *British Medical Journal*, the formula for a prophylactic against hydrophobia. In reference to this preparation he states that out of twenty persons who had been bitten by mad dogs, eighteen to whom he administered it felt no ill effects from the bite, whilst the remaining two who refused to take it died of hydrophobia. The same results, he alleges, occurred in the case of a number of cows and pigs who were bitten by a mad dog. Mr. Prince has purchased this formula, and very liberally places it at the service of the profession by publishing it in the *British Medical Journal*. The ingredients are as follows:—A small handful of tree-box, a small handful of toad-flax, three hands of foetid hellebore or setterwort, a small handful of primrose-roots. These are to be boiled in a quart of new milk down to a pint. The decoction is then to be strained, and, when cool, any skim is to be removed. The following are then to be added; Gascoigne powder, three drachms; and two drachms each of jalap and carbonate of iron. The handful each of box and toad-flax means that about three or four inches of the terminal branches, with the leaves on, of the box-tree, and as much of the stem of the toad-flax as possesses leaves and flowers are to be taken. This in weight of the dried herbs is, of box, one ounce, and of toad-flax six drachms. Three hands of the hellebore mean three entire leaves with the axil, which, when dried, weigh about two

scruples. The primrose roots are not essential, and have been omitted for some years. Mr. Prince suggests, however, that in place thereof the ground liverwort should be substituted. In a more tangible form, the formula should appear as follows.

R. Buxi sempervirentis 3j; antirrhini linariæ 5vj; hellebori foetidi 5ij; lichenis cinerei terrestris 3iij.

Powder the dry, or bruise the green, herbs in an iron mortar; put them into a quart of cold milk and boil down to a pint; strain while hot, skim when nearly cold, and then add pulv. Gascoigne 3iij; pulv. jalapæ, ferri carbon. sing. 5ij. M. One-third part of this mixture is to be taken on three consecutive mornings, fasting. The following directions are added: 'If working of them too much, make four of it for Christians, but for beasts three times as much. If the person is mad before taken in hand, mix the same quantity of powders as above in a teacup of new milk till a drink can be made. Bleed once or twice in two or three days after the drink is taken. If the sign be high, put in the same quantity of powders as above (in the drink); if low, not quite so much. Half of this draught is considered necessary for a child seven years old. If the wound be bad, apply a clove of garlick.' Hence, it appears to have been considered applicable even after symptoms of hydrophobia had commenced.

Of these ingredients box-tree and lichen can always be obtained; the toad-flax is not kept in store by herbalists, and, therefore, cannot be obtained in any quantity until the plant is again in flower. Gascoigne powder can be procured from any respectable chemist, and consists of certain proportions of crabs' claws, hartshorn shavings, and amber.

SMALL-POX AND VACCINATION.—A series of official documents have recently been published in Prussia on the epidemic of small-pox, which raged in that country during the years 1870–1872; and also on the question of vaccination. These documents likewise contain information regarding other countries, and are accompanied with tables; whence the following details are extracted. Out of a total mortality of 735,593 persons in Prussia during 1871, 59,839, or 8.13 per cent. died of small-pox. In 1870, 441 circles had been spared by the scourge, whilst in 1871 no more than two had escaped its ravages. In Berlin 6,478 persons died from small-pox from January 1, 1871, to July 1, 1872. According to the published tables, the number of mortal cases from small-pox before the introduction of vaccination, was from 8 to 20 per cent. of the general mortality; after the employment of the vaccine matter, the number was lowered to 0.5 per cent.; but in the recent epidemic it rose almost to the old level. In addition to the 59,838 deaths in Prussia in 1871 from small-pox there were more than 400,000 attacks of this malady. The report to which we refer insists on the necessity of vaccination, and even of compulsory revaccination. It also refers to the Transatlantic countries, and shows the ravages made by small-pox in China, India, &c. It is likewise pointed out that as Bombay has become the principal seaport of India since the opening of the Suez Canal, its sanitary condition is of special interest; for the health of all Europe depends more or less on that of that city. It therefore seems to be indispensable to pay great attention to the sanitary measures in force in the East, especially in Asia, so as to cause the adoption, if need be, of improvements calculated to be of general utility. The compiler of these documents is of opinion, on this point, that the use of vaccination ought to be made compulsory by international agreement.

ACTION OF PREPARATIONS OF IRON.—At a late meeting of the Therapeutical Society of Paris, M. Lebaigne laid before the meeting a paper on the mode of action of preparations of iron generally, and on dialysed iron in particular. A discussion ensued, in which M. Mialhe remarked that he had established the fact that all the salts of iron had the power of precipitating oxide of iron in the organism. When the acid of salt of iron is organic, it is oxidised; when it is mineral, it combines with the alkalis

of the blood. In both cases, the oxide of iron is brought out. M. Mialhe could not see any motive for particularising the oxide brought under notice at the expense of the others. All the compounds of iron which have the quality of precipitating their oxide into the blood are equally good; the phenomenon will take place with the chloride as well as with the sulphate of iron; and in this aspect all the compounds of iron will be equally successful. Doubtless all preparations are not equally useful in the hands of the physician; but the fact results from other reasons, rather physiological than chemical.

M. Delioux de Savignac did not consider that the remarks which had been read were sufficiently supported by facts in relation to elimination, and added that all the salts of iron are eliminated by all the passages, and especially by the urine. He had always discovered iron in that liquid. Entering on the question of preparation of iron, M. Delioux de Savignac said that he did not believe chlorosis was always cured by the administration of iron, however large might be the dose administered; but little remains in the blood, neither is it sufficient that the iron should remain in the blood; it must lodge in the globules, and it is further necessary that these should not diminish in number. It is, therefore, more a question of affording nourishment to the organism than supplying it with iron, and the ferruginous mineral waters with the small quantity of iron they contain, are often sufficient for this purpose. M. Bucquoy remarked that he thought the best preparation of iron was that which agreed best with the patient, whilst M. Constantin Paul avowed his opinion that all the physiological explanations that can be given about preparations of iron are pure hypotheses; since we have no knowledge as to the manner in which the iron introduced into the organism acts.—*Gazette Médicale de Paris*, April 25, 1874.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, MAY 27, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

GUBLER, COUTINHO, AND RABUTEAU ON JABORANDI, A POTENT SIALAGOGUE.

In November last, Dr. Coutinho, of Pernambuco, brought to M. Rabuteau some leaves of a shrub growing in Brazil, but of which the class has not yet been decided. It is known as jaborandi (*Piper jaborandi*), and a description of it will be found in the *Diccionario de Botanica brasileira*. M. Baillon, however, the well-known French botanist, is of opinion that the leaves received from Dr. Coutinho do not belong to a *Piperaceous* plant at all, but to one in the order *Rutaceæ*, which he identifies as *Pilocarpus pinnatus*, Linn. These leaves are of an elongated oval form unbroken, of an average length of from ten to twelve centimètres, and have a pinnated innervation. Dr. Coutinho asserted that they possessed sudorific properties, which he had found useful in his practice, and wished Dr. Rabuteau to make a chemical analysis of them. That chemist therefore proceeded to make an analysis of the small quantity of leaves in his possession, from which we reproduce the most important results. Not satisfied, however, with the chemical results he obtained, Dr. Rabuteau wished to try what would be the physiological effects, and taking a small quantity he had left in his possession, he has embodied the results of his experiments with the chemical facts obtained by the processes he used.

The jaborandi leaves, he tells us, have an odour difficult to define, but which recalls to a certain degree that of dry leaves or hay. This odour, which is faint when the leaves are intact, becomes more manifest when they are bruised. The taste also is weak; it is, however, slightly bitter when the leaves are masticated.

Fourteen grammes of leaves, reduced to a coarse powder, were submitted to distillation with 200 grammes of pure water, the heat being continued until one-third of the water had passed over. The liquor so obtained exhaled strongly the odour of the leaves, and had a very slight peppery taste; it was colourless and presented a scarcely perceptible turbidity, but no globules could be seen floating on the top. Treated with phosphomolybdic acid, with the double iodide of mercury and potassium, or with solution of iodine in iodide of potassium, it did not give any precipitate or turbidity. Consequently the odour of the leaves would appear to be due to a volatile principle; and further, the liquid obtained by distillation does not contain any volatile alkaloid.

The water which had not passed over was separated from the leaves and filtered. It was of a red brown colour, and presented also the odour of the leaves; but it had a bitter taste. It gave no precipitate with either the iodide of mercury and potassium

or with solution of iodine in iodide of potassium, showing the absence of any alkaloid. Phosphomolybdic acid, it is true, produced a dirty green turbidity; but vegetable infusions generally are clouded by this reagent, although they may not contain any alkaloid. Further, the application of Stas's test to the liquid that remained with the leaves in the retort, failed to reveal the presence of any organic base.

Finally, the aqueous liquid which did not distil over was evaporated to dryness. The residue was brown, bitter, and very soluble in water. It was treated with boiling alcohol, which only dissolved a part, and filtered. The alcoholic liquid was bitter, whilst that which remained on the filter was brown, but had no bitterness.

From these experiments, M. Rabuteau concluded that the jaborandi leaves have an odour due to a volatile principle which is not analogous to the essential oils contained in aromatic plants. It has a bitter taste, due to a principle soluble in water and in alcohol, which can be separated easily by heating the aqueous extract of the leaves with alcohol. Lastly, the leaves do not appear to contain any alkaloid.

M. Rabuteau had intended to await a further supply, to study the effects of the bitter substance which he looked upon as the active principle. Meanwhile, having seen M. Gubler's report, and although he had but eleven leaves, weighing 2.90 grammes, at his disposal, whilst from the above results, added to the fact that the leaves when masticated only slightly increased the flow of saliva, he had not much faith in the properties attributed to the drug, he resolved to experiment with them upon his own person. The 2.90 grammes were therefore reduced to powder, and about 10 o'clock in the evening, he prepared from them about an ordinary tea-cupful of infusion. This he took when nearly cold, one half alone and other half with the addition of a little sugar. The sugar, however, was scarcely necessary, since the taste of the infusion was not disagreeable. Ten or fifteen minutes after M. Rabuteau had drunk this infusion his forehead became moist, and he went to bed. Sweating came on shortly afterwards, and at the same time an abundant salivation, which continued during nearly two hours. The sweating began to diminish about an hour and a half after the commencement of the experiment, and ceased at nearly the same time as the salivation. The buccal temperature was noted during the experiment, and was found to oscillate between 83.8°F. and 98.8°F., the thermometer being placed under the tongue. There was, therefore, scarcely any abnormal heat. Nevertheless, the temperature was highest when the effects of the medicine were most active, about three-quarters of an hour after the infusion had been taken. After changing his wet shirt about midnight, the author slept well.

In this first series of experiments M. Rabuteau found that there were three points to consider with respect to these leaves; 1. A volatile principle; 2. A part soluble in water and perfectly flavourless; 3. A part insoluble in water, but soluble in alcohol, and having a bitter flavour. He was deeply interested in ascertaining which of these three parts was the active element, and for this purpose Dr. Coutinho gave him the last particle of jaborandi he had in his possession, amounting to just 2.75 grammes of the material. This small quantity was reduced to powder, and distilled with about 200 grammes of water, the operation being continued until half of

the liquid had passed into the receiver. The water collected in the receiver possessed the smell and the taste previously noted, and contained the chief part of the volatile principle disengaged from the leaves during distillation. M. Rabuteau drank this water and found no particular effects from it. Consequently, in so far as it is possible to judge from an experiment made with so minute a quantity of the substance, the distilled water of jaborandi does not possess the same sudorific and sialagogue properties as the infusion of this drug.

The decoction remaining in the receiver of the distilling apparatus was filtered and evaporated to dryness in the water-bath; the watery extract thus obtained was heated by alcohol, which separated it as before into two portions, the one soluble, and the other insoluble in this liquid. M. Rabuteau dissolved the flavourless part, insoluble in alcohol, in forty grammes of cold water, which he afterwards took and again felt no particular effects. He therefore drew the conclusion that that part of the watery extract which is insoluble in alcohol does not possess the sudorific and sialagogue properties of jaborandi. Finally, eight days afterwards, M. Rabuteau dissolved in water and took the part of the watery extract soluble in alcohol; this possessed a remarkably bitter flavour. This time he felt very decided effects, although the weight of bitter substance he took did not at all exceed 15 centigrammes. These effects consisted in a very considerable amount of salivation, to the extent of 240 grammes of saliva in the hour. It was not accompanied by any decided perspiration, only by a slight moistening of the forehead and the lumbar regions, with a slight shivering at intervals of about ten minutes. Judging from the last experiment; it is the bitter principle of the jaborandi which is the active sialagogue and sudorific principle. The same experiment seems to demonstrate that the sialagogue effects are those which are most easily produced, since these effects are the most noticeable even when the active substance has been taken in very small doses. When the dose is a little stronger, the sudorific effects are more considerable. M. Gubler, who tried this drug at the Beaujon hospital, reports that it has always acted as a powerful diaphoretic and an incomparable sialagogue. Its action becomes evident a few minutes after it has been taken, and almost with certainty. Very soon after it is administered, the sweat rolls down the face and the whole surface of the body. The saliva flows in such abundance that articulation becomes almost an impossibility; as much as a pint and a-half has been collected in less than two hours. At the same time the bronchial secretion has been observed to increase, and in one or two cases diarrhoea supervened. It is a remarkable fact, that the employment of heat, as M. Coutinho has remarked, has but a slight influence in the production of the sudorific effects of jaborandi. Whilst it is of paramount importance where our indigenous sudorifics are concerned, it is certainly not unavailing to administer jaborandi in a very hot infusion, and to cover the patient up warmly in bed; but these conditions are by no means necessary to develop the power of the new sudorific. Thus in one experiment, a person who is by no means subject to sweatings produced a copious perspiration in himself, by taking a glass of jaborandi scarcely warm, while he was going about his ordinary business. M. Gubler believes that a great future is in store for this new remedy, which he considers to be the first incontestable specimen of a diaphoretic

truly worthy of the name, that is to say, of a medication having the power of directly inducing the secretion of sweat by an elective action—by a special stimulation of the sudoriparous apparatus. The form of administration is from four to six grammes of the leaves in a cup of warm water, or if given in cold water the same results ensue. Unfortunately, no jaborandi is to be procured in Europe at the present time, so that further experiments as to the value of this remedy have to be made, and the place it will hold amongst therapeutical agents yet remains to be determined with precision and certainty.

NEEDHAM ON INSANITY IN RELATION TO SOCIETY.

Dr. Needham has reprinted a paper published in the *Transactions of the St. Andrew's Medical Graduates' Association*, on *Insanity in Relation to Society*. Dr. Needham is one of those who think that the increase of insanity is not only apparent but real; and that the arguments adduced by writers who hold the contrary opinion are outweighed by others, which show that the increase of the numbers of the insane in recent years exhibits an extraordinary development of insanity quite disproportionate to that of the population. He then proceeds to point out some of the influences which operate most strongly in the causation of the insanity. And first, with regard to civilisation; it is a question, he says, to which no satisfactory answer can be given, whether or not insanity prevails to an equal extent in civilised and in uncivilised countries, inasmuch as the information obtainable with regard to barbarous nations is small and unreliable. We may, however, concede that the development in the two classes of persons will be in opposite directions, and where there is a higher organisation and more complex mental condition, the morbid mental manifestations will assume a more active and definite form, and *vice versa*. This is undoubtedly true not only of civilised and uncivilised nations, but of rural and urban populations—amongst the one idiocy, imbecility and other evidences of imperfect development and activities will predominate; amongst the other, mania with delusion, acute melancholia and the results of mental strain and overwork. Real civilisation tends to prevent rather than promote insanity; as Sir James Cox says, 'insanity is a disease of ignorance.' Here we have the key-note of the causes which originate, and the remedies which are the cure of the evil. True education and its successors are best calculated to repair the injury, or prevent its extension. The author deplores the present state of education, and says the state of education limits the possibility of scientific instruction, and of the appreciation of the laws of public health; and yet 'it is certain that, without some knowledge of hygienic physiology, the full force and bearing of healthy or unhealthy conditions of life can never be appreciated.' Habits the most pernicious are indulged in with the freest licence, the laws of nature are outraged, and diseases supervene. 'Of these habits, that of intemperance assumes an unfortunately influential position. Of 1,029 patients admitted into the York Asylum, intemperance was the principal cause of the attack in nearly one-sixth of the number; and in a very much larger proportion of the cases it was assigned as the cause, and doubtless had a co-operative influence.' It is given as the cause in one-third of the whole of the admissions into American asylums, and the

statistics of insanity in France, Italy, Holland, Germany, and Sweden, shows its evil effects. In the great asylum at St. Petersburg, out of 997 patients admitted during ten years, 837 were said to have been reduced to a state of insanity directly or collaterally by this vice. The prejudicial influence of intemperance is not confined to the mere physical effects of alcohol upon the system, but depends largely upon the pauperism resulting from the direct expenditure of means, or loss of capacity for work, in the one generation, and the impaired or depraved mental standard in that which succeeds it. Intemperance and insanity are both strongly hereditary, and seem to be convertible in the offspring.

Insanitary conditions of life, such as overcrowding, favour the production of insanity. The Commissioners in Lunacy for Scotland observe, when commenting on the crowded and indecent state of the houses of the lower class of Scotch, 'the more these details are considered, the more hopeless will appear the task of remedying the evils which they shadow forth, until measures are adopted for raising the character of the masses, and training them to higher aspirations.' It must be remembered, says Dr. Needham, that the mere present is not that alone to which we have to look. Defects do not end with the individual, but descend from one generation to another, assuming constantly new and varied forms. And a knowledge in the individual of inherited predisposition may, and should materially influence his course of procedure and mode of life. Sound mental discipline, the habitual exercise of mental hygiene, and the employment of self-control combined with attention to physical health, may secure him against any active development of insanity. Insanity in the past or present should be made a legal obstacle to the marriage of an individual, and it would materially improve the mental and physical prospects of the race, if the marriage of blood-relations were altogether prohibited by law.

G. F. BLANDFORD, M.D.

MALINVERNI ON A CASE OF ABSENCE OF THE CORPUS CALLOSUM WITHOUT DISTURBANCE OF INTELLECT.

In the hitherto recorded cases of absence of the corpus callosum in man, there has also been mental deficiency; and the two conditions have been regarded as closely associated. Dr. Malinverni, Professor of Pathological Anatomy in the University of Turin, has published an interesting history of a case in which, although the corpus callosum, the septum lucidum, and the convolution of the corpus callosum were wanting, the intellectual faculties were entire. The following abstract is taken from the *Gazzetta delle Cliniche*, no. 15, 1874.

In a man, aged forty, who had died of gastro-enteric disease, and who, during life had shown no signs of alteration or deficiency of the intellectual faculties, it was found, on making the necropsy, that the corpus callosum was entirely wanting, together with the septum lucidum and the great cerebral convolution which surrounds the corpus callosum. On separating the hemispheres, the fornix, with its pillars, and the choroid plexus were at once seen. After hardening in alcohol, an examination of the brain gave the following results.

The cerebral mass, when viewed externally, did

not present any peculiarity; the form, number, size, and duration of the convolutions, and the depth of the sulci, were such as are met with in most normal brains. The fissure of Rolando was distinct. The fissure of Sylvius was deep, and the marginal convolution which surrounds it was well marked. The island of Reil presented four distinct processes.

The cerebral lobes in each hemisphere were symmetrical, and normally divided. The convolutions at the base were indistinct, especially those of the frontal lobe, which was bounded by the sulcus in which lay the olfactory nerve.

Viewed internally, the hemispheres presented a rare anomaly, viz., absolute want of the great convolution which runs over and surrounds the corpus callosum—the *processus cristatus* of Rolando. In the absence of this, the convolutions of the inner surface of the hemispheres presented the following appearance.

In the middle part of each hemisphere there descended four well-marked convolutions, divided to the base by deep sulci. These convolutions covered in the lateral ventricles, the optic thalami, corpora striata, and fornix. These four median convolutions were formed of the largely developed and extended (usually small and irregular) convolutions of Reil. In front of these four convolutions, three much more voluminous convolutions arose from the inner surface of the anterior cerebral lobe: these did not represent any normal convolutions, and might be regarded as compensatory for the want of the convolution of the corpus callosum. Of these, the two lower ran horizontally forwards; the third passed, somewhat obliquely, upwards. All three joined the inner margin of the frontal lobe.

The inner convolutions of the occipital lobe, five in number, were small, and ran obliquely upwards and backwards.

On looking at the brain in the middle line from the base, it was seen that the interhemispheric fissure was somewhat widened in consequence of the absence of the corpus callosum. The optic commissure was well developed. The lamina cinerea passed into the anterior commissure instead of the corpus callosum. The peduncle of the corpus callosum was present. The tuber cinereum was distinct, and the mammillary eminences well developed. The cerebral peduncles were of normal form and size.

On separating the cerebral hemispheres, the corpus callosum and septum lucidum were seen to be absent, and in their place the fornix was seen at the base; the corpus fimbriatum was distinct. The third ventricle and the structures in its neighbourhood were normal; the soft commissure was rather well marked.

In consequence of the absence of the septum lucidum, the lateral ventricles communicated freely with each other; the anterior cornua were in relation with the posterior extremity of the frontal lobes; the posterior cornua were closed in by some of the convolutions of the occipital lobe; the sphenoidal (descending) cornua and the cornua Ammonis were small. The corpora striata were rather small anteriorly. The cerebellum, pons Varolii, and medulla oblongata were normal.

With the exception of the anomaly above described, the encephalon presented no trace of organic lesion. The proportion of grey to white substance was normal. After removal of the meninges, the encephalon weighed 931 grammes; two other healthy brains, examined for comparison, and similarly

hardened in alcohol weighed, one 898 grammes and the other 990 grammes.

Professor Malinverni arrives at the following conclusion from a consideration of this case.

If a considerable portion of the brain may be absent without lesion of the intellectual, sensory, or motor powers, as was observed in the present case, we must be cautious in accepting the observations relative to the use of the corpus callosum, or to the functions of certain cerebral convolutions. We must not always accept the generally received axiom that there is the most intimate relation between matter and function in all organs, since the volume of the cerebrum is not always in proportion to the amount of intelligence.

The original memoir is illustrated with three plates. A. HENRY, M.D.

COMPARATIVE PATHOLOGY.

LEUCOCYTHÆMIA IN DOMESTIC ANIMALS. BY PROFESSOR O. BOLLINGER OF ZÜRICH.*

The number of observations on leucocythæmia in our domestic animals is still so scanty, that the relation of new cases must still be of some interest.

Some time since, I published a case of leucocythæmia in the pig (*Schweiz. Archiv für Thierheilkunde*, Band xxiv. 1871): I have since observed two cases in the dog, which I will now describe.

1. An old large house-dog had for some time shown symptoms of some disease. He lost his appetite and became thin; and one of the most important symptoms was a rather considerable swelling of the lower surface of the neck, which, on examination, was found to be referable to a distinctly evident enlargement of the lymphatic glands. The veterinary surgeon under whose care he was, diagnosed disease of the glands. As the tonic treatment employed had no effect, and the animal seemed hopeless, the owner resolved on his death. The fresh entrails were sent to me for examination, which gave the following results.

There was splenic and lymphatic leucocythæmia. The proportion of the white to the red blood-corpuscles was about 1 to 5. There were hyperplasia of the spleen and of all the lymphatic glands, and leucocythæmic infiltration of the lungs and liver. The lungs were much distended; the pulmonary pleura was normal. Their tissue was slightly emphysematous, of a pale red colour, anæmic; on close examination they were found to be studded nearly throughout with numerous punctiform and linear milary and submilary greyish white deposits, which on microscopic examination were found to consist of lymphoid cells. The bronchial glands were much enlarged—some to the size of a pigeon's egg—and formed a mass larger than a fowl's egg. On section, they were seen to be of a grey white colour, with dirty pigmented spots, moderately rich in juice, and of the consistence of marrow. From these glands and the anterior mediastinum a thickening and sclerosis of the cellular tissue of the neck extended outwards along the trachea; it had a pale grey white colour, and enveloped the nerves and large vessels to the thickness of one or two centimètres. A part of the muscular structure of the neck was also

encased in the hardened tissue, which also, near the lower end of the trachea, contained several muddy yellow caseo-purulent deposits, varying in size from a hempseed to a bean. These consisted of pus-corpuscles and their débris; in the indurated tissue, deposits of round cells could be recognised only in parts. All the cervical glands were enlarged to the size of a pigeon's egg or less, and were of greyish yellow white colour, and medullary consistence. The heart was of ordinary size; the walls were rather thick, firm, and of brown red colour. The pericardium was normal. The blood in both sides of the heart was partly fluid, partly loosely coagulated; it was of a clear red colour, and on microscopic examination showed such an increase of the white corpuscles, that there were about five to one white. This proportion was found also in the blood of the coronary veins. The liver was greatly enlarged: it weighed about 2 lbs. 10 oz. avoirdupois; its edges were rounded, its tissue was of a pale yellowish colour, the acini were very distinct, and some of them very yellow in the centre. Pale red blood escaped from the larger branches of the portal vein. On fine section of the organ after hardening, the whole tissue of the liver was found studded with an extraordinary number of lymphoid cells. Not only was Glisson's capsule, in its fine ramifications among the acini, changed into rows of cells from 0.5 to 0.8 millimètre in width, but there was an abundant diffuse deposit of lymphoid cells between the rows of gland-cells in the acini themselves. The liver-cells appeared quite intact, and mostly contained only two or three nuclei. Here and there, the fine bile-ducts were found to be plugged and obliterated, having a dull grey opaque appearance, and filled with biliary concretions. The spleen was enlarged about tenfold. It weighed about 2½ lbs.; and was 21½ inches long, 6 inches broad, and 2 inches thick.* The capsule was shining, very greatly distended, and of a pale flesh-red colour. On the surface was observed five or six prominent softish nodules as large as a walnut: their colour in the centre was diffuse whitish grey, on the periphery reddish grey. On section, the nodules were proved to be very pure in blood; both on superficial examination and under the microscope they perfectly resembled Malpighian corpuscles. The remainder of the tissue of the spleen was found on section to be of a pale flesh-colour, anæmic, and rather firm. On microscopic examination, besides an increase and thickening of the normal structures there was found a considerable diffuse deposit of lymph-cells. The mucous membrane of the digestive tube, and the lymphoid glands of the intestines, were normal. The mesenteric, epigastric and portal glands were remarkably enlarged; some of them were as large as pigeon's eggs, of a dull grey white colour on section, and of medullary consistence. No examination of the kidneys or of the marrow of the bones could be made.

In considering the changes described, we have before us an instructive example of the lino-lymphatic form of leucocythæmia. Besides the striking increase of the white blood-corpuscles, the remarkable enlargement of the spleen and of all the lymphatic glands calls for attention, as well as the leucocythæmic infiltration of the liver and lungs, hitherto described only in the pig. Whether and how far the sclerotic thickening of the cervical

* Virchow's *Archiv*, Band lix. Hefte 3 and 4.

* The normal spleen of a dog of similar size weighs about 9 ounces, and is 9 inches long, 2 inches broad, and 0.6 inch thick.

cellular tissue, extending on both sides of the trachea from the mediastinum toward the larynx, and containing caseo-purulent deposits, was connected with the general leucocythæmic disease, I will not attempt to decide. The cellular nature of the deposits, as well as their locality, which at first sight suggests a connection with the thymus gland, favours the idea that such relation existed. On the other hand, especially when we take into consideration the caseo-purulent deposits, there appears to be some ground for assuming a traumatic origin for this change.

As leucocythæmia is known to present many analogies with other diseases arising from absorption and contagion, I was desirous of not losing the opportunity which offered itself of testing the question, and made the following experiment.

The juice from a fresh leucocythæmic splenic nodule was mixed with a 0.5 per cent. solution of culinary salt, and a syringe (Pravaz's) was injected through the right thoracic wall directly into the lung of a small healthy dog.* The animal did not show any signs of disease after the operation, and was killed by strychnia four months afterwards. On section, all the organs were found normal, especially the spleen and lymphatic glands; the number of white corpuscles in the blood was not increased. In the right lung, corresponding to the point where the inoculation was made, there was a subpleural firm nodule as large as a lentil, with a yellowish-white centre and red nodule; microscopically, it consisted of firm fibrous connective tissues with central calcification.

Mosler has also performed experiments with inoculation on dogs, by injecting human leucocythæmic blood into the healthy animal, but also with negative result (*Die Pathologie und Therapie der Leukämie*, Berlin, 1862).† At the time of making his researches, Mosler was not aware of the occurrence of leucocythæmia in the dog; and he explains the failure of his transfusions by the non-occurrence of the process in this animal.

It is evident that the above described negative results of inoculation from dog to dog, as well as of Mosler's inoculation, from man to dog, do not disprove the metastatic nature of leucocythæmia, and that further observations are required. Virchow (*Die Krankhaften Geschwülste*, Band ii.) explains the course of leucocythæmic disease by assuming that the blood undergoes certain chemical and morphological changes in consequence of hyperplasia of a lymphatic organ, and that then, as a kind of metastasis, heteroplasmic disease of other organs takes place. Leucocythæmic metastasis is thus perhaps to be

* This method was chosen in consequence of my having obtained with it positive results from the inoculation of human tubercle into dogs, which are known to be inoculated with difficulty with tuberculous products.

† In a case of extirpation of the spleen in a dog which survived the operation, and was killed ten minutes afterwards, Mosler (*op. cit.*) found in the great omentum, which was hyperæmic, numerous dark red nodules varying in size from a lentil to a bean, and having externally, and even on section, a great resemblance to spleen and tissue. These spleniform tumours were found, on examination by Roth, to be lymphomata, with dilated vessels and hæmorrhagic; and Mosler concludes that there was a direct relation between the want of the spleen and these new growths. This conclusion is not supported by my observations, inasmuch as multiple spleniform teleangiectases of the omentum are often met with in dogs, whose spleen at the same time is perfectly normal.

explained by the transportation of a contagious material and by a kind of inoculation.

(To be continued.)

ANATOMY AND PHYSIOLOGY.

VON MIHALKOVICS ON THE ANATOMY AND HISTOLOGY OF THE TESTICLE.—V. von Mihalkovics (*Bericht der Math.-phys. Classe der Königlichen Sachs. Gesellschaft der Wissenschaften*, 1873), under the direction of Ludwig and Schwalbe, has investigated the course, structure, and contents of the seminal tubes, the interstitial tissue of the testicle, and the lymph-vessels and the blood-vessels of the testicle and epididymis. Besides those of the human subject, the testicles of the rabbit, guinea-pig, rat, mouse, dog, cat, hedge-hog, boar, goat, bull, and several birds (pigeons, &c.), were examined. The paper is beautifully illustrated with several coloured plates. The author has arrived at the following conclusions.

1. The convoluted tubules form a network by dividing dichotomously. The terminal branches arising from this division are connected together by loops. No bud-like dilatations of the wall of the seminal tubes are to be found in the cortical layer of the human testicle. The author thus disposes of the view that the convoluted seminal tubes arise by blind extremities, as supposed by Beale, Henle, Kölliker, and Sappey.

2. The tubuli recti are not simple prolongations of the contorted tubules, but excretory tubes, which lie in the tissue of the organ of Highmore and in the lower end of the septa. They are considerably narrower than the contorted tubules, and are lined with a low cylindrical epithelium.

3. Supporting cells (*Stützzellen*) and germinal nets (*Keimnetz*) are artificial products. They owe their origin to the coagulation of a tough substance, rich in albumen, which lies between the seminal cells. On the addition of hardening reagents, coagulation occurs, and a network appears between the seminal cells.

4. The interstitial cells are constituents of the testicle, whose analogues are also to be found in other organs (coccygeal and carotid glands, and corpus luteum).

5. The connective tissue of the testicle consists of finer and stronger bundles of connective tissue, which form networks and are enveloped by endothelial cells. The mesh-spaces are in many places bridged over by their endothelial membrane, which then passes over to and becomes continuous with the outermost layer of the seminal tubes, and also envelops the blood-vessels. These endothelial membranes consist of a wide-meshed trellis-work of exceedingly fine fibres of connective tissue, over which endothelial cells are stretched. Each such endothelial lamella possesses many fine openings.

6. The lymph-passages arise partly in the mesh-spaces of the connective tissue enveloped in endothelium, and partly in the spaces of the individual lamellæ of the walls of the seminal tubules. Proper lymph-vessels enclosed within tube-like walls do not occur in the parenchyma of the testicle. In testicles where the interstitial substance consists principally of cells, the primary lymphatics form free passages between their cells. From here the lymph flows into

larger excretory passages, which are already lined with endothelium.

7. A capillary network of blood-vessels, lying in intimate connection with the membrana propria, is closely woven round the seminal tubules.

8. The epididymis is not only an excretory tube, but also the place for the secretion of the fluid constituents of the seminal fluid. The blood-vessels form a dense capillary network in the non-muscular wall of the canal of the epididymis. This network lies immediately under the cylindrical epithelium, and presents a striking resemblance to the divisions of the blood-vessels in the ovarian follicle.

WM. STIRLING, D.Sc., M.B. (Leipzig).

LE BLANC ON ASPHYXIA THROUGH INSUFFICIENCY OF OXYGEN.—In a letter to M. Dumas, M. Le Blanc says: M. Paul Bert has made known the results of physiological experiments of great interest relating to a sojourn of the learned professor in a situation where the air could be artificially rarefied to several degrees. These experiments prove that the physiological effects of a rarefied atmosphere are due to the diminution of exterior pressure which reduces the tension of the oxygen in the gas inspired. M. Bert has wished me to state my own experiences in mines where the proportion of the oxygen of the air was notably lowered. I have lost consciousness in an ascending 'bord' in a gallery of a mine at Huelgoat (Finisterre). Afterwards I received some of the air to analyse. The air was free from carbonic acid; it had remained stagnant in a 'bord' where the vitriolisation of the rock, charged with pyrites, was very rapid. The analysis indicated: oxygen, 9.6; nitrogen, 90.4; carbonic acid, 0.0. Now, the tension of the oxygen in this air was exactly that of the oxygen of normal air at a vertical height corresponding to a barometric pressure of 0.34 metre of mercury. At this degree of rarefaction, M. Bert has proved, by artificial means, the necessity to inspire air of which the oxygen is more condensed, in order to escape asphyxia.

SURGERY.

PARONA ON A CASE OF VARIX OF THE VENA DORSALIS PENIS TREATED BY INJECTION OF CHLORAL.—Dr. Parona describes in the *Giornale Italiano delle Malattie Veneree e della Pelle* the case of a man, aged thirty, who had practised masturbation to a moderate extent from the age of eighteen, and could not obtain an erection the first time he attempted coitus. After this failure, he resumed his vicious habit; but at the end of three years he one night made a fresh attempt at connection, and contracted a gonorrhoea which lasted four or five months.

Dr. Parona, on being consulted, found that erection was incomplete, in consequence of a want of turgescence of the glans, and that the dorsal vein was varicose. Rightly attributing the defective function to disordered circulation, he injected chloral into the vein. Two days later, erection was complete but rather painful; bromide of potassium was given

internally. Erection continued to be troublesome for some time; and then all inconvenience ceased.

A. HENRY, M.D.

PARONA ON ANGIOMA OF THE GLANS.—Dr. Parona describes (*Giornale Italiano delle Malattie Veneree e della Pelle*) the case of a boy, eight years old, in whom, when he was a few days old, the large development of the glans attracted the attention of his parents. Some months after birth, he passed some bloody filaments with the urine. At the age of three years, the glans had become very large towards the frænum, and discharged blood. Dr. Larghi proposed decapitation of the penis, declaring the disease to be angiectasis. Dr. Bottini believed that there was a small encysted calculus; but nothing of the kind was found on operation.

At a later period, Dr. Parona, agreeing in the diagnosis of angiectasis, cut away the part of the glans where the tumour existed. The expectation of a radical cure, however, proved fallacious, since at the inner side of the part operated on, and on the cicatrix, red elevations as large as pins' heads budded forth. The application of caustics was unsuccessful, and the new growth continued. Dr. Parona therefore determined to amputate the entire glans. Before the operation, the penis increased in circumference towards the extremity, which was as large as an adult thumb; the prepuce was red, and large serpentine veins ran between the mucous and cutaneous layers. At the orifice of the urethra, and towards the seat of the frænum, were irregular enlargements of fleshy consistence, and resembling a mass of varicose veins. The urethral mucous membrane, as far as it could be seen, was red and granular. On the glans were sky-blue spots dotted with red; it was of natural consistence, and did not manifest fremitus or pulsation; and became intensely red when the boy stood long on his feet. The corpora cavernosa, at the end next the glans, were small.

On the eighth day, the wound was healed, and the child passed urine. After a time, the urethral orifice contracted so much, that it was necessary to have recourse to gradual dilatation.

The glans having been divided longitudinally, the extremity of the corpora cavernosa was seen to be well developed in proportion to the age of the boy, and unaltered. In the parenchyma of the glans, both at the circumference and in the centre, there were many more or less circumscribed points where the tissue was of less density, and redder, and which, when emptied of blood, appeared spongy. The urethral mucous membrane was covered in great part with reddish granulations of greater or less size. Microscopic examination showed well marked characters of angioma to be present.

A. HENRY, M.D.

MENZEL ON PARTIAL FRACTURE OF THE TIBIA IN AN ADULT.—A case of partial or 'green stick' fracture of the tibia, occurring in a man forty-eight years old, is recorded by Dr. Menzel, of Trieste, in the *Gazetta Medica Italiana-Lombardia* for March 28. This injury is by far most common in children. Dr. Menzel says that, in sixty cases observed during life, the bones of the forearm were in nearly all the seat of injury.

Of partial fracture in the adult, Gurlt has collected seven cases; in six of which the femur was affected, and in one the radius and ulna. Dr. Menzel describes his case as follows.

Antonio Gullich, aged forty-eight, was knocked down by a cart loaded with stone, on December 4, 1873. One of the wheels passed over his left leg. He was carried to the hospital; and on the inner side of the leg there was found a transverse lacerated wound, with greatly crushed edges. There was no dislocation, abnormal mobility, or crepitus; the diagnosis was contusion without fracture. On the following days, the part became swollen; and on December 9, there was distinct dulness in the lower lobe of the left lung, with rusty sputa. On introducing the finger into the wound, the inner angle of the tibia was found to be denuded, but no fracture could be detected. There was, however, some elastic mobility of the bone at the seat of fracture. His general condition became worse; the presence of pneumonia removed all hope of saving him by amputation, and he died on December 23, nineteen days after the injury.

At the necropsy, the ordinary appearances of pyæmia were found. The left tibia was partially fractured between the inferior and middle thirds, at a part corresponding to the cutaneous wound. About seven-eighths of the periphery of the tibia were divided transversely; the remaining eighth, corresponding to the inner angle, was perfectly intact, presenting not a trace of fissure. The inner angle corresponded precisely with the external wound. There could be no doubt that, when the injury was inflicted, the wheel came into contact with the inner angle of the tibia, and that the bone was broken on the opposite side in the same way as a stick bent over the knee breaks on the convex and not on the concave side. The fibula was not injured.

A. HENRY, M.D.

CASELLI ON AMPUTATION OF THE TONGUE IN A CHILD.—Professor Azzio Caselli relates (*Bullettino delle Scien. Med.* part v. vol. xvi., quoted in *Gazzetta delle Cliniche*, no. 14, 1874) the case of a boy, aged nine, who injured his tongue by falling with a stalk of hemp in his mouth. A cancerous tumour followed, and in the course of about two years extended over the whole right half of the tongue, except the apex; it affected the middle part of the left half, and the right side of the floor of the mouth. At the part where the tumour had commenced there was a large ulcer, which discharged blood and ichor. There was no enlargement of the neighbouring lymphatic glands; but the boy was emaciated and anæmic.

He was admitted into hospital on September 1, 1873. He was found to have a very acute attack of glossitis, which had followed the mastication of irritant substances, and which interfered with breathing. This was subdued in a few days by local blood-letting, cold applications, and the administration of food through a tube introduced by the nostrils. On the 11th of the month, Professor Caselli proceeded to remove the entire tongue by Rizzoli's method, dividing the lower jaw near the median line, and applying a ligature. On the fifth day, seeing that the tumour was slow in coming away, he removed it by a Chassaignac's écraseur; there was no hæmorrhage. In thirty days the wound was quite healed, and deglutition and speech were normal. Although more than three-fourths of the tongue were removed, the boy can pronounce distinctly words containing the letters *s* and *z* (*ts*).

A. HENRY, M.D.

GLEAVES ON WOUND OF THE RIGHT ILIUM.—Dr. S. C. Gleaves (*Trans. of the Medical Society of*

Virginia, 1873, and *Philadelphia Medical Times*, April 18, 1874) reports the case of a stout, athletic man, aged thirty-five, who was shot with a Colt's navy pistol, the ball taking effect near the middle portion of the ilium, two inches below the crest, passing downwards and inwards nearly in a line with the symphysis pubis, and fracturing the bone through the crest. Contrary to orders, on the following day he rode ten miles on horseback. In a week he had slight fever and great pain; the wound suppurated a little. In three weeks he had high fever with violent pain, the wound having ceased to suppurate for several days. The probe passed easily for three inches, but then met with resistance; water-dressings, morphia, and mercurial purgatives were ordered. In two or three days he improved somewhat, but about three weeks later grew much worse again, became weak and emaciated, with heavy night-sweats, chills, anorexia, and symptoms of pyæmia and speedy dissolution. Careful palpation gave evidence of fluid in the pelvic cavity. There was no discolouration or tenderness in either the perineal or the inguinal region. It was then resolved to trephine the pelvis. Brandy being administered, the patient was placed on his left side, his legs slightly flexed, and chloroform was administered. An incision three and a half inches long was then made through the glutei, directly above the great sciatic notch, and the parts were carefully dissected to the bone. A trephine was applied, and its withdrawal was followed by a full flow of sanious pus, thick and offensive. A digital examination did not reveal the presence of the ball. After a pint and a half of pus was discharged, a compress was applied, and brandy and morphia given. From this time for three months a pint of pus was discharged daily, the patient taking three times in the twenty-four hours fifteen drops of tincture of the chloride of iron and three grains of sulphate of quinia, and using in the same time a pint of brandy or rye whisky. He was confined to his bed for five months, losing thirteen gallons of pus, and drinking sixteen gallons of whisky and brandy. He finally recovered.

BROCHIN ON TREPHINING THE MASTOID PROCESS.—In a treatise on the above subject, M. Brochin (*L'Union Médicale*, April, 1874), who has witnessed several operations followed by remarkable success, gives a history of the operation:—

In France it was first practised by J. L. Petit for caries of the petrous portion of the temporal bone. The proceeding has been absolutely condemned by many specialists, such as Itard and Bonnafont; but in the opinion of the author, while it is properly abandoned in cases of chronic deafness, it is indicated—1, in caries of the petrous portion of the bone; 2, in abscess of the mastoid process; 3, in cases where suppuration in the middle ear spreads to the mastoid cells, either by the progress of the malady or through suppression of the discharge from the ear.

This opinion is not theoretical, but is based upon the observation of fourteen cases in hospital and private practice reported by M. Brochin, of which only one was fatal, and that from an intercurrent disease.

[The reporter has had two cases of suppuration in the mastoid cells, one following a blow, and the other in a child of strumous habit, in which incisions followed by the use of the gouge gave exit to pus, and rapid recovery ensued.]

WM. ALLINGHAM.

MATERIA MEDICA AND THERAPEUTICS.

RAVICINI ON THE HYPODERMIC INJECTION OF QUININE IN TYPHOID FEVER.—Dr. Ravicini, writing in the *Rivista Clinica di Bologna*, January, 1874, recommends the hypodermic injection of quinine in the treatment of typhoid fever. He makes a solution of 5 grammes of sulphate of quinine in 50 grammes of distilled water, and adds 10 centigrammes of hydrochlorate of morphia. With this solution he makes, early in the morning, by means of a Pravaz's syringe, two injections, each of 85 centigrammes; two others at noon; and two in the evening. He keeps the patient under the influence of the medicine for several days, accompanying the disease in all its phases.

Under this treatment, he says, the sordes disappears from the mouth and teeth, the headache, meteorism, and gurgling in the right iliac fossa are greatly diminished, the spleen is reduced in size, and the countenance becomes more composed. He does not believe that the quinine at once cuts short the course of the disease, but that it favours its disappearance, since he has seen nearly all his patients convalescent at the end of the second week, or at most of the third. It is only when the disease has not been treated from the beginning, that it has been prolonged beyond the third week.

The morphia he believes to moderate the symptoms of nervous disorder which are so constant in typhoid fever.

A. HENRY, M.D.

EDES ON PEPSIN.—Dr. R. T. Edes has examined many of the preparations of pepsin now offered for sale, and gives (*Boston Med. and Surg. Journal*, Jan. 1, 1874) the following as his conclusions.

'Much of the dissatisfaction with pepsin expressed by physicians is due to the use of preparations which contain little or none of it.

'The pepsin made by Scheffer's process is by far superior to any other in ordinary use. The wine is feeble, but necessarily inert. Elixirs of pepsin and bismuth are humbugs. Pepsin should be administered with an acid, and with as few drugs as possible. A small amount of alcohol is not inadmissible, but a large amount retards digestion.

'Its beneficial action is not limited by the amount of albumen which it dissolves in a test-tube without change or renewal of any of the contents.'

ELECTRO-THERAPEUTICS.

BEARD AND ROCKWELL ON THE COMPARATIVE ADVANTAGES OF ELECTROLYSIS AND GALVANOCAUTERY.—Drs. Beard and Rockwell, in their *Clinical Researches on electro-surgery*, thus sum up their views on the comparative advantages of electrolysis and galvanic cautery.

1. The relief of pain of malignant tumours is best accomplished by electrolysis or by external galvanisation. Cauterisation with the galvano-cautery burners modifies the pain to a certain extent, and in some grave cases may have a more permanent relieving influence than electrolysis or external electrification; but for the great majority of cases of ulcers or tumours, where relief of pain is the leading indi-

cation, electrolysis or external galvanisation, or both combined, will best accomplish the purpose.

2. Scirrhus of the breast, where there is no ulceration, and external fibroids and goitres are best treated by external electrification and electrolysis.

3. For the treatment of polypi—some other tumours, with a base of moderate size and accessible, as of the ear, nose, larynx, and uterus—the galvano-cautery is preferable to electrolysis.

4. In cases where large blood-vessels are involved, and there is consequently great liability to hæmorrhage, the galvano-cautery is preferable to electrolysis. Moderate hæmorrhage can be easily controlled by electrolysis, especially by the positive pole.

5. Erectile tumours, superficial and subcutaneous, epithelial and encephaloid cancers in all accessible localities, may be treated with more or less success by either electrolysis or galvano-cautery, or by both combined. Drs. Beard and Rockwell are inclined to the belief that the results of a combination of the two methods would be more permanent in many cases than when only one is employed. To establish this opinion by clinical experience will require time and careful observation.

OPHTHALMOLOGY AND OTOLOGY.

QUAGLINO ON BROMIDE OF POTASSIUM IN ALCOHOLIC AMBLYOPIA.—Dr. Quaglino (*Annali di Ottalmologia*, vol. iii., and *Gazzetta Medica Italiana-Lombardia*, March 21, 1874) regards the form of amblyopia in question as a result of the abuse of alcoholic liquors; he doubts whether there is an amblyopia arising from the abuse of tobacco, or considers it at least extremely rare. Men are generally the subjects of the affection. It usually commences slowly, and is first indicated by shortening of the range of vision, or diminished clearness of distant objects, due to the obscuring of the visual field by a thin cloud. It is most marked in bright daylight and in the summer, and diminishes on cloudy days in the evening, and when the patient is in a moderately lighted place. This erethism of the retina is characteristic of the early stages of the malady. As it advances, the faces of persons appear to the patient if they were covered with a white powder, and the acuteness of vision progressively diminishes until the patient can only distinguish the medium letters of the test-scale with difficulty at the distance of a few inches. In some rare cases, there is an alteration in the power of perceiving colours or their gradations. In such cases, the centre of the field of vision is covered by a central yellowish or blue opacity. Having arrived at a certain stage, the amblyopia remains stationary for several months, both eyes being affected. The cause remaining, sight is more and more impaired, until at last large objects only can be perceived. If the cause be removed, the malady may disappear spontaneously.

On external examination, there is only increased brightness of the cornea, with some slowness of the movements of the iris. In old persons there is also varicosity of the conjunctival veins, at the corners of the eye and along the course of the recti muscles.

Ophthalmic examination in the early stages of the malady shows slight redness of the papilla, turgor of the central veins, and diminished calibre of the arteries. In more advanced cases the external half

of the papilla is colourless, tending to white; and, in some cases, the papilla has a white appearance over its whole surface, and the arteries are pale, anæmic, and small. The venous network of the choroid may be engorged and redder than usual. The blue whitening of the pupil shows itself rather readily when the case is complicated with meningitis or cerebral congestion. Rheumatism, gout, diseases of the liver, spleen, stomach, and kidneys, and atheroma of the vessels, are somewhat frequent complications.

These amblyotic patients almost always have loss of appetite, spasmodic cough, vomiting, trembling of the hands, uncertain gait, irritability of temper, and cramps in the lower limbs. Their breath has an acid or alcoholic smell; they have an earthy colour, and in old persons there is often acne. In some cases there are weakness of the lower limbs, loss of memory, vertigo, &c., indicating grave changes in the spinal cord or in the brain.

Taking into consideration the sedative action of bromide of potassium on the nervous centres of reflex action, and its effect in reducing the action of the heart and lowering the temperature, and bearing in mind the construction of the retinal vessels observed by Lewizki to follow its use, Dr. Quaglino determined to try the effect of this drug in gradually increased doses. He began by giving a gramme per diem in 170 or 200 grammes of water, and increased the dose gradually till toxic effects began to appear. He relates seven cases thus treated; in some the cure was complete, in others the disorder was arrested, and in none was there a relapse. He concludes that, if bromide of potassium causes narrowing of the arteries and veins of the cerebral membranes, it ought to be useful in amblyopia maintained by descending neuritis and by retinitis arising from insolation, by rheumatic meningitis, and by lead-poisoning. In weak and anæmic subjects, bromide of iron appears preferable; and quinine may be given with it when there is an indication of the origin of the disorder from malaria and paralysis of the ganglionic nerves.

A. HENRY, M.D.

FUMAGALLI ON RUPTURE OF THE CRYSTALLINE LENS, AND ON THE MECHANISM OF ACCOMMODATION.—Dr. Fumagalli (*Annali Universali di Medicina*, November, 1873), relates the case of a lad aged fifteen, who, while in a wood, was struck in the left eye by a branch of a tree. He felt much pain at the time, and had temporary obscurity of vision, but it was not till some days later that he found that the sight in the eye was gradually becoming more impaired. On examination, the iris and cornea were found to be sound; but the anterior part of the capsule of the lens was divided vertically in the middle, and the lens was opaque. The case was clearly one of traumatic cataract.

An important phenomenon was observed. The edges of the fissure receded from or approached each other, according as the patient looked at near or at distant objects. This, Dr. Fumagalli observes, confirms Helmholtz's theory of the mechanism of accommodation.

A. HENRY, M.D.

CARNUS ON THE ACTION OF THE CONTINUOUS CURRENT UPON OPACITIES OF THE VITREOUS HUMOUR.—M. Carnus (*La France Médicale*, April 25, 1874) reports several cases in which the value of this plan of treatment is shown, and which corroborate the experience of Dr. Onimus during the last year or so, that the continuous current mate-

rially assists in the removal of opacities from the vitreous humour, as well as synechiæ resulting from iritis, by arousing and establishing a more active condition of the intra-ocular circulation. This result is best obtained when one pole is applied to the superior cervical ganglion, and the other to the upper eyelid. The strength of the current employed appears to be that of eight or ten cells, and was generally applied twice a week.

CASE I.—Exudation into the Vitreous Humour from old specific Retinitis.—Madame F., aged twenty-nine, had suffered from hemicrania on the left side for about a year, with diplopia and a convergent strabismus on the same side. When she came under observation, she had for some time been undergoing a course of anti-syphilitic treatment, but with little benefit. The field of vision was not diminished in either eye. After one or two applications of the current the pains disappeared, and at the end of a month the power over the external rectus muscle had returned. After a time the media regained their transparency, and the normal acuteness of vision was completely restored.

CASE II.—Synechiæ from Syphilitic Iritis, and Opacity of Vitreous Humour.—Madame L., aged twenty-eight, had complained of failing vision in the left eye for some months. She could just count fingers at ten feet, and could read No. 10 with difficulty. She had pain on both sides of the head at times. There were numerous adhesions of the iris to the capsule of the lens, and the vitreous humour was hazy from exudation. After eight sittings the pains disappeared, and the opacities in the vitreous humour had much diminished. At the end of eighteen sittings the adhesions had almost disappeared, and the vision was nearly normal.

CASE III.—Madame Ch., aged thirty-two, in 1872 had acute iritis, which left the pupil permanently distorted by extensive adhesions, but did not impair the transparency of the vitreous humour. Under the influence of the continuous current twice a week for some months the pupil regained its proper shape, and the iris became free from adhesions and perfectly mobile.

CASE IV.—Sarah—, aged twenty-three, an American, a painter by profession, was seized with violent facial neuralgia, which, however, left no impairment of vision. Five years afterwards, on her arrival in France, her left eye failed her while painting; her vision became clouded, the mist lasting several days; exposure to cold appeared to be the only exciting cause. She had occasional circumorbital pain; the vitreous humour was opaque, with numerous floating bodies, so that the optic disc could hardly be distinguished. The application of electricity was commenced on May 17, 1873, with eight elements—subsequently increased to ten—applied for two minutes. The treatment was persisted in up to July, when the vitreous humour had become so far clear that the disc was visible, and the vision had much improved. Unfortunately the treatment was here interrupted by her return to America.

CASE V.—Madame B., aged thirty-four, presented herself February 18, 1873, with keratitis and subacute irido-choroiditis; the keratitis existed in both eyes, with irregular pupils from synechiæ, and with patches of opaque tissue upon the anterior capsule of the lens. With the ophthalmoscope the fundus could be seen with difficulty through the vitreous humour, which was turbid with pigmented opacities.

With the right eye she could read No. 12 at nine inches; with the left eye, No. 8 at nine inches. The treatment employed consisted in the local application of calomel, and the continuous current. At the end of a week some of the synechiæ had disappeared, and her vision steadily improved, so that on April 14 with the right eye she could read No. 8, and with the left eye No. 1, at nine inches.

BOWATER J. VERNON.

ROOSA ON NON-SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR.—Dr. Roosa, of New York (*Treatise on Diseases of the Ear*, 1873), divides non-suppurative inflammation of the middle ear into two distinct classes—1. Catarrhal; 2. Proliferous. He says that the first of these forms, unlike the second, is not at all insidious in its approach: there is always either a history of attacks of subacute catarrh of the middle ear, leaving on each occasion more or less deafness, or there is a general excess of secretion throughout the mucous tract which lines the nares, pharynx, and Eustachian tubes. The attendant objective symptoms are impairment of hearing, changes in the tympanic membrane, imperfect action of, and changes in the structure of the Eustachian tube, together with nasopharyngeal inflammation. Besides impairment of hearing, the patients suffer from a feeling of fulness in the head, and occasional tinnitus. The pathological appearances found after death are—1. Collections of mucus distending the cavity of the tympanum; 2. Thickening of the mucous membrane; 3. Filling up of the cavity by lymph.

On the other hand, the symptoms of what Dr. Roosa calls the proliferous form are, he says, much less positive than in the other. There is no sore throat, no increase of secretion in the pharynx, nares, or middle ear. It is a peculiarly insidious affection, and the tinnitus which often accompanies it is apt to be extremely troublesome. This inflammation shows a higher formation than the catarrhal, and the pathological appearances found after death present a great variety. They are chiefly connective tissue formations in the tympanum, bands of adhesion in connection with the ossicles and sides of the tympanum, hypertrophy of the bony walls, exostoses, and ankyloses.

The catarrhal form is the more amenable to local treatment. After discussing the various operative proceedings that are employed where more simple means—such as injections of medicated fluids into the tympana—have failed to relieve the condition, Dr. Roosa's conclusions, prompted by his own experience and that of others, may be summed up by saying that incision of the tympanic membrane is not a dangerous procedure; that, in his estimation, its chief value consists in furnishing a means of treating the lining of the middle ear; and that division of the tensor tympani, as practised by Weber, and the division of adhesions existing between the tympanic membrane and the walls of the tympanic cavity, are deserving of trial.

OBSTETRICS AND GYNÆCOLOGY.

BUCKLEY ON HERPES GESTATIONIS.—Dr. L. Duncan Buckley describes (*Am. Journ. Obstetrics*, February, 1874) under this title a case of a rare affection of the skin peculiar to pregnancy, and also gives a summary of eight other similar cases which he has found recorded. From the clinical histories of these nine cases he sums up the peculiar features of the disease as follows.

1. There is an affection of the skin directly dependent upon the gravid state of the uterus, which may make its appearance at any period of gestation up to the seventh month, and generally continues until the organ is emptied of its contents, and has in a measure resumed its former state. This eruption is very apt, moreover, to recur at each successive conception.

2. The cutaneous manifestations are chiefly an intense irritation, consisting of burning, itching, or stinging, and sometimes pains, with the development of erythema, papules, vesicles, and bullæ up to the size of a hen's egg, the majority of the blebs, however, seldom surpassing in size a large bulla of herpes. These vesicles are commonly in groups, but do not follow any definite nerve-tracks, appearing first generally on the extremities, and afterwards involving the larger part of the body. Exhaustion may ensue from the cutaneous irritation, but the disease is non-febrile.

3. The eruptive disease does not terminate at once after delivery, but slowly retrogrades, by the development of fewer and fewer vesicles at increased intervals, until the disposition thereto ceases entirely. An outburst of greater or less severity is most likely to happen on the third day; it is rare for any manifestations of the disease to remain a month after parturition.

4. This affection is sometimes accompanied or followed by other neurotic manifestations, as erythema, urticaria, and neuralgia, which may continue in the interval of conception, while in many instances the patient experiences perfect health in the interim.

5. This eruption has occasionally been the first indication that impregnation has taken place.

6. The majority of the cases have been uninfluenced by treatment, relief occurring only on the emptying of the uterus.

7. The children are not, as a rule, affected by the eruption in the mother, although in one case it was accompanied in two instances by a still-birth. Here, however, the first eruption was followed by the delivery of a living child, whereas the second conception gave a still-born child without any material eruption.

EARLE ON ELECTRICITY IN POSTPARTUM HÆMORRHAGE.—Dr. Charles W. Earle relates (*Med. Examiner*, February 1, 1874) a case of *postpartum*

hæmorrhage in which after other measures had failed he successfully resorted to electricity. The subject of it commenced to experience labour-pains on December 9, but the uterus seemed unable to effect the expulsion of the fœtus, and after waiting about twenty hours she was readily delivered with instruments. Without moving her, Dr. Earle says he 'sat down by the bedside to watch the condition of the uterus for one hour before putting on the binder and taking my departure. There had been such inertia of the womb during the entire labour, that I was fearful of what my patient very soon experienced.

'Without any premonition whatever, the uterus ceased its contraction, and a stream of blood, apparently as large as half my arm, came pouring from the vagina.

'I immediately introduced my right hand to the fundus of the womb, and, with my left, tried to compress the descending aorta, giving orders at the same time to the attendants to administer more ergot, to lower the patient's head, apply cold water to the abdomen, and procure a piece of ice for inserting into the uterus. All this was done rapidly, and in much better order than is usual in such cases. But what a change there was in my patient! In two minutes she had changed from a most favourable condition—indeed, from a joyous and happy one—to an exsanguine, bloodless, and pulseless state; apparently, she was moribund.

'In addition to what I had already done, I gave what stimulants could be found in the house; and keeping my hands in the position noticed above, as the most effective way of stopping the largest amount of blood, sent immediately for Dr. I. N. Danforth, who lived in the immediate vicinity. He came forthwith, and relieving me from my most fatiguing position, suggested port wine and carbonate of ammonia as the stimulant. Ergot had been given freely; ice, externally and internally, had been used; compression resorted to; stimulants and nourishing broths administered; but the hæmorrhage did not cease. Nothing, up to this time, had produced a good, strong continuous contraction of the uterus. Dr. Danforth now advised electricity; and in a very few minutes a battery was at hand; and placing one pole over the sacrum, and the other over the uterus, the current was commenced.

'The effect was instantaneous and almost marvelous.

'The uterus contracted firmly; the hæmorrhage ceased immediately; and as long as the electrical current was continued, the uterine tumour remained hard, and of proper size.

'It was necessary, however, to keep up the current for some time; for as soon as we ceased using the electricity, the womb softened, and blood commenced to flow. It was about twelve hours before we ceased using the instrument altogether. At that time the adynamic condition of the entire system, and uterus especially, seemed to be overcome, and we felt safe in leaving our patient.

'The lady was saved, and made a very comfortable convalescence. Electricity certainly contributed largely to the favourable result.'

THOMAS ON NORMAL OVARIOTOMY.—Professor T. G. Thomas reported to the New York Obstetrical Society on Dec. 2, 1873 (*Am. Journ. Obstetrics*, Feb. 1874), a case of normal ovariectomy (removal of both ovaries as a cure of the intense and incessant nervous suffering attributable only to them, and not on

account of the usual cystic degeneration) performed by him eleven days ago, which was doing very well.

This operation was first performed by Dr. Beatty of Georgia, and the above is, we believe, the only other operation of this kind. Dr. Beatty's case is reported to have been cured.

EPIDEMIOLOGY.

MOORE ON TYPHOID FEVER.—In a paper read before the Birmingham Branch of the British Medical Association in December last, Mr. R. Bond Moore gives an account of two outbreaks of disease at Sedgley Park School, which he believes to show the difference between simple sewage poisoning and true enteric fever. The first outbreak, which affected the masters, pupils and servants 'indiscriminately,' is what Mr. Moore has named the sewage-poisoning outbreak. It was characterised by diarrhœa, sickness, great languor, and much prostration. On examination of the drinking-water, it was found to be contaminated by sewage, owing to the contents of a drain leaking into the well. The well-water was pumped out, the drain was reconstructed, and the disease forthwith subsided. About seventy persons were affected in this outbreak. During the two years which followed, the health of the school was satisfactory, when Mr. Moore was called to see a boy who had arrived at the school but four days before and who was complaining. This boy's illness proved to be enteric fever, and was followed by forty-one other cases. Mr. Moore says: 'The closets used by the boys were of the old-fashioned type; eight or ten compartments leading into one common cesspool, capable of holding the soil from the boys for three months; it was then—during the holidays—emptied, flushed, and cleansed, and thrown open to the air. This state of things had existed, *innocently*, for 100 years. The boy used these closets every day during the three or four days he was up and about, and I think I shall be able to convince you that his evacuations containing typhoid germs, whatever they may be, accidentally deposited in this cesspool (finding there a bed beautifully adapted for their rapid development), were the means of occasioning one of the most serious outbreaks of typhoid fever I ever saw, or probably ever shall see, for in a few weeks there were no less than forty-two boys down with "genuine typhoid fever" at the same time; but in no instance was a nurse, master, servant, or adult of either sex connected with the establishment attacked—Why? They all lived in the same house; they all drank the same water; they all ate the same food, cooked in the same way; and indeed several of the masters slept in the same dormitories with the boys. In only one respect was there a difference, in that the masters used a totally distinct set of closets, 100 yards away from those used by the boys, emptying into a separate cesspool; the servants also used a separate set of closets, equally distinct from either masters or boys, and emptying into an equally distinct cesspool. I say then, that there is no reasonable doubt that this boy, ignorantly transferred from Birmingham, innocently became the means of infecting forty-one of his schoolmates with typhoid fever; and I think I am fully entitled to ask you to accept the correctness of these my views, for you will remember that, *in the first epidemic, boys, masters and servants were alike*

exposed to sewage-poisoning, and all were indiscriminately poisoned; while in this epidemic boys only were exposed to infection, and boys only caught the disease.

[This closely resembles the outbreak of enteric fever in the Convent of the Good Shepherd near Bristol, on which much stress is laid by Dr. W. Budd, who describes it. It is curious that in each case what is reported by Dr. Budd and Mr. Moore as an outbreak of true enteric fever following the importation of a single case, was preceded by what they have described as an outbreak of diarrhoea, and that in each establishment the drains were seriously out of order. On the assumption that the incubation period of enteric fever is always from ten to fourteen days, the case of the Sedgley Park School would be very strong; but, as there is good reason to believe that the incubation period may be as short as twenty-four hours, it is possible that the boy referred to by Mr. Moore caught his illness at the school, being, as a new comer, more susceptible than the other boys, and that the succeeding cases were rather concurrent than consequent. There remains to be explained the immunity of the masters and servants. On this point, it is to be remembered that adults are much less susceptible to enteric fever than children and adolescents, and the reporter would suggest that the evidence adduced as to the nature of the first outbreak does not prove that it was a simple diarrhoea (or what Mr. Moore calls 'sewage-poisoning,' whatever may be exactly meant by that term), nor does it exclude the possibility that some of the cases were really cases of enteric due to sewage-tainted water. On the supposition that the first outbreak was more or less severe enteric fever, the immunity of the masters and servants in the second is at once explained.—*Rep.*]

TOXICOLOGY.

SCHWERIN ON POISONING BY BLISTERING COLLODION.—Dr. Ernest Schwerin communicates to the *Berliner Klinische Wochenschrift* for November 3, 1873, a case of cantharides poisoning, the subject of which was a rather hysterical female, aged twenty-three, who had menstruated twenty days before, and, except for some nervous attacks, was in good health. A dispute with her mother threw her into a violent fit of hysteria. Her mother, in great alarm, seized a bottle which she supposed to contain a preparation of ether and valerian, and gave her fifteen drops or so on sugar. It was, however, a blistering collodion which she had taken, prepared by macerating one part of blistering fly with one of ether. The first effect was to relieve her, but in about an hour there was violent pain at the epigastrium, then cramps, and constant inclination to pass urine, with pains in the hypogastrium. Dr. Schwerin saw her about six hours afterwards. The patient was then trying to pass urine every minute: there was at times

a sort of cataleptic condition, with glazed eyes, small pulse, and repeated vomiting. Opium, camphor, poultices, and almond emulsion were prescribed. Next day the urine, though free from blood, was highly albuminous. The tongue and throat showed signs of irritation. These symptoms continued slightly for two or three days. On the fourth day the urine was free from albumen, and the patient convalescent. There were never any erotic symptoms. Dr. Schwerin concludes from this that the old view of the aphrodisiac action of cantharidin is incorrect, and that Pallé (*Journal de Brux.*, li. Août, 1870), is justified in expunging it from the list of aphrodisiacs.

[The reporter has seen some cases of poisoning by cantharides; and, although all symptoms of erotomania were absent in some, males as well as females, in others this symptom was well marked. Doubtless much depends on the dose, and on the physical and psychical condition of the patient. In Dr. Schwerin's case the dose must have been very small. The true explanation of the discrepancy may perhaps lie in the fact, that cantharidin stimulates the whole genito-urinary tract, but that the urinary organs suffer most, and in some cases bear the whole brunt of the battle. There is a naïveté and straightforwardness in the narrative of some of the older cases, which has the ring of genuine metal about it. The curious reader may consult the cases by Duprest-Rony, Dr. Chauvel, Ambroise Paré, and others, quoted by Sonnenschein in his *Handbuch der Gerichtlichen Chemie*, p. 266. There is also recorded in a somewhat scarce book called *Anecdotes du 18^{me} Siècle*, printed at London in 1785, an account of a ball given by M. le Comte de Sade, at which cantharides were mixed with the viands—particularly with some chocolate bonbons. This, although valueless as direct evidence, shows at least the current views of the day on the subject; it states: 'tous ceux qui en avoient mangé, brûlant d'une ardeur impudique, se sont livrés à tous les excès auxquels porte la fureur la plus amoureuse: les femmes les plus sages n'ont pu résister à la rage utérine qui les travaillait. Plusieurs personnes sont mortes des excès auxquels elles se sont livrées dans leur priapisme effroyable, et d'autres sont encore très-incommodées' (p. 214).—*Rep.*]

REVIEWS.

Handbuch der allgemeinen und speciellen Balneotherapie. Bearbeitet von Dr. Baumann, Dr. Camerer, Dr. O. Diruf (senr.), Dr. Grossman, Dr. Mess, Dr. Niebergall, Dr. Petri, Dr. Reumont, Dr. Stoecker, Dr. W. Valentiner, Dr. Th. Valentiner. Redigirt von Hofrath Dr. Th. Valentiner. Pp. 847. Berlin, 1873.

There is a good deal of difference of opinion as to how far the best professional works are produced by the labour of one author, or by the co-operation of several. If the book is to be one of moderate size, and of a practical nature, in any degree coming under the designation of handbook, there is little question that a single author can execute it best.

There are indeed reasons for co-operation, where special subjects are handled; and balneology is one of these, for we have often been struck with the very imperfect acquaintance that some of the most intelligent bath-practitioners have with any baths but their own, not merely with mineral waters of different properties from, but with those having powers closely akin to their own ones. Indeed, the most that many of them know is limited to the place that they recommend as a *Nachkur*.

On these grounds perhaps Dr. Valentiner has made an useful experiment, in bringing together the views of those whose practice is chiefly limited to the use of particular classes of waters; and we have to thank him for having brought out the whole work at once, and not having spread it over months and years, as in the case of Virchow's *Pathologie und Therapie*, which at the end of twenty years still awaits its completion. The most obvious defect of the handbook is its want of unity. The various portions of it have not been assigned with sufficient definiteness to the different authors. Hence it results that one author does not take up a particular subject, because he thinks another one will do so. He also fails to take it up, and thus it is treated imperfectly or not at all.

Some diseases are not treated under the heads to which they are usually referred in other books; and waters used for drinking are sometimes treated under baths—for instance, iodine and bromine waters under salt-water baths. It would be easy to give more examples of this nature.

In balneological books there is always a difficulty in selecting the most appropriate arrangement of the matter. The lexicographical and geographical divisions, that according to the various classes of disease, and that based on the chemical constitution and the therapeutic action of the waters, have all had their advocates. We think that Dr. Valentiner has been right in following the last arrangement, as it ought to save an immense deal of repetition. He might have been spared a good deal of needless iteration, if he had kept a more strict hand over his contributors; and it is in this respect that one writer is able to manage the subject better than a plurality. The writers of the handbook have steered pretty fairly clear of the common fault of specialists, that of praising their own waters too highly—a fault which even the sarcastic and critical Braun has not wholly escaped. A great deal of space is occupied in the discussion of theoretical questions, and pathology is often entered into more deeply than is desirable in a work of this class. The result of this is, that the accounts of individual baths are short, and indeed often not fuller than those to be found in much smaller works. There are also indications of limited practical acquaintance with localities; and indeed, as a general rule, bath-doctors do not often visit other baths than their own. Thus, the writer on Wiesbaden is not aware of the imperfect bathing arrangements of that place; and he enumerates, among practising physicians, those who have long retired from business. In like manner we are referred, at Aix-les-Bains, to Baron Despine, father and son, while the father has been dead for some time; and at Amélie-les-Bains to Dr. Pujaud, who has been dead for several years, although his establishment retains his name. In a general work on balneology we should have expected some notice of baths, besides those of Germany, France, and Switzerland; but we find none. There are indeed some good hints about sea-bathing-places

in England, but no mineral waters—not even Bath, Burton, or Harrogate are mentioned. There is not a word about Italian waters; not even about well-known ones, such as Acqui, Lucca, or Ischia. The interesting iron springs and the baths of Bormio, on the southern slopes of the Alps, are entirely ignored.

All kinds of artificial baths, mud, pine extract, vapour, sand, &c., are treated of in the most perfunctory manner. Bath arrangements and the exportation of mineral waters are scarcely alluded to. The account of climate is good so far as it goes, but is meagre. Milk and grape cures are treated of very imperfectly.

The tone of the book is often somewhat controversial, and the writing too obviously directed against Braun, who, if this work errs on the side of over-belief, for instance, in having confidence in arsenical waters, certainly runs into the opposite extreme. But in spite of all the deficiencies pointed out, and although the book cannot be recommended to a mere student of the subject, or to a busy practitioner, who has no time to read so large a work, yet these separate essays are well worthy of the perusal of any one familiar with the subject. Dr. Reumont's account of sulphur waters, and of their use in syphilis, is one of the best. The tables of analyses, all of which are reduced to decimals, have been carefully prepared.

On the whole, we fear that this work has met with a less favourable reception in Germany than it deserved.
J. MACPHERSON, M.D.

Jahrbuch für Balneologie, Hydrologie, und Klimatologie. Von Dr. E. H. KISCH. Jahrgang 1873, Band ii. Wien, 1874.

Balneologists are greatly indebted to Dr. Kisch for the admirable record with which he presents them, of the progress of balneology and its allied subjects. In fact, it is extremely difficult to be acquainted with the latest information on these subjects, without the aid of this work. The annual summaries in *Schmidt's Jahrbücher* and in *Virchow's Jahrsbericht* are the only substitutes; and though most carefully compiled, they are more brief and less varied in their contents.

A mere enumeration of some of the principal papers in Kisch's second volume for this year, will show the variety of matter treated of. There is an article on English watering places, an abstract from the English of Macpherson and the French of Labat. Dr. Pröll's experiments on the electricity of the Gastein waters are described. There are, an account of the natural *stufa* of Monsumanno near Monte Catini, which resembles the *stufas* of the Bay of Naples and of Ischia; a new analysis of the waters of Tarasp—the chief result being the proof that the Lucius and Emerita springs are identical; a fresh analysis of the waters of Ems, showing how little the springs alter, or differ from each other; a full account, by Dr. Schuber, of the Iodine waters of Hall, in Upper Austria; an elaborate dissertation on the physiological effects of kumiss, by Dr. Schnitzler of Vienna. A high value is attached to its use; but the patient, to obtain its full effects, must live almost exclusively on it. Next, a paper by Dr. Röhrig, of Kreuznach, on the absorption of gas by the skin when dry or moist; and then follows one by Professor Benedikt, of Vienna, on the balneo-therapeutic treatment of chronic nervous affections, in which he says that he agrees with the general doc-

trines of Chapman, and finds his treatment useful in hysteria, but not as yet in epilepsy. Then follow a set of bath reports from Marienbad, Teplitz, Gastein, Tarasp, Badenweiler, Schwalbach, Nauheim, and other places. Under the division of Hydrology, we have papers on the measurement of *Grundwasser*; on the essentials of good drinking water; on the value of hydrotherapy in intermittent and spleen; and other shorter papers. Under the head of Climatology, which is not treated quite as fully as usual, there are a good résumé of the latest observations on ozone, and a paper by Dr. Schreiber on the causes of intervals of cold weather in spring. The next part is devoted to reviews of some twenty recent publications on Balneology; and includes an abstract of Pettenkofer's lectures on the relation of air to clothing, dwelling, and soil. The whole concludes with a few balneological and less formal notes, giving the latest news of many baths. The table of contents thus appears to be sufficiently interesting, and should commend the work to English readers.

J. MACPHERSON, M.D.

Observations on the Pathology and Treatment of Cholera. By JOHN MURRAY, M.D., Inspector-General Indian Army. London: Smith, Elder & Co.

The author of this practical little treatise has had forty years' experience of this disease, and the work before us 'is the result.' Dr. Murray does not pretend to throw any fresh light, either on the cause of cholera or the laws that govern its propagation, but the different stages of the disease are carefully described with the accuracy of a practised observer only too familiar with the phenomena. It may be true, as Dr. Murray asserts, that it was only after the meeting of the Constantinople congress, that diarrhoea was generally allowed to be a stage of cholera and capable of communicating it in its most intense form. But it is consistent with our knowledge that, for at least thirty years before the assembling of the Constantinople congress, diarrhoea was recognised in India, if not actually as a stage of the disease, yet certainly a premonitory symptom of the gravest significance; and on this knowledge was founded the practice not uncommonly followed by careful regimental surgeons, of having frequent inspections of their men during the prevalence of an epidemic, for the purpose of detecting this symptom (generally easily done by a glance at the faces of the affected) with a view to its immediate treatment. It is equally certain that in this country Mr. Simon strongly maintained the opinion that the evacuations of persons suffering from the so-called premonitory diarrhoea are capable, under certain conditions, of propagating cholera in its most intense form.

In common with nearly all Indian practitioners, Dr. Murray has not only nothing to say in favour of the purgative plan of treatment in cholera, but is careful to teach the danger of giving purgative medicines of any kind, more especially saline or hydragogue purgatives, during epidemics. Those who have practised their profession in the hospitals of Calcutta are familiar with the fact, that English sailors, feeling heated and feverish after a debauch and exposure to the sun, frequently have recourse to 'a dose of salts,' and after its operation, are brought to the hospital passing rice-water stools, and collapsed. Impressed with the danger of diarrhoea running on into the more advanced and intractable stages of 'congee'-like stools and collapse, the author strongly insists on the necessity of 'stopping it' at

the earliest possible period, the success which attends this plan of treatment must be kept in view in considering the elimination theory by means of purgatives.

It is needless to say that our author has no 'specifics' for cholera, and we are glad to see that he condemns the too common practice of rushing to 'strong remedies' in the desperate hope of effecting a cure by their administration in inordinate doses. This tendency was strongly evinced in this country in the epidemic of 1866, and was reprobated and ridiculed by Dr. Maclean, of Netley, in two lectures which excited a good deal of attention, and had a wholesome effect at the time. The medical journals and newspapers of the period were filled with the records of 'cures' and 'successful cases' brought about by remedies of the most opposite properties. If a patient did not die, he was supposed to have been 'cured,' forgetful of the fact that a certain proportion of cases recover under a vast variety of treatment not absolutely hurtful or poisonous, and sometimes under no treatment at all. In particular we commend what Dr. Murray says on the subject of opium. The proper time for its use is in the stage of diarrhoea; it is, like everything else, inert during collapse, but is prejudicial and often fatal in its effects when reaction begins.

On the whole, we think this little treatise is calculated to do good, to guide the inexperienced in their efforts to aid nature in the struggle for life, and above all, as we have said, to discourage the rash hands of meddlesome practitioners who try to effect their purpose by a mere *tour de force*. This we take to be the great merit of the book, and a not inconsiderable merit it is.

In the present state of knowledge 'prevention' must be the great object in view; 'cure' for cholera there is none. Many valuable lives may be saved in all epidemics by prompt treatment in the stage of diarrhoea, and not a few by judicious management and good nursing after the disease has been established, certainly not by the heroic measures which are justly condemned by our author, whose opinion is entitled to great weight as that of a wise and prudent physician, who has seen as much of this terrible scourge of the human race as any man now living.

CORRESPONDENCE.

EXCISION OF THE TARSUS.

To the Editor of the LONDON MEDICAL RECORD.

SIR,—I read with interest the account by Mr. Mac Cormac of Dr. Watson's paper on 'Excision of the anterior tarsus and base of the metatarsus.' It may be within the recollection of some of your readers that I exhibited at the Clinical Society on April 26, 1872, a man in whom I had removed the second metatarsal bone, the ends of all the other metatarsals, and the articulating surfaces of the anterior row of the tarsal bones. The case is recorded in the *Transactions of the Clinical Society*, vol. v. p. 207. This operation was looked upon at the time as unique, but I see that Dr. Watson's first case preceded it in time—though not in publication. My operation was performed by making a transverse incision across the dorsum, and turning down a flap from the upper surface of the bones, a plan which seems to me more convenient than lateral incisions, as giving an easier access to the bones, and a fuller view of their condition. The division

of the tendons has not appeared in this and similar cases to be of any moment in the ultimate result of the case.

T. HOLMES.

May 21.

MISCELLANY.

MAGITOT ON THE DETERMINATION OF THE AGE OF THE HUMAN EMBRYO.—At the meeting of the Academy of Sciences on April 27, M. Magitot (*Gazette Hebdomadaire de Paris*, May 8), read a paper on the determination of the age of the human embryo by the examination of the evolution of the dental system. The researches of the author, as well as those of the late M. Legros, have included a large number of human embryos; forming a scale or ladder, extending from the time when the individual measures two centimètres to birth. In order to fix the chronological order of the successive facts of follicular evolution, they have been obliged to accept as primary elements in the determination of the age of the embryo, documents published by various authors on the relative conditions of length and weight. After having examined the majority of these, they have been induced to adopt as the most exact the indications furnished by MM. Littré and Robin in their *Dictionary of Medicine* (Art. *Embryon et Fœtus*), and have also been guided by the comparison of a circumstance very rigorously observed by M. Gueniot in a case of abortion at a precise date.

The whole of the observations have been collected into a table which is too long for reproduction here, and which gives the state of the dentition at various periods of the age of the fœtus.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & CO., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & CO.—Calcutta: THACKER, SPINK & CO.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & CO.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & CO., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JUNE 3, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

LENTE ON THE HYPODERMIC INJECTION OF QUININE.

Dr. Frederic D. Lente has published in the *New York Medical Journal* for March, an exceedingly interesting paper upon hypodermic injection of quinine. After discussing the merits and demerits of various solutions used by himself and others, Dr. Lente says: The following formula was adopted, and has been used ever since: \mathcal{R} . Quinæ disulph. gr. i.; acidi sulphurici diluti \mathfrak{m} .c.; aquæ font. \mathfrak{z} j; acidi carbolicum liquidum \mathfrak{m} v. Solve. Place the quinine and water in a porcelain dish, over a spirit-lamp, heat to the boiling point, and add the sulphuric acid, stirring with a wooden spatula. Filter at once into a bottle, and add the carbolic acid. This gives six grains to the drachm. Even this solution will deposit some crystals at a temperature of 50° ; and, of course, at or below that temperature requires to be warmed before using. The carbolic acid also, I think, alleviates the pain of the injection, as there is but little complaint, in most cases, after the first few drops. I can recommend this with considerable confidence, so far as danger of local difficulty is concerned, since it has been used by myself and my various assistants at least one hundred and fifty times, or over three hundred insertions (each hypodermic dose consisting of at least two injections). Neither have I, nor any of the gentlemen who used it under my direction, had any serious trouble with it.* In one case, after using it twice, it produced each time a diffuse cellular inflammation of the arm, which yielded slowly to cold water applications, and I desisted, although the patient was anxious to submit to another trial, so far superior did she find this method to that by the mouth. In another exceptional case, a singular effect was produced, already noticed in this paper—anaesthesia of the part, followed by dry gangrene of a small mass of cellular tissue. This was the fourth injection of this patient, or the eighth insertion; none of the others giving any trouble whatever. Patients frequently experience a numbness of the part, sometimes lasting weeks after the operation, possibly from the effect of the carbolic acid. The injected part is usually tender for a few days after injection, when accidentally touched; sometimes inconveniently so, when the patient is at manual labour (on this account it is better to select the left arm), but it rarely incapacitates a labourer, even for half a

day. Since this solution has been used, I have met with full as many cases of trouble arising from injections of morphine, though so much smaller in bulk, as from it. All hypodermic injections, however small, will occasionally cause inflammation, abscess, and even sloughing, sometimes of a persistent character.

The question of the proper strength and composition of the solution is a vital one, as regards the ultimate success of this valuable mode of treatment; and, as it cannot be considered at all settled, I have already dilated considerably on this point, and would remark further that the inconvenience, slight though it is in a majority of cases, of introducing the needle two and occasionally three times at a sitting, and inserting sixty to ninety minims of fluid more or less irritating, is sufficient to induce the hope that a solution equally safe will be devised, which shall contain two or three times as much of the drug. It is true that by the aid of heat, applied at the time of the injection, double the quantity in the same amount of fluid may be used; and this brings up the question of concentration of the solution, which most writers have considered essential. Two ideas seem prominently to occupy the minds of those who have employed this method, both of which are probably erroneous and mischievous: one, that the solution cannot be too concentrated, provided little or no acid be used; the other, that the acid is the principal or only cause of the serious accidents sometimes attending the injections. Now, it will be found that, in cases of local trouble, more than one cause is in operation, sometimes several. Thus there may be delay in the absorption of the fluid, one portion of areolar tissue only a few inches from another absorbing more readily; this delay being also sometimes attributable to the imperfect solution of the salt, and the latter being the result usually of using too little acid.

As it respects the mode and best time for operating, the following are the author's conclusions. Having settled upon a proper solution as far as present experience enables us, there are some precautions advisable. It is important to have a gold needle, not one merely gilded. Messrs. Tieman and Co. prepare them very skilfully, and, with care, they seldom require sharpening, which may easily be done on a fine hone. The syringe and needle should be washed out after each operation, and the piston frequently oiled, as it is both stiffened and rotted by the solution. The outer and anterior portion of the arm, not too near the joints, are usually chosen for the insertions, although the outer and upper portion of the thigh present desirable localities. We have, however, injected all parts of the body, in cases where repeated injections were required. I usually make the two punctures two and a-half to three inches apart, so that the wet application, which is often desirable to prevent inflammation, may cover both. The injection should be made with deliberation. The first few drops cause more or less severe smarting, and I wait until this ceases, or nearly ceases, perhaps half a minute or a minute; then continue slowly, drop by drop, as fast as the patient can endure it, without inconvenient pain, being guided also somewhat by the rapidity with which absorption takes place, judging by the greater or less elevation of the integument around the puncture. As soon as the needle is withdrawn, I cause the patient or a bystander to put the finger over the puncture for two or three minutes, to prevent the

* Dr. Murdock has used this method to a moderate extent, and his experience is incorporated with mine. I have at different times been assisted by Dr. A. A. Smith, of New York, and by Drs. Farmington, Griffith, and Young, of the resident staff of Bellevue Hospital, who are, I understand, using this solution now in that hospital.

fluid from exuding. In case of threatened inflammation, or much soreness, I direct the patient to bind on a wet folded handkerchief or pledget of lint as a precautionary measure.

As regards the best time for the operation, the general impression seems to be that it should be done just previously to the expected paroxysm, and Dr. Moore, of Bombay, says: 'The best time is shortly before the cold fit; but it may be done during the cold stage with the effect of lessening and sometimes stopping the whole paroxysm.' I can corroborate the last observation, and shall subjoin some cases in illustration of this important point. I am not fully prepared, as yet, to say whether there may not be an advantage as regards the ultimate effect of the operation, in following the prevalent notion. But it so often happens that the severe train of symptoms attending a paroxysm of epidemic ague is mitigated, even arrested, by the injection on the spot, that, when convenient, I always give the patient the chance. But, as a general rule, I have injected without any reference to the date of the paroxysm. This point will bear further investigation. I am informed, however, by Dr. Meredith Clymer, that, in a recent report of the English army-surgeons serving in malarious regions, the verdict is decidedly in favour of administering quinine (this does not refer to the hypodermic method) during the attack.

As regards the dose, it depends, like that administered by mouth or rectum, on so many circumstances that one cannot be definite. But the variation, depending on idiosyncrasy and age especially, is not nearly so great as in the other methods. The doses of various reporters have varied from two to ten grains. The fact is that, at present, it is limited somewhat in obstinate cases by the insolubility of the drug, a dose of twelve or eighteen grains requiring of the solution here recommended two or three drachms; too large an amount of fluid except in desperate cases, where severe pain and abscesses are comparatively of little moment. My first doses were two or three grains, and the most marked results were obtained from these small doses, probably because the medicine was more largely diluted, the same quantity of fluid being always used; possibly also because the disease assumed a more obstinate type as the epidemic wore on. For the latter reason it was found necessary to increase the dose to six grains, and in a few cases to nine or ten grains. When more than six grains were employed, I usually made three injections, but sometimes used a syringe of greater capacity, and only inserted twice. When the patient has a good deal of adipose tissue, and is not particularly intolerant of the injections, forty minims may be used in one spot.

During a severe epidemic, it will usually be necessary to repeat the dose every fourteen or twenty days; in some cases every six days; and now and then every day or two. In these cases the patients are so tolerant of the injections that they care very little for them. Where the resulting soreness or inflammation is troublesome or tedious, it is better to resort, if possible, to some other treatment. During the intervals it will not usually be necessary to give any antiperiodic or tonic. In my own cases, desiring to test the value of the treatment as accurately as possible, I rarely gave any medicine, even of a cathartic nature, unless required by constipation.

BROWN-SÉQUARD ON THE LOCALISATION OF BRAIN FUNCTIONS.

Dr. Brown-Séquard, at the meeting this year of the United States Academy of Science, read a paper of great interest in relation to recent researches, which is thus epitomised in *Nature*, from advanced sheets of the report in the *New York Tribune*.

Dr. Brown-Séquard began his paper on the pretended localisation of the mental and the sensorial functions of the brain, by saying that the subject has been rendered more difficult by assumptions of physiologists upon insufficient data. Among the views which have been recently brought forward upon the localisation of nervous power in certain parts of the brain, there are two of importance: one relates to the seat of power actuating muscles, and the other is as to the seat of sensation for different nerves. In the latter particular, after noticing several exploded theories, some still pertinaciously adhered to by physicians, Dr. Brown-Séquard reviewed especially the assumption in respect to the seat of power for speech.

'Let us consider the question of the locality of the intelligence of the brain. Most physiologists are agreed that this is the grey matter of the upper parts of the brain. But the method of communication is still open to research.' (Here the lecturer drew on the blackboard a figure somewhat like a sheaf of wheat without a band around it; the stalks representing the nerves, the heads of wheat representing the cells.) 'Now you may subtract from this, by disease or otherwise, say the upper third, and still you have the nerves and the nerve-cells, and the processes can be carried on; but in the progress of such destruction downward there would eventually be reached a point where the functions of the brain could no longer exist. This view would explain the facts as we find them. But there is no case on record where the grey matter on both sides of the brain has been destroyed without the loss of intelligence, and we must regard the grey matter as the seat of the intelligence. But vast portions may be removed before the loss of intelligence becomes apparent. This I have myself tested and proved by vivisection of the lower animals.'

'Now, in respect to the locality of the power of speech. It has been said that the loss of brain power to express ideas in speech was located in a certain part of the brain. This affection is called aphonia or aphasia. There are three modes of expressing ideas—by speech, by gesture, and by writing. It is with the first only that we are concerned. Some very bold theorists have tried to locate all these powers in a particular part of the brain. Let us confine ourselves to facts. Dr. Broca of Paris has advanced the view that a certain small portion of some of the convolutions of the brain holds the power of speech. I admit that facts seem to favour this view. But we find that there is no relation between the degree of aphasia and the extent of the disease of that part, and there are cases where the destruction of those convolutions is very great, and the injury to speech very little. Secondly, we find that disease may have overtaken the anterior, the posterior, and the middle lobes of the brain, the particular convolution supposed to involve speech not being affected, and yet there is marked aphasia. Now, is some one of these lobes the locality of the power of speech? Such would be the reasoning of my opponents. We should be obliged to concede that in some persons the faculty of speech existed in one part of the brain, in

some in another, in others another, and so on *ad infinitum*. This is a *reductio ad absurdum*.

'There is the case of the paralysis of the insane, where the grey matter may be diseased on both sides of the brain. In these cases the power of speech does not seem to be involved. There are cases of aphasia where the diseased person has had the power of speech restored during delirium. The speech is coherent though the sense may not be. It is evident, then, that the faculty of speech is not actually lost in such cases; and yet we find that the third frontal convolution is actually diseased in those aphasics who talk in their delirium. But the most decisive argument is found in the cases that I have seen, where the third frontal convolution, the alleged organ of speech, has been destroyed, and yet the patients have not lost the power of speech. Therefore the theory is itself destroyed. There are fifty cases on record to show that the question of right-handedness or left-handedness does not apply in the considerations.' The lecturer here cited cases of Jacmel of Montpellier and Mr. Prescott Hewett of London. In the latter case the patient had suffered a destruction of that part of the brain for twenty years, and yet for twenty years had spoken.

'We shall now take up the question of the localisation of motion in certain parts of the brain. I am surprised at the avidity with which a certain series of facts has been accepted as proof of this theory in England. A very eminent man, of whom I should not like to say anything severe, my friend Dr. Carpenter, has accepted those views. I may say that all England has accepted them. Prof. Huxley, indeed, has written me, that he only accepted this view in part, but I cannot see how he can accept a part without accepting the whole, where even the part is incorrect. The famous experiments of Dr. Ferrier, of King's College, must here be considered. As you will see, they are not, however, conclusive. By the application of galvanism to certain parts of the brain of animals, he produced certain movements. When we do not stop to think, this would seem to prove that there are in the brain certain centres of movement governing certain parts. But it is only a semblance. A part of the facts are taken for the whole. We should know all the series before we adopt the conclusions. Let us examine the other facts.

'It is perfectly well known that the cutting away of a large portion of the brain does not produce the least alteration of voluntary movement any where. Suppose that part of the brain, say the anterior lobe, being excited by galvanism, produces a movement in the anterior limb; now suppose that part of the brain is cut away; then the anterior limb should be paralysed, for its voluntary movement is gone. Admitting that the other half of the brain should supply the place of the missing part, let us take that away also; then certainly there should be a paralysis of the anterior limbs. But there is not. This should be sufficient to invalidate the conclusions of Dr. Ferrier. But there are abundant pathological facts of this nature proving the fact beyond question. And then there are the cases of recovery from paralysis. There is no such localisation of power as Dr. Ferrier has assumed. If galvanism be applied to the severed leg of the frog, the leg will jump, although there is no brain-power in the question.

'What should have been done was to have cut the connection of parts, so that a general effect should not have been propagated throughout the brain by

the application of galvanism to a part. This would be the *experimentum crucis*. My friend Dr. Dupré of Paris has made this experiment. I made it also, before he did, but he published his before mine. But there are many other facts almost equally impressive in their character which may be cited. We find many cases where the lesion of part of the brain produces paralysis on the same side of the body, and not on the opposite side, as in the majority of cases is the rule. There is a case recorded where a ball passed directly through the brain, and it produced paralysis on the right side, instead of the corresponding side.' Here Dr. Brown-Séquard objected to having a certain class of brain-affections named after him, stating that diseases should be named from their distinctive features, and not after physicians.

Dr. Brown-Séquard then applied a similar course of reasoning to the localisation of sensation in specific parts of the brain, concluding by stating that it is evident we cannot locate the centres of either sensation or motion in specific parts of the nervous system.

OBERSTEINER ON ESTIMATION OF THE CAPABILITY OF REACTION IN THE BRAINS OF THE INSANE.

Dr. Henry Obersteiner, of Döbling (Virchow's *Archiv*, vol. ix. pts. 3-4), says that if one of the peripheral sense-organs be lightly stimulated, and the moment when this stimulus is perceived by the person experimented on be noted, it will be seen that a definite and measurable period of time intervenes, which is called the 'period of reaction.' Individual differences, by which the time of reaction is greater or less in one person than in another, have led to the establishment of a 'personal equation.' The whole 'period of reaction' may, however, be subdivided into, 1. the time necessary for transmuting the applied stimulus into nerve-force; 2. the time necessary for the stimulus to pass through the sensory nerves and the spinal cord to the brain; 3. the time which is occupied in the brain itself for converting the sensitive stimulus into a motor act of will; 4. the time required for the impulse to reach the muscles from the brain; and 5. the time required for setting free the muscular movements in the muscle itself. For the psychologist the third point is of the greatest interest, and this, following Exner (*Pflüger's Archiv*, vol. vii., p. 601) is termed the 'reduced reaction-period.' This period includes solely the events that pass in the brain, and shows how much of the time of the process beginning in the organ of sense and ending at the muscle, is taken up by the brain itself.

Dr. Obersteiner's attention has long been drawn to this 'reduced reaction-period' in the insane, with the view of getting a measure of the rapidity of the psychic events, and so a clearer picture of the greater or less facility with which the separate processes follow one another. It must be allowed that the pathological conditions of the brain allow the objection that thereby a difference in the mechanism for producing reaction enters. The instrument used is an application of an oscillating tuning-fork, simple in construction, and cheaper than most of the scientific registering instruments (made by Heinitz, of Vienna, for 2*l.*), which he calls the 'Psychodometer'—*ψυχι-δότης-μέτρον*. It consists essentially of two pieces—a platform

which has at one end a contrivance for carrying the oscillating pen, and which also has two slits to receive a smoked glass-table. The lever consists of two parts; one, the longer, being the recording pen, whilst the shorter arm is made of brass, and carries a button on the end. The swinging of the lever can be regulated by a screw. The pen is made of a piece of smooth steel, a-third of an inch wide and four inches long, so placed that the edge is uppermost, and when set swinging it does so 100 times a second. At the free end of the pen a bristle is glued on, so as, when the lever is horizontal, to just touch the smoked glass-table. There are stops placed in suitable positions to prevent the lever from oscillating too far in either direction, and the whole thing may be made fast to an ordinary table by binding-screws. The glass-table, and the stand in which it is fixed, can be worked in the slots backwards and forwards by handles. The way to use the apparatus is for the person experimented upon to place one finger on the knob and to turn his head away from the experimenter, who then draws out the platform, carrying the glass plate more or less rapidly as the circumstances require. At the very moment when by pulling the handle the pen is set free, it begins to swing and emits a distinct tone. The person experimented on marks the moment when he perceives the sound, and at once raises the index from the table by pressing the knob. The index has consequently written only so long a time as had elapsed between the generation of the sound and the marking by the finger of the operator. Since the index makes 100 oscillations in a second, each oscillation requires the one-hundredth part of a second; but since, at the first at least, the waves are large enough for estimating tenfold with ease, the one-thousandth of a second may be easily read off. If, instead of, or even together with, an impression on the auditory nerve, it be desired to estimate an impression on the hand or any other part of the surface of the body, a simple modification of the apparatus can be adopted, so that at the instant when the index begins to swing, a current of electricity is opened or closed, the notification of which by the person under experiment is made by pressing the button. Another application of the instrument consists in introducing a piece of card-paper, on which some colour is printed, in such a manner that at the moment of commencement of the lever to swing, and therefore to write, the colour is noted by the experimentee. Such coloured papers of different sorts are kept, and the plan is to say that when a certain named colour appears the knob is to be pressed as usual, but when other colours appear the knob is to be left alone. Thus the time is noted which is necessary to the conviction whether the knob must be pressed or not. A little practice for the proper adjustment of the lever is required, but the instrument is very simple, exact, and convenient, for rapidly recording a number of observations, whilst it requires no great intelligence on the part of those operated on to use it. For the solution of different questions it was first necessary to operate on sane persons, the point to determine being the knowledge of the 'reduced reaction-period,' absolute or relative, *i.e.*, the time during which the impulse starting from the apparatus, in a changed and still changing form of course, passes through the brain, and again leaves it in the form of an impulse to movement.

The first element composing the reaction-period

is that requisite for the vital force operating as impulse to impart the force necessary to be transmitted on the proper paths of the central organ. This so-called latent sense-stimulation is open to question. Exner thinks that for *the eye* it lasts about a fiftieth to a twenty-fifth of a second; for *the ear* no results are on record. Secondly, the rapidity of conduction in the peripheral nerves may be taken as 180 feet a second. Rosenthal (*Centralblatt*, 1873), has recently stated that the ordinary methods of estimating the rapidity of conduction after irritation of sensory nerves are not satisfactory, and that it is much quicker. The conduction of sensibility in the cord is placed by Exner at eight mètres a second, but this includes not only the simple longitudinal conduction, but also the action of the ganglion-cells. It is quite possible that the dark-bordered nerve-fibres of the cord conduct as quickly as the peripheral ones, and that the central cells cause the delay. Exner finds again that the rapidity of motor conduction may be taken at 11 to 12 mètres a second, the reduced rate being probably due to the cells in the anterior columns. The duration of the 'latent stimulation' in the muscles of the frog is about $\frac{1}{100}$ of a second; in the human subject it has not been measured, nor is it known whether individual differences occur. From many observations (some of which are recorded), it appears that our perception of time is enough to estimate mistakes of a few hundredths of a second.

Trials were made with persons in different bodily states, *e.g.*, when requiring rest, the instrument showing the 'reaction-period' to be 0.188 second instead of 0.134 second; or in another troubled with a pain that to some extent occupied his attention, the average being 0.175 second as compared with 0.134 second. Most striking are the contrasts between the numbers obtained when conversation was going on in the room, and during the pauses—in the former case being 0.260 second, and in the latter 0.134 second. When a little practice has been acquired, the reaction to impulse assumes such a beaten path that farther reflection is unnecessary for setting free the movement. And this appears to be a sort of reflex process, the place of which is in the brain, not in the spinal cord. The cortex of the brain as the seat of consciousness is not necessarily brought directly into play, but still exercises a great influence on the normal course of the reaction. The difference must be clearly made between the reflex actions of the cord and those arising from the higher brain-ganglia; the former are as a rule of a simpler kind, and are in no degree, or only a very slight one, dependent on the will; the latter are more complicated and more strikingly under control of the will, although they may become quite independent of it. Age has a marked influence; for although Exner found that the rapidity of nerve-conduction for young and old people is the same, yet the psychic process is somewhat prolonged in old persons. Another factor which influences the rapidity of reaction is social position. Persons of a lower grade have a longer reaction-period and greater differences than those in higher position, because they (especially the men) are less in the habit of attending to their own psychical processes. To do away with reflex action entirely, and to examine the reaction of the upper brain-centre purely, *e.g.*, consciousness, attention, will, the coloured papers were used. All colours are not perceived with equal rapidity; naturally, strong colours are quickest noted, and red sooner than yellow and white. The instrument can be applied

to the insane, and he gives tables of twenty persons, two women and eighteen men. The chief points to determine are, whether in many forms of brain-disease the transference of a sensory impression to a motor-nerve is delayed or hastened, and what and how constant is the retarding power which the insane can exert? Is a sinking of the reaction-period below the normal to be proved in certain conditions of exaltation? Experience is given of a person, aged twenty-four years, with large delusions, whose estimated period was 0.199 second, which is a higher number than that given by healthy men. It does not seem that the brain-capacity as regards rapidity of the course of psychic processes is directly lowered, but that the hallucinations and delusions manifest such a preponderance over the other processes that the attention is diverted and the reaction-period delayed nearly threefold. Other questions are gone into, but the results may be thus summarised.

1. In the insane, acceleration of the reaction-period is not proved.

2. There is always more or less prolongation of the reaction-period in the insane, shown either as an increase of the medium period, or directly caused by a rise in the minimum.

3. A rise in the minimum time denotes a deep-seated lesion in the brain; and, though not demonstrable in primary forms, was easily so in conditions of debility.

4. Rise in the medium period, conjoined with great differences among the single reaction-details, is a sign of loss of power of concentrating the attention, or of the preponderance of other mental conditions.

5. The course of the disease is characterised by changes in the reaction-period.

6. Both the prolongation of the period and the great differences between the separate experiments point to a diminished susceptibility of the brain, which can be easily expressed in figures.

T. CLAYE SHAW, M.D.

COMPARATIVE PATHOLOGY.

LEUCOCYTHÆMIA IN DOMESTIC ANIMALS. BY PROFESSOR O. BOLLINGER OF ZÜRICH.*

(Concluded from page 321.)

In contrast to the result of the above-mentioned inoculations, I believe that leucocythæmia in the dog, considered in one direction, tends to confirm Virchow's opinion as to the origin and spread of the disease. In the spleens of dogs, there occur with unusual frequency—according to my observations, made alike on healthy and on diseased animals, in at least ten per cent. of all dogs—true lymphomata. It is extremely probable that these form the starting-point of leucocythæmia: in the case already related, the splenic nodules were certainly present at the beginning of the disease. In confirmation of this assumption, I can bring forward a second case observed in a dog, affording an instance of leucocythæmia in the incipient stage, which rarely comes under observation.

2. A very large old male dog was brought to the veterinary school in this place to be killed. It did not show any special signs of disease, and shortly

before death ate abundantly with good appetite. The body was examined on May 6, 1871.

There were splenic leucocythæmia, and a large lymphoma of the spleen. The relation of the white to the red blood-corpuscles in the general circulation was 1 to 30 or 40; in the blood of the splenic vein, 1 to 10 or 15.

The animal was rather thin. The lungs were of normal extent, rather emphysematous, and strongly pigmented. On the left side were some subpleural hard bodies as large as pins' heads, which on microscopic examination were found to be bony deposits. The air-passages were normal. There was no remarkable change in the heart. Above the aortic valves, near the mouth of the coronary arteries, there was a prominence of the size of a lentil, with a rough surface, and mostly calcified: around it was distinct atheromatous thickening of the inner coat. On opening the abdominal cavity, a tumour nearly as large as a child's head was observed; it was covered by the great omentum, lay in front of the left kidney, and proceeded from the posterior surface of the upper part of the spleen. While the spleen itself was in other parts normal, containing little blood, of a pale flesh-red colour, and moderately firm, the tumour was of soft elastic consistence, of a shining dark violet aspect, with the peritoneal investment much distended and at several points closely adherent to the omentum. On section, the tumour was found to consist of a spleniform dark brown-red tissue of slight consistence, having embedded in it numerous deposits, mostly miliary, partly whitish, partly grey and diaphanous; they differed in no respect from the normal Malpighian bodies. In some parts towards the interior, these greyish white deposits predominated so much over the remaining tissue as to become confluent. On microscopic examination, the whole tumour showed all the elements of the normal spleen, but in place of the fine Malpighian bodies, there were large masses of lymphoid substance of similar structure. The spleen itself was remarkable for its great richness in granular blood-colouring matter and cells containing blood-corpuscles, as well as for a great amount of small and large fat-drops. The blood of the splenic vein was fluid, and of a clear red colour, and contained about one white corpuscle to ten or fifteen red ones. There was a slighter increase of the white corpuscles in the blood of the coronary veins of the heart, where the proportion was about one to thirty or forty. The liver was of a pale coffee colour, of normal size, and rather anæmic. The kidneys were of usual size; the capsule was easily removed, and on the surface beneath it were some cicatricial contractions. The substance of the kidneys was of a clear brown colour, and fragile; on microscopic examination, there was found to be marked fatty degeneration of the epithelium of the urinary tubules. The bladder was full of clear yellow urine, having a neutral reaction, and throwing down a flocculent deposit of albumen on being heated. On microscopic examination, instead of the cylinders that were expected, there were found numerous round nucleated cells, having the appearance of colourless blood-corpuscles, and a few spermatozoa. The mucous membrane of the bladder and urethra was normal. The stomach and intestine did not present any remarkable change. There was no enlargement of the lymphatic glands anywhere.

This case of simple splenic leucocythæmia, in which, besides the large lymphadenoma of the spleen,

* Virchow's *Archiv*, Band lix. Hefte 3 and 4.

there was only a moderate increase of the colourless blood-corpuscles, can without doubt, be applied in the direction indicated above. The disease was seized in its early stage, before it had gone on to metastasis, and to leucocythæmic disease of other organs. The remarkable amount of colourless blood-corpuscles in the urine, while the urinary passages were in a normal state, may perhaps be attributed to escape of the too abundantly formed cells into the diseased renal tissue; yet the simultaneous occurrence of spermatozooids in the urine indicates that there might possibly have been another source for these cells.

A further case of lieno-lymphatic leucocythæmia in the dog has been observed by Siedamgrotzky of Dresden (*Bericht über das Veterinärwesen im Königreich Sachsen für das Jahr 1871*); so that, in all, three cases of leucocythæmia in the dog have been fully described. The essential features of the case referred to were the following.

A four-year old spaniel, which had suffered for some time from loss of appetite and from diarrhoea, died four days after admission into the veterinary hospital. A large firm tumour had been detected in the abdomen by palpation. At the necropsy, the spleen was found to weigh about 2½ lbs; it was much enlarged, and was covered with flat projections on the surface. All the lymphatic glands, especially the mesenteric, were remarkably enlarged; as were also the tonsils. The proportion of white to red corpuscles in the blood was 1 to 15. There were sanguineous effusions in the spleen, on the pericardium, in the mucous membrane of the tonsils, and on the gums.

Siedamgrotzky also describes a slight degree of lieno-lymphatic leucocythæmia as having been found in a cat which had died of internal hæmorrhage. There was remarkable hyperplasia of the lymphatic glands, and the spleen was doubled in size.

With regard to other animals, there are observations on the occurrence of leucocythæmia in pigs and horses, to which I will briefly refer.

In the pig, the following three cases have been described.

Leisering (*Bericht über das Veterinärwesen im Königreich Sachsen, 1865*) relates a case of leucocythæmia in a pig, whose spleen, liver, mesenteric glands and blood, showed corresponding changes. Further details are wanting respecting this case, which was the first observed, and was evidently one of lieno-lymphatic leucocythæmia. Fürstenberg (*Berliner Klinische Wochenschrift, 1870*) describes a case of leucocythæmia in a pig, with enlargement of all the lymphatic glands, the spleen, and the liver. The spleen was more than two pounds in weight; the liver, which was studded with leucocythæmic deposits, weighed more than eight pounds. There was deposition of white corpuscles in the marrow of the bones. The blood was of a clear chocolate colour; the white corpuscles were enormously increased, their proportion to the red being 2 to 1.

In the case of splenic leucocythæmia in the pig to which I referred at the beginning of this article, the spleen was much enlarged, weighing 3½ pounds. There was remarkable enlargement of the kidneys, with leucocythæmic infiltration and extensive hæmorrhages. Leucocythæmic deposits were found in the liver and lungs. There was increase of the white blood-corpuscles, their proportion to the red being 1 to 5. The blood was of a clear red colour and watery. Whether the lymphatic glands were

affected, could not be ascertained. Microscopic examination of the hardened organs gave the following result. The spleen was in a state of hyperplasia, and its tissue presented exactly the same characters as in splenic leucocythæmia in man. Besides the abundant deposit of lymph-cells, there were great increase and thickening of the normal elements of the spleen. In the lungs, the chief seat of the leucocythæmic proliferations was the connective tissue sheaths of the arteries and bronchial tubes. The liver not only showed a remarkable lymphoid deposit in the connective tissue between the acini, but also in the acini themselves there was so great a deposit of lymphoid cells, that their number exceeded that of the liver-cells. Finally, the kidneys were enlarged to more than double the normal size, and were studded with hæmorrhages; they contained so many lymph-cells that, under the microscope, the organ presented the appearance of a lymphatic gland, the remains of the normal kidney being discoverable at points only in the form of urinary tubules and Malpighian bodies.

A number of cases of leucocythæmia in the horse are recorded in literature; but I pass them over, as I have not been able to convince myself that they were cases of idiopathic leucocythæmia. In the meantime, they all might, with greater justice, be classed among those symptomatic and transient forms of leucocythæmia which, following Virchow, we designate leucocytosis. Considering the known irritability of the lymphatic system in the horse, and the corresponding liability in this animal to inflammatory affections of the lymphatic vessels and glands, it may be supposed that such leucocytoses, which consist in a temporary increase of the colourless blood-corpuscles, are of frequent occurrence; and this is indeed observed in a host of inflammatory and other diseases affecting the horse, such as glanders, farcy, &c. After large blood-lettings, the increase of white blood-corpuscles in the horse may go so far, that the coloured and colourless corpuscles appear nearly equal in number.

The cases above related establish the complete agreement of leucocythæmia in domestic animals, especially the dog and pig, with the disease in man. The simple splenic, as well as the lieno-lymphatic and myelogenic forms of leucocythæmia, are found in these animals. This agreement extends also to the leucocythæmic changes in the liver, kidney, and lungs, and to the tendency to hæmorrhage. Hence it may be asserted that leucocythæmia, as observed in dogs, pigs, and cats, is identical with that of man; a fact which I can confirm by numerous observations on leucocythæmia in the human subject, which I was enabled to make under Buhl's direction in the pathological institute at Munich.

With regard to the etiology of leucocythæmia in man, it seems further to follow, from this agreement in character, that we must hesitate to accept as causes such conditions as syphilis, intermittent fever, &c., which certainly do not operate in animals. On the other hand, observation of the disease in domestic animals shows that certain causes of it are as yet completely hidden from our knowledge.

PATHOLOGY.

NOTHNAGEL AND OTHERS ON PRIMARY LESIONS OF THE ENCEPHALON AND CONSECUTIVE LESIONS OF THE LUNGS.—The study of the influence exer-

cised by the lesions of the nervous system, and in particular of the encephalon, in the production of secondary lesions in the lungs, is again attracting attention in consequence of a paper by M. Nothnagel and some facts communicated by MM. Baréty and Ollivier to the Parisian Society of Biology, and reported in the *Progrès Médical* of May 2. M. Nothnagel thus summarises his experience. 'When a certain tract of the upper surface of the brain of a rabbit, in the vicinity of the superior fissure there situated is wounded, if it be only with a needle, special disturbances ensue, especially interstitial pulmonary hæmorrhages, often so abundant as to fill the entire lung.' Dr. Brown-Séquard has observed something of an analogous nature: but after lesion of the base, and not of the upper surface of the brain.

M. Baréty has related a case in no. 17 of the *Progrès Médical*, which approximates to a certain extent to M. Nothnagel's experiment, in so far that there was meningeal hæmorrhage filling the convex surface of the right hemisphere on the one hand, and on the other congestion and subpleural and parenchymatous apoplexy of the left lung.

Cases, however, of this kind, by reason of injury of so serious a nature as to cause sudden death, have not the interest attaching to facts observed during a longer or shorter space of time, relating to spontaneous lesions, such as hæmorrhage or softening of the brain. Hypothetical as it is in relation to facts of the first-named order, the pathogenic influence of the encephalic focus can scarcely be disputed in regard to the second.

M. Ollivier relates, in no. 16 of the *Progrès Médical*, the history of a patient who succumbed to hæmorrhage of the right corpus striatum, with ventricular effusion, and hæmorrhage in the pons Varolii. In this case there was 'a noticeable amount of pulmonary congestion.'

An account of the history of this question was given last year in the *Progrès Médical* for 1873, p. 65. The experiments of Dr. Brown-Séquard were there mentioned. They show that lesions of the base of the encephalon, and especially of the pons Varolii in the neighbourhood of the median peduncles of the cerebellum, were accompanied by pulmonary hæmorrhages. Finally, after having affirmed that different writers, as Rostan, Cruveilhier, &c., had in their works given prominence to the frequent occurrence of pulmonary affections in diseases of the encephalon, stress was laid on a particular point, viz., that M. Charcot had added to those hitherto scattered inco-ordinate facts other facts observed with great care, and that he had for the first time grouped and interpreted them in his lectures on trophic disturbances. Since that time the researches which have been published, from those of Mr. Smith* to the more recent ones of MM. Baréty and Ollivier are interesting from various reasons, and help to confirm the ideas put forth and developed by M. Charcot. Now, however, that the facts are numerous and that the relation between cerebral and pulmonary lesions is well established, it is to be desired that observers should only bring forward precise and well-considered facts, and should not content themselves with details of a more or less precise nature. It is likewise important that lesions which, properly

speaking, are only concomitant changes, or even lesions which have no relation with lesions of the encephalon, should not be confounded with lesions of this nature.

LEOPOLD ON THE CHANGES OF FORM IN THE PELVIS THROUGH CONGENITAL OR ACQUIRED DISLOCATION OF THE THIGH.—Dr. Leopold (*Archiv für Gynæcologie*, vol. 3), was able to study the changes which occur in the form of the pelvis through luxation of the hip-joint, first in the case of the pelvis of a girl half a year old who died of marasmus, with congenital dislocation of the hip-joint, and secondly, by the careful investigation of several specimens of this form of pelvis (called by him 'luxation pelvis') which he found in the pathological and anatomical museum in Leipzig. By a careful study and comparison of these pelvises with the cases already described, the author finds that a congenital unilateral dislocation of the hip-joint produces quite another effect on the pelvis in relation to the position of the sacrum, lower lumbar vertebræ, and of the symphysis pubis, as well as in the size of the half of the pelvis on the luxated side, compared with the effects of an acquired unilateral dislocation of the thigh, differences which till now have not been clearly pointed out. Of course, whether the limb had been used or not before and after the luxation must make a difference.

In the chapter on congenital luxation, Dr. Leopold describes the pelvis (with luxation on the left side) of a girl half a year old, who of course had not walked, and the following are his chief results.

1. The sacrum tended towards the left side (dislocated side).
2. The left ilium was as large as the right, but was placed more vertically.
3. The left pubic arch was shorter than the right.
4. The left acetabulum was shorter than the right; in consequence, the parts of the pelvis on the left side were more compressed together.
5. The symphysis pubis was directly in front of the promontory.
6. The left half of the pelvis (luxated side) was *in toto* the narrower, the whole pelvis was asymmetrical, not displaced, but completely inequilateral.

With this pelvis the author compares the pelvis of a grown-up person, who had also congenital lateral dislocation of the hip on the left side, and who had used the extremities for walking. Resemblances were detected in the tendency of the sacrum towards the luxated side; differences, however, in the widening of the half of the pelvis of the affected side, through use of the limbs.

In the second chapter, unilateral acquired luxation and its effects on the pelvis are treated of, both when the limbs have been used for walking and when they have not been so employed, whether the patient at the occurrence of the luxation was young or grown up. He describes and figures amongst others two new and very interesting pelvises, the one with coxitis of the left acetabulum, consecutive luxation of the left thigh backwards, ankylosis of the right hip-joint, and probably ankylosis of the right sacro-iliac symphysis, and the other with right-sided luxation, and extensive rachitis in a young person. The latter pelvis showed, through the luxation, a pronounced oblique displacement and oblique narrowing.

After comparing the collective peculiarities of the pelvises with congenital and acquired luxation, he arrives

* 'De la Valeur pathogénique des Maladies cérébrales au point de vue des Affections pulmonaires.' (*Journal de Médecine de Bruxelles*, 1871, tome liii.).

at the following results and important points of difference.

1. The congenital, as well as the acquired luxation, produces distinct change in the pelvis, according as the limbs have been used for walking or not, whether the individual was young or old on acquiring the luxation, and whether the luxation was occasioned by accident or by inflammation. In each case luxation produces strongly pronounced changes. These are, however, different in the congenital and in the acquired luxation. In the former case, the changes vary according as the limbs have been used or not. It is quite the same in the acquired case; but here it depends materially upon whether the luxation happened before or after complete ossification of the pelvis.

2. In all pelves in common, the atrophy is of the luxated half. The use of the limbs increases in all cases the transverse diameter of the outlet and inlet of the pelvis. Non-use makes the inlet narrower in young pelves with congenital luxation; in the other pelves the inlet is made wider. The outlet is always narrower.

3. The sacrum tends in the acquired luxation towards the luxated side, whether the lower extremities have been used later or not. Quite the same in the acquired form when the accident occurs early, then a high degree of atrophy occurs if the legs have not been used. In all other cases the sacrum tends towards the sound side, but remains tolerably straight, according to the occurrence of the luxation and the use of the extremities. The want of symmetry of the sacrum is directed according to the degree of atrophy, either according to the natural disposition, by pronounced retardation in development, or by pressure and counter-pressure of the body-weight.

4. The pelvic half on the luxated side is therefore narrower in a young pelvis with congenital luxation; the same occurs in young as well as in adult pelves, where the luxation has been acquired in youth, and no attempt has been made to walk; but in all other cases, on the contrary, it is wider.

5. The position of the symphysis pubis is different accordingly. If the luxation occur early, and no attempts at walking have been made, the symphysis pubis stands either directly in front of the promontory or it is moved towards the sound side. If the luxation occur after completion of the pelvis, and no attempts at walking have followed, the symphysis will, with the widening of the luxated side, be drawn a little towards the side. When, on the contrary, the extremities have been used, then it always inclines towards the affected side.

6. The acetabulum of the sound side, through use of the extremities, is pressed upwards and forwards, and more or less into the cavity of the pelvis; that of the luxated side more outwards, backwards, and downwards.

7. The form of the entire pelvis is inequilateral, and that either not displaced obliquely, or obliquely displaced but not narrowed obliquely, at least in a very slight degree, or pronouncedly obliquely displaced, and much narrowed obliquely. The finer differences between these latter forms of pelvis are to be found in the original.

WM. STIRLING, D.Sc., M.B.

in which Professor Guillery was called upon to visit a young girl labouring under retention of urine, her usual medical adviser, M. Grégoire, being at the time absent. Upon Dr. Guillery's arrival, a cyst, which the patient had just evacuated from her bladder, was presented to him. With the catheter, Dr. Guillery removed some turbid urine which, with the cyst and a small bone, was brought to Dr. Glüge by the patient's father. The urine did not contain any pus, but deposits of urate of soda. Dr. Guillery, who found in the cyst a completely urinous odour, entertained no doubt as to the tumour having been emitted by the urethra. There was no effusion of blood.

Dr. Glüge, however, had seen a tooth attached to a calculus in the bladder of a woman, who had been operated upon, and at whose necropsy a dermoid and hairy cyst of the ovary was found communicating with the bladder.* But I had never known a case of a cyst voided from the urethra. However, the details communicated to him by Dr. Grégoire, formerly a military surgeon, left him no longer any doubt.

In the evening of June 11, Dr. Glüge was requested to attend Mdle. M—, about thirty years of age, suffering under retention of urine. She was of a delicate constitution, but ordinarily of good health. She said that since morning she had been suffering much in the lower part of the belly, and was unable to pass any urine, save a few drops at a time, and by making great efforts; that in the few drops of urine that escaped there were little clots of blood. The hypogastrium was swollen and was painful when pressed. A vaginal examination barely permitted the introduction of the tip of the finger, in consequence of the existence of the hymen. The catheter drew off a quart of urine, opaque, but not containing any trace of blood, and the patient immediately felt relief.

On the morning of the 12th, she had not been able to pass any urine. The catheter brought off somewhat less urine, of the same aspect as before. In the evening, after some fruitless attempts to pass urine made by the patient, Dr. Glüge was called in. Catheterisation was this time less easy; the instrument passed through the canal with difficulty, as it had become very sensitive, probably from a swelling of the urethral mucous membrane.

On the 13th, the abdominal pain was more tolerable; the hypogastrium was less distended; she had a sensation of pressure in the urethra. Dr. Glüge recommended a sitz-bath, prolonged as much as possible. It was continued during four hours. After a lapse of about an hour and a half, the patient not being able to endure any longer the violent pains in the urethral canal, Dr. Guillery was sent for, in Dr. Glüge's absence. A short time before his arrival the patient had ejected the cyst by violent effort. From this moment the urine flowed naturally, and on June 17 the patient retained only the remembrance of her pain.

The cyst was ovoid; its width was about 3 centimètres, and its length 4½ centimètres; the thickness of the wall was from 2 to 3 centimètres. The surface was wrinkled, with a velvet-like covering, easily detached, and composed of polygonal cells, with

* In a remarkable case, described by Sentin (*Encyclop. des Sciences Médicales*, published by M. Marinus, Brussels, 1838, p. 307), the tooth was implanted in the calculus, of which it formed the nucleus.

GLÜGE AND DANZEL ON DERMOID AND HAIRY CYSTS EXPELLED FROM THE URETHRA AND RECTUM. — Dr. Glüge relates (*Bulletin de l'Académie Royale du Belgique*, tome iv. no. 6) a case

nuclei. Under this epidermic layer was seen the dermis, with its numerous follicles widely opened, from which projected long blond, sometimes brown hairs, of a perfect physiological structure, with bulb, cortical and central substance, and sebaceous glands attached to the sheath of the bulb. Their length was from 2 to 3 centimètres. The dermis consisted of a very dense connective tissue. No sudoriferous glands were found in the portions examined. The inner surface of the cyst was lined with a thin, smooth, serous membrane, formed of connective tissue, and covered with small, round cells. The small bone which the cavity contained was of lenticular form, of uneven, yellowish surface, its structure and consistency recalling those of cement. The nature of the liquid which the cyst contained could not be ascertained.

In conclusion, Dr. Glüge draws attention to two facts. There was no hair in the interior of the cyst, and no sebaceous matter. Usually it is in the interior of the dermoid cysts that the fine or fixed hairs are found. Evidently the cyst was formed by parasitic inclusion, like those observed in virgins at the age of puberty, and even in men. It is probable that some communication was established between the ovary and the bladder in this patient, through which the cyst made its way. He does not think that a case analogous to this exists in the annals of science.

At the recent meeting of the Surgical Congress in Berlin, Dr. Danzel, of Hamburg, exhibited a tumour which he had removed from the anterior aspect of the rectum, about three inches from the anus, in a woman aged twenty-five. The tumour was about the size and shape of a hen's egg, but rather more spherical. It was covered with skin of normal structure, and with long hair, which projected in a great tuft a couple of inches from the anus, presenting a most extraordinary appearance. Masses of hair were frequently discharged *per anum*, and on the patient first calling to see Dr. Danzel, she showed him one of these masses. He fancied she was malingering. The tumour was fibrous in structure, and contained two fully formed teeth.

WILLIAM MAC CORMAC.

BROCHIN ON THE HISTORY OF DROPSIES.—According to M. A. Brochin (*L'Union Médicale*, April, 1874), the definition of dropsies generally accepted is incomplete, and, adopting the views of Professor Sée, he would replace it by the following. Dropsy is a non-inflammatory (*i. e.*, non-neoplastic) process constituted by the accumulation in the natural cavities, or in the interstices of the connective tissue, of a liquid ordinarily serous, rarely sero-fibrinous. This definition includes three necessary conditions to characterise a dropsy—viz., 1, Its seat in the natural cavities and in the interstices of the cellular tissue; 2, The nature of the fluid; 3, The absence of inflammation. These three conditions are accepted by M. Brochin from which to demonstrate the mechanism and mode of formation of dropsies.

On this point, and as a *résumé*, Professor Sée admits three great classes of dropsies:—

1. Dropsies due to lesions of the solids (affections of the veins, affections of the heart).
2. Exosmotic dropsies (the exosmosis being due to subalbuminosis).
3. Neuro-vascular dropsies, comprising three groups:—*a.* Dropsies arising from cold; *b.* Dropsies due to scarlatina; *c.* Dropsies caused by atonic

dilatation of the vessels. (Very weighty objections can be and have been made to the teaching of Professor Sée on this subject.) WM. ALLINGHAM.

DISEASES OF CHILDREN.

ASHFIELD ON AN EPIDEMIC OF MORBUS BULLOSUS NEONATORUM.—Dr. Ashfield reports (*Archiv Gynaekol.* v. vol. i.) that an epidemic of morbus bullosus neonatorum occurred in the Lying-in Hospital at Leipzig, during the months of July, August, and September, of 1872. Its first appearance was in a premature child, the offspring of a badly nourished mother, but perfectly free from all traces of syphilis. It next attacked a healthy child sixteen days later; the children born between, escaping. The exceptions soon became fewer, until finally, every child born became affected. The mothers of the first two were the only weakly ones; the children varied much; some were remarkably healthy, others sickly. The fine children at first escaped, but when the epidemic was at its height all were equally liable. The eruptions never appeared before the second day nor later than the fourteenth day. It was thought that the infection took place at birth, and that the period of incubation was from three to four days. Until the eruption came out there was no elevation of temperature, nor any signs of malaise. It began as a rule, in the neck or groins, spreading to the head, face, and belly. Its duration, with few exceptions, was from one to fifteen days. The bullæ increased in size very rapidly; one, of the size of a pin's head in the morning would be as large as a sixpence in the evening; some were larger than a crown. The abdomen and thighs were the seats of the largest. No parts seemed exempt, except the palms of the hands and the soles of the feet. There was slight fever when the eruption was out, and it was not unfrequently accompanied by ophthalmia. No cases were fatal. Only one mother was attacked with a like affection; she had pyæmia. A similar epidemic occurred in the city and the environs. The author believes it to be contagious, and dependent upon some miasmatic germ. He discards the name of pemphigus, as that disease is invariably connected with some constitutional affection. W. C. GRIGG, M.D.

PONCET ON OSSEOUS LESIONS IN INFANTILE SYPHILIS.—Dr. A. Poncet (*Progrès Médicale*, 1874, p. 237) gives details of the post mortem examination of twelve syphilitic infants. In nine cases the bones were found to be diseased in the special manner which was pointed out by Wegner, some years ago. In an early number of the LONDON MEDICAL RECORD there was a full account of the observations of Wegner, Parrot, Waldeyer, and others. Poncet's investigations do no more than confirm the results already obtained. SAMUEL GEE, M.D.

SURGERY.

SPANTIGATI ON ELASTIC COMPRESSION.—In a communication made to the Turin Academy of Medicine and Surgery, on March 6, 1874, Dr. Spantigati (*Giornale della Reale Accademia di Medi-*

cina di Torino, 20 Marzo, 1874) refers to Dr. Grandesso Silvestri's claim to be the originator of the use of elastic compression in surgery, which he seems to consider established. He then gives an account of four cases, in two of which immediate amputation of a limb was performed. The first was a man aged fifty-seven, who had received a wound in the lower part of the left arm from a weapon loaded with shot, and accidentally discharged at a very short range. The entrance-wound was comparatively small, and situated at a short distance above the internal condyle; about two inches above the external condyle there was an enormous laceration, on the posterior and outer aspect of the arm. The bone was broken into many fragments, while the muscles, nerves, and vessels, were much lacerated. The patient was collapsed and also under the influence of alcohol, to the use of which he was addicted. It was deemed advisable to postpone amputation till the following morning. The elastic bandage was not applied over the lacerated structures; the elastic tube was merely fastened round the arm, close to the axilla. Not two ounces of blood were lost during the operation. The patient, however, never rallied, and died some hours later of serous apoplexy.

The same night a young man, aged twenty-four, was admitted. His foot and leg had been crushed by a wheel. The ankle-joint was completely destroyed, and the bones of the leg and foot comminuted. It was deemed undesirable to make 'expulsive compression,' but the elastic tube was applied to the lower third of the thigh. The limb was then amputated through the upper third, and a very small amount of blood was lost. The patient remained prostrate during twenty-four hours, and then there was considerable reaction. Two days after the amputation gangrene appeared in the flaps, and spread as far as their bases. With the aid of antiseptic applications, the slough separated; and the patient finally recovered. The writer concludes that in cases like these, where the expulsive bandage cannot be used, the tube alone may, with advantage, be fastened round the limb.

The next case was that of a woman thirty-three years old, who fell on her right side in jumping a ditch, injuring the right ankle-joint. Some time afterwards, in descending a ladder, she again injured the foot; and not long afterwards she was admitted into the hospital with suppurative inflammation of the ankle-joint. There were abscesses, sinuses, and much thickening around the joint. It was determined to amputate the leg. An elastic bandage was applied from the toes up to the middle of the thigh, where the tube was fastened. The limb was then amputated by the circular method, without the loss of six drops of blood. The cartilages of incrustation had been removed from the surface of the ankle-joint, and the ligamentous structures softened. The tarsal joints were also diseased. The patient recovered quickly, and without any accident. The writer calls attention to the completeness of this hæmostatic means in amputations, and to the fact that expulsive compression may be safely used in cases where, as in this one, there are purulent collections. He does not apprehend any risk of introducing septic material or pus into the circulation; he believes this to be mechanically impossible.

The next case was that of a man aged thirty-seven. A year before, he noticed that one testicle had become larger than the other; and was seized with lancinating pains. Later an abscess formed, which

was opened. It did not heal, and when he was admitted a fungating mass, of the size of the fist, projected from it, with a large cavity in its centre, secreting a fœtid pus. The inguinal glands were not engaged, and the case appeared to be one of simple fungus of the testicle. An incision was made over the cord; the vas deferens and nerves were separated from the vessels, beneath which a silver probe was passed, and a piece of elastic thread tied over them, as in acupressure. The parts were now divided at a lower point, and the tumour removed. In this way, the inconvenience of tying the cord *en masse* was avoided. The ligature dropped off after three days, and the patient made a good recovery.

The author concludes that elastic compression is worthy of being retained as a powerful aid in the practice of surgery, and that great praise is due both to Dr. Grandesso Silvestri, who first proposed and practised the method in Italy, and to Dr. Esmarch, who diffused and more largely applied the method.

WILLIAM MAC CORMAC.

WOLFF ON RESECTION OF THE HIP-JOINT.—At a meeting of the Berlin Medical Society (reported *Berliner Klinische Wochenschrift*, Sept. 8, 1873) Dr. J. Wolff presented a little patient, three and a half years old, on whom, nine months before, he had performed excision of the hip-joint. The disease commenced when he was a year old; abscesses formed; the head of the bone became carious, and all the symptoms of advanced hip-disease manifested themselves. The operation was performed on December 16; the head and trochanter were removed; the acetabulum was rough, and its surface also required removal. A drainage-tube was then inserted, and the limb put up in gypsum with a wire splint, narrow opposite the wound, but broad enough to embrace the pelvis above, and the thigh and leg below, on the posterior aspect of the body. In front, the thigh and pelvic portions of the gypsum were subsequently united by an isthmus of wire. This splint was carefully shaped beforehand, so as accurately to fit the limb. The progress of the case was very satisfactory. At the end of six weeks the gypsum was removed, and Taylor's apparatus applied. Although the wound was not quite healed, the child was immediately able to stand, and, supported by the hands, to move about the room without pain. There was no appreciable shortening of the thigh. In some subsequent observations on the case, the author points out that in Leisrink's collection of 162 operations performed, on account of suppurative inflammation of the hip, the mortality was 63·6 per cent. This may be much diminished, Dr. Wolff thinks, by a more perfect method of after-treatment, and particularly by the application of a splint previously moulded accurately to the shape of the limb. In order to accomplish this satisfactorily, it is necessary to take a plaster cast of the parts. The writer expresses a strong preference for Langenbeck's method of operation, as by it the seat of the disease is readily reached, and drainage is amply provided for. A gypsum and a wire splint maintain perfect immobility of the limb in extension. After some weeks, when the wound begins to cicatrise, Dr. Wolff considers the use of Taylor's apparatus an improvement of immense value. It maintains the extension, and allows the patient to move about at a very early period; in the present instance, within two months after the operation. With reference to development of the bone; the

writer believes that the epiphysal cartilage does not anywhere play a great part, and that in the upper end of the femur it has absolutely no influence at all. It is known, for instance, that the trochanter minor remains throughout the development of the femur at the same relative distance from the head of the bone, which would not be the case if new bone were largely developed between the shaft and epiphysis. We may therefore, he thinks, more hopefully look forward to favourable results in our young patients in this operation of resection of the hip-joint, since every source of future growth of the upper femur has not been lost by removal of the epiphysal cartilage, as many writers have maintained, and many still maintain, but rather that the portion of bone still remaining, extending from the trochanter to the middle of the diaphysis, remains capable of the future development of the bone. We need not, in that case, look hopelessly forward to an ever increasing shortness of the extremity. Our appointed task is, by unremitting treatment, by strict superintendence, diligent exciting of the functions, and by every other means to forward and encourage the further growth of the upper thigh, seeing that the conditions necessary to such growth are still preserved.

WILLIAM MAC CORMAC.

MATERIA MEDICA AND THERAPEUTICS.

WALKER ON THE ICE-TREATMENT OF TIC DOULOUREUX.—Dr. B. M. Walker, of Plymouth, North Carolina (*American Quarterly Journal of Medical Science*, April, 1874.) says, in June, 1868, he was called to see a lady aged sixty, suffering with tic douloureux. She had been under the care of a very intelligent physician at a watering-place, who told her that he had exhausted all the resources of his science. Dr. Walker gave her quinia, iron, and strychnia, with a generous diet, and recommended the most agreeable society and mental employment possible; relying always upon the hypodermic use of morphia to obtain temporary relief, which was only temporary. This course of treatment was continued some time, and changed only when it appeared from habit to be losing its potency. This routine was kept up for five years, no remedies securing for the patient a longer period of relief than a few weeks, until he read in the *American Journal* (Jan. 1873), a case of tic douloureux treated by Dr. Winternitz with the local application of ice. Dr. Walker directed his patient to use the ice upon the part which was over the fifth pair of nerves, and advised the continuance of the application as long as she could bear it, at the same time holding brandy in her mouth. She described the pain as being more intolerable for a while than ever before, then it began to subside and perfect quiet was obtained. He directed her to make the application upon the slightest return of the pain, which he confidently expected to be about twenty-four hours from that time, as it was customary in her case to assume this periodical return. The pain did not occur the next day nor the day following; and there has not been the least return of the affection since.

VEYRIÈRES ON THE PHYSIOLOGICAL AND THERAPEUTIC ACTION OF NITRITE OF AMYL.—Dr. Vey-

rières, in his memoir on the nitrite of amyl (*Thèses de Paris*, no. 98, and *Bulletin Générale de Thérapeutique*) takes up the researches of Guthrie, Richardson, Gamgee, Lauder Brunton, Amez-Droz, &c., and studies the preparation and action of this new therapeutic agent, which is scarcely known in France.

The nitrite of amyl, discovered in 1844 by Balard, is obtained by causing nitric acid to act on amyl alcohol. After many trials, M. Veyrières advises the following method of preparation.

Take the amyl alcohol of commerce, wash it, distil and re-distil it, breaking up the products until there is a liquid having a fixed boiling-point of 132 degrees. To amyl alcohol thus purified, add a fourth part of nitric acid, shake it carefully, place a small portion of the mixture in a retort heated in the water-bath; as soon as it bubbles, extinguish the fire, and allow the reaction to finish it by itself.

Up to this point it is prudent to operate on a small quantity of liquid only, but in the following operations a much larger quantity may be treated. To distil the products of the preceding operation, a glass retort heated in the hot water bath and a receiver partially plunged into cold water are sufficient. Push the distillation as far as you like; at that temperature the formation of any amyl compounds need not be feared. Take the product of this distillation, add to it 1 gramme of caustic potash to 20 grammes of the liquid; keep it in view for some hours, shaking it from time to time, decant the top, distil it by the same process as before. Two layers will be found in the receiver; the lower white layer will be divided from the upper yellowish layer, which is composed of pure nitrite of amyl. A liquid having a density of 0.87 degrees, of which the boiling point is 99 degrees, is thus obtained. This is the nitrite of amyl ($C^{10} H^{11} N^2 O^4$) which diffuses a vapour having a decided odour of apples.

When two drops of nitrite of amyl are inhaled, the pulse for some minutes becomes accelerated to 110 beats; the pulsations of the heart become rapid; the face becomes highly flushed. These symptoms are transitory, and disappear rapidly when inhalation ceases.

In the lower animals the nitrite of amyl produces acceleration of the heart-beats, due, according to M. Amez-Droz, to a diminution of the arterial tension and a sideration of the nervous system. When the dose given to a dog exceeds forty or fifty drops, death may supervene with convulsive phenomena.

Nitrite of amyl has been employed as a therapeutic agent in angina pectoris, in cases of asystole, lipothymia, etc., but the facts are not sufficiently numerous to afford very precise indications. The nitrite of amyl should always be employed in doses of from four to ten drops.

HURD ON INSOMNIA IN INFANTS.—Dr. E. P. Hurd, of Newburyport, Massachusetts (*Boston Med. and Surg. Journal*, February 5), states that he has found chloral-hydrate especially useful in the insomnia of infants. One grain may be given to a restless infant every hour till sleep is induced. Gelseminum admirably fulfils many of the requirements of a hypnotic, for its action seems to be largely that of an exalter of sympathetic function, and it lessens cerebral congestion. Three drops of tincture of gelseminum, with three of laudanum and ten grains of bromide of potassium, every two hours, have suc-

ceeded in breaking up insomnia when other remedies have failed.

MORIN ON A NEW COUPLE FOR THERAPEUTIC APPLICATIONS.—M. Morin has described to the Academy of Sciences of Paris a new battery he has had in successful application for several months. The construction is arranged with the view of obtaining a constant battery of higher electromotive force than the Daniell. The arrangement consists simply in surrounding the central carbon with a solid chromic salt, which is dissolved by the water of the zinc bath. The salt represents the chemical constitution (less water) of Jacobi's solution.

PUBLIC HEALTH.

ON THE USE OF ZINCED OR GALVANISED IRON FOR THE STORAGE AND CONVEYANCE OF DRINKING-WATER. BY W. E. BOARDMAN, M.D., OF BOSTON.*

The Report of the State Board of Health of Massachusetts, for the year 1871, contains a paper upon 'Poisoning by Lead-Pipe,' which is confirmatory of the now well-recognised fact, as illustrated in the following paragraph (p. 40): 'From the evidence presented in the preceding pages, it seems reasonable to believe that the use of lead-pipe for the conveyance of drinking-water is always attended with a certain degree of danger, because such water always contains lead; and that this danger varies in degree with the character of the water conveyed and the susceptibility to lead poison of those who drink it.'

With the view of obviating the dangers arising from the use of lead-pipe, different methods and materials have been suggested from time to time. In this way, zined (or what is termed commonly galvanised) iron has come into use, and at the present time is extensively employed, both in this country and in Europe, for the purposes of roofing-material, gutters and conductors, reservoirs, water-conduits, bathing-tubs, cooking utensils, etc.

The object of the present paper is to determine, if possible, whether or not the employment of this material for the storage and conduction of drinking-water is attended with danger of zinc poisoning, as has been re-affirmed recently.†

The various modes of protecting iron, with the exception of mere superficial coverings, have all been of the electro-chemical class, and have been derived, in various ways, from suggestions deduced from the experiments and observations of Sir Humphry Davy,‡ for the protection of the copper sheathing of vessels. In his paper on this subject, the author developed the principle of counteracting chemical by electrical forces. Subsequently his idea was adapted

to particular cases. He stated that it follows from the principles which he developed, that cast or wrought iron may be preserved from chemical action by suitable protectors of zinc or tin. Professor Edmund Davy was the first to publish* a series of experiments which he undertook with the view of determining this protective power of zinc, which he employed in simple contact and in massive form. Shortly after the publication of the results of these experiments by Professor Davy, M. Sorel, a French engineer, obtained a patent for the protection of iron against rust by coating its surface with fluid zinc, and, with this patent, the first manufactories of zined or galvanised iron were established in London, under the style of the 'British Galvanisation of Metals Company,' and the 'Zined or Galvanised Iron Company.' Professor E. Davy, however, claiming priority of discovery, stated that he had employed this method of zining iron so far back as 1834, yet we have no other record of such experience than his simple statement. Without knowledge of the principle, however, Madame Leroi de Jan-court was granted a patent on September 26, 1791 for preserving metals from rust by covering them with an alloy of zinc, bismuth, and tin.

Zined or galvanised iron is prepared by dipping the iron, previously well cleaned by means of dilute acid, into melted zinc. By this process, the iron becomes superficially combined with the zinc, and there is furnished, as claimed by the first manufacturers, a material which is adapted for use as water-pipes, reservoirs, etc., is durable, cheap, and is unattended with danger to the human system in the way that lead is when employed for similar purposes.

In order to discuss connectedly and to the best advantage the subject which we have in view, it has been deemed advisable to consider it under the following heads, viz.—

1. Is the zinc of galvanised iron acted upon by water, and what are the products of such action?
2. Do these products exert a poisonous action upon the human system?

1. The action of water upon zinc has been recognised for a long time. In the year 1778, M. de la Falie, a French physician and chemist, in place of vessels of iron, copper, &c., then employed for culinary purposes, proposed the use of iron vessels lined with zinc, principally upon three grounds: namely, because, in his opinion, the zinc would not be dangerous; such vessels would not be very expensive, and they would be more durable.† A subsequent report to the French Academy of Sciences disapproved of the use of these vessels, on the ground that the zinc is removed and endangers the health. Discoveries of new sources of supply of the metal and of the means of rendering it more useful in the arts, led to the revival of its employment, by MM. Douey and Montagnac, in the manufacture of culinary articles, roofing materials, reservoirs, water-conduits, &c. The first petitions of these gentlemen to the proper authorities having been reported upon unfavourably, by MM. Thenard and Gay-Lussac,‡ they made another petition which led to a series of experiments by MM. Vauquelin and Deyeux,§ under the authority of the Academy of Sciences. In their report they state that zinc is acted upon by water,

the weakest vegetable acids, and butter; that water, allowed to stand in zinc vessels, was partly decomposed and a white oxide was produced, while the water covering the oxide had a metallic taste.

M. Schaufele* made a series of careful experiments, the results of which were confirmed later by distinguished chemists, notably by Payen and Chevallier,† with the view of determining the action of various substances upon zinc. He found that common water, allowed to stand in a galvanised iron vessel, presented traces, very slight indeed, of zinc at the expiration of thirteen hours; that common water, placed in pure zinc vessels, gave no indication of the presence of zinc; that distilled water showed traces of zinc, in five hours, both in pure zinc and galvanised iron vessels.

Similar results have been reported by numerous reliable observers. Professor Wm. Ripley Nichols, of the Massachusetts Institute of Technology, remarked to the writer that he always expects to find zinc in water which passes through galvanised iron pipes, and, in a written communication, he stated that a specimen of water drawn from the pipes, which have been in use in the Institute for eight or nine years, contained a small amount of zinc in suspension, and in solution an amount equal to 0.062 grain to the gallon. The water had remained undisturbed in the pipes for about thirty-six hours.

Another specimen of water was examined by Professor Nichols, at the request of the writer. It was spring-water which had passed through between forty and fifty feet of zinc pipe, from which no water was drawn previously for about twenty-four hours. The analysis gave rise to a suspicion of drainage contamination, and detected a trace of zinc in suspension and 0.843 grain to the gallon in solution.

This subject of the action of water on zinc has been most ably treated by Robert Mallet,‡ who drew up a series of papers showing the results of experiments made by himself, with the view of determining the best protector for iron against corrosion by air and water. Among the conclusions derived from his prolonged and carefully conducted experiments, the following may be quoted in proof of the affirmative of our question.

‘Of Cast-iron in Simple Contact with Zinc, immersed in Fresh Water.’

‘If cast-iron be perfectly free from any initial stains of rust and quite homogeneous in texture, it is electro-chemically preserved by an equal surface of pure zinc for an indefinite period, during which the zinc is oxidated, and forms mammillary concretions on the iron; after which the protective power of the zinc is greatly diminished, and, at this stage, the contact of any substance, even a neutral one—such as glass—with the iron, is sufficient to originate oxidation upon it.

‘If cast-iron, having a polished surface, is suffered to contract any coating of rust, although the surface be afterwards perfectly polished to the eye, yet zinc, in simple contact, has lost nearly the whole of its power of protection; the zinc and iron both oxidate from the moment of immersion.’

‘Of Cast-Iron, in Simple Contact with Zinc, immersed at an indefinitely small Depth in Fresh Water.’

‘Cast-iron, free from initial rust, so exposed in contact with an equal surface of zinc, is oxidised from the first moment of exposure. The zinc is oxidised from the first also.

‘A plate of iron, whose entire surface was covered with zinc in metallic contact [zincd or galvanised iron], was immersed for twenty-five months in fresh water. On examination, much flocculent zinc had been formed, and lay at the bottom of the glass vessel, which, in some places, was stained with red oxide of iron. The zinc surface was found, in irregularly scattered patches, wholly removed down to the iron, which was covered with peroxide. Hence, about two years appears to be the limit of the preservative power of zinc to iron in fresh water, applied in fusion over its whole surface by the ordinary method. It is to be observed that the zinc surface was removed by solution, unequally or in patches, indicating local action *ab initio*; and it has been shown before that as soon as oxidation takes place at any point upon the iron surface, the protective power of the zinc is diminished at once or rendered null. [The corrosion of both zinc and iron then ensues more rapidly.]

‘The conditions the most favourable possible for rapid oxidation of iron consist in its exposure to wet and dry or to air covered with an indefinitely thin film of water, constantly renewed; thus circumstanced, zinc has no protective power over iron in fresh water, and, on the whole, it may be affirmed that, under all circumstances, zinc has not yet been so applied to iron to rank as an electro-chemical protector towards it, in the strict sense.’

In a report,* made by Professor Max Pettenkofer, in reply to the inquiry, how thick a covering of zinc is required to insure permanent protection against the oxidation of iron, the author gives the results of a series of experiments, undertaken by himself, with zinc plate taken from the roof of a building in Munich, where it had been exposed to the atmospheric influences during twenty-seven years. The outer surface was found to be covered with a thick, whitish, oxidized layer, of varying depth, showing that the oxidation had followed the crystalline structure of the metal. By calculation, he determined approximatively, that upon a piece of the zinc, one and a half feet square, there were present 4.264 grammes of zinc rust. By experiment, also, he estimated the amount which had been removed during these twenty-seven years, in the rain-water, in solution and by mechanical displacement, as about 4.117 grammes, making a total of 8.381 grammes.

The preceding observations, which have been made at different periods, and were derived from a variety of sources, will be sufficient to illustrate the fact that the zinc of galvanised iron is acted upon by water; that, when allowed to stand in reservoirs or to flow through pipes of this material, water will contain a greater or less amount of zinc, for a longer or shorter period; finally, that, sooner or later, the whole of the zinc will be removed.

(To be continued.)

PROPOSED REGULATIONS AS TO THE STORING OF CHEMICALS IN THE METROPOLIS.—The follow-

* *Jour. de Chim. Méd.* t. iv. p. 663, 1848, and Tardieu, *Dict. d'Hyg. Publique*, t. 3, p. 708. 1854.

† Tardieu, loc. cit.

* *Abhandlungen des naturwissenschaftlich-technischen Commission in München*, vol. i. 1857.

ing clause occurs in the Metropolitan Buildings and Management Bill, which has been introduced into the House of Commons by Colonel Hogg, the Chairman of the Metropolitan Board of Works.

'29. It shall not be lawful for any person to deliver, receive, or keep any quantity greater than that from time to time prescribed by bye-law of the Board under this Act of any of the following articles, namely—petroleum, phosphorus, mineral oil, turpentine, resin, tar, pitch, paraffin, naphtha, varnish, fireworks, matches, sulphuric acid or other mineral acid, or chemicals of an inflammable nature, into or in any building other than a fire-resisting building, or a cellar, or a room on the basement storey of a building, or a room on the ground storey of a building having a cellar or vault immediately under it, covered with such arching as is required for support of floors in fire-resisting buildings.

'It shall not be lawful for any person to deliver, receive, or keep, any quantity exceeding *half a ton* of saltpetre or nitrate of soda into or in any building other than a building approved by the Board as fit for that purpose; in which case no goods other than saltpetre or nitrate of soda shall be delivered, received, or kept, into or in the same building.

'If any person acts in any manner in contravention of this section, he shall be deemed guilty of an offence against this Act, and shall for every such offence be liable, on summary conviction before a magistrate, to a penalty not exceeding *fifty pounds*, and to a further penalty not exceeding *twenty pounds* for every day on which the offence continues after notice thereof served on him by the Board.'

EPIDEMIOLOGY.

ERMAN ON THE CHOLERA EPIDEMIC OF 1873 IN HAMBURG.—In Virchow's *Archiv*, vol. ix. part i. Dr. Fr. Erman communicates some interesting observations on the cholera patients in the General Hospital in Hamburg, of whom there were about 260 from the middle of June to the beginning of October, 1873. When the epidemic commenced, the only other parts of Germany known to be infected were some places on the Vistula. Till the middle of July the cases came in, one by one, and all from one spot. At the beginning of August they began to be more numerous and more diffused. At the end of October the epidemic was over. From June 16th to July 30th there were 21 cases, during August 172, in September 71, and in October 11; in all 275. The ten last patients were emigrants, attacked on board ship. Eight of the 274 were inmates of the hospital; and the mode of contagion is noteworthy. All had either occupation amongst the cholera patients (as nurses or porters), or were in wards closely contiguous to the cholera-wards. Thus the female cholera patients were at first in Room No. 386 of the new building, and the first inmate attacked was one in Room 384, which had two doors—one into No. 386, which was closed, and one which opened into a common corridor. The next was a porter who had to carry corpses to the dead-house, and had washed one after a post mortem examination. He had only left the house once for the last fourteen days before his death, and then went to a neighbourhood where no cholera cases occurred until some weeks later. Four weeks afterwards a patient, aged fifty-eight, was attacked, who was an inmate of

Room 401, into which, three hours before his attack, a cholera patient had been carried by mistake. Next a male nurse, and then an ironer in one of the laundries, who had not to wash any of the cholera linen. After this another male nurse was attacked. The next patients were four children, from a room close to the female cholera ward, one of whom was probably the carrier of contagion to the others, having been sent for supposed cholera into the special ward, and sent back. He ultimately died of the disease. As only 8 out of a community of 1500 persons were attacked, and those 8 were thus exposed, we can scarcely deny contagion. It is however remarkable, that in 1848, when there were no special cholera wards, and the dejections were kept for the doctors' inspection without any disinfection, although cholera cases were mixed with other sick people, only a few isolated cases occurred amongst the patients, and none amongst the nurses or porters.

In 1859, during the second great epidemic at Hamburg, 400 cholera patients were under treatment in special wards, situate between the general ones—from the middle of June to the end of September. The only precautions were disinfection of the stools and closets with ferrous sulphate. None of the attendants were attacked, but 17 of the other patients were [see Tüngel's *Mittheilungen von der medium Abtheilung des Allgemeinen Krankenhauses zu Hamburg im Jahre 1859.*] Again in 1871 there was no spread amongst the inmates, although 70 patients with cholera were received.

There are some valuable remarks on temperature. The author thinks that Güterbock's cases (Virchow's *Archiv*, vol. xxxviii.) of temperature requiring forty-three minutes to reach its full height, may be differently explained. He never saw any appreciable difference between the reading at twelve minutes and that at fifteen minutes. It is only in the first few hours of the attack that there is any considerable difference between the axillary and rectal (or vaginal) temperatures. This difference soon begins to decrease by the rapid rising of the axillary temperature—and the defervescence is tolerably simultaneous, as regards the different points for measurement of temperature. The author calls all those cases febrile, in which the rectal or vaginal temperatures were 100.5° or more, and those in which there were only 96.8° to 100.4° he calls free from fever. Of the former there were 109, of the latter 117. In the febrile cases the rectal or vaginal temperature reached a height of 100.5° to 102.2° in 43 patients, of whom 9 were pulseless; 102.2° to 104° in 43 patients, of whom 29 were in the same pulseless state; 104° to 105.8° in 12, all but one pulseless; 105.8° to 107.6° in 11, ten of whom were pulseless. Thus 59 out of 109 febrile cases were pulseless, &c., whilst of the 117 without fever only 24 were pulseless. Thus 48.2 per cent. of the cholera cases had fever—and their mortality was 55.9 per cent.; whilst the cases free from fever had a mortality of only 38.4 per cent. Blood occurred in the stools in 11 cases; 9 of them in those free from fever. All died. Twelve patients had skin-affections as sequelæ (roseola and urticaria). Two suffered from consecutive boils. One had thrombosis of some veins of the right leg, below the knee. Two patients had long-continued mental disturbance—one was a backward youth aged twenty-three (whose testicles were no bigger than hazel-nuts) who was perfectly demented for three weeks. The second, who had injured his skull some years before, had melancholia. Several

patients were attacked with delirium tremens after their recovery from cholera.

As regards the pathology, Dr. Erman strongly insists, that in children fatal attacks of cholera frequently run their course with bile-colouring in the stools all through the attack; and the contents of the intestines and stomach were often anything but rice-water-like. Minute extravasations were common in the pleuræ, lungs, kidneys, and the walls of the heart, as well as in the endocardium and pericardium.

Güterbock observed that in adult males dying of cholera there was nearly always an emission of semen, which he ascribed to rigor mortis. The semen is found on the scrotum or in the groin, and the urethra is often full of spermatozoa. (Güterbock, *Bericht über die Cholera-station*, Berlin, 1852.) Rarely pure semen is found in the bladder itself. Very often the spermatozoa may be found lively even sixteen hours after death. Our author, whilst confirming these facts for cholera, insists that this phenomenon is not peculiar to this disease. He has examined some thirty corpses after other modes of death, and found semen in the urethra of all but one (who had been long confined to bed). Thus an emission occurs in patients dying from pneumonia, tetanus, delirium tremens, and other acute diseases, as well as after injuries. Of course there may be cases without any spermatozoa, just as in life. [Consult Casper on this point.] Casper and Lewin long ago established the fact that seminal fluid is found in the urethra of the great majority of male corpses, but did not determine the period at which the emission takes place, though Lewin (G. Lewin, *Studien über den Hoden: Deutsche Klinik*, 1861, no. 33), believes it to be a part of the rigor mortis. Without denying the possibility of this (for in cholera, especially post mortem, muscular movements are specially pronounced) the author remarks that in other diseases he has ocular proofs that this is often one of the phenomena of the death-agony, and occurs, generally without any erection or proper ejaculation, one or two minutes before the last breath is drawn. In one case, a youth of seventeen years, dying with opisthotonic convulsions, from caries of the petrous bone and abscess of the cerebellum, there was both erectio penis and ejaculatio seminis.

The treatment of this epidemic of cholera consisted mainly in tablespoonful doses of brandy or port wine, given hourly, with the freest use of ice and iced water. Subcutaneous injections of muriate of quinia in four to five grain doses were soon abandoned. The remaining treatment was almost all expectant. Troublesome hiccup was relieved in some cases by teaspoonful doses of common salt. The return of the pulse in one of his cases after abortion, is an interesting fact.

[The translator's notes of post mortem examinations, &c., enable him to confirm the remarks of the author as to the frequent occurrence of seminal emissions in articulo mortis in patients dying from other acute diseases, as well as in cholera.—*Rep.*]

W. BATHURST WOODMAN, M.D.

MCCANN ON SMALL-POX AND VACCINATION.—In his report to the Committee of the Small-pox Hospital at Stockwell, Mr. McCann states that, during the eleven months ending December 31, 1873, he had admitted eighty-one patients, of whom sixty-four had small-pox, and seventeen suffered from other diseases. Of the sixty-four small-pox cases, but one could be said to have been well vaccinated; eleven presented 'moderate marks,' and of these none died;

twenty-six presented 'bad marks,' and of these two died, or 7·6 per cent.; twenty-six had never been vaccinated at all, and of these thirteen died, or 50 per cent. The other diseases admitted to the hospital are classified as follows, viz., measles nine cases, nettle-rash four cases, scabies one case, chicken-pox one case, and venereal disease one case. 'Five patients,' Mr. McCann says, 'were received, who had been re-vaccinated; two of them two years, two eight months, and the fifth eight days before admission. In the first four cases vaccination was unsuccessful; and in the fifth, judging from local appearances, the operation was successful, but only in modifying the disease. One case came under treatment with a distinct second attack, the marks resulting from the first seizure being visible.' On December 29 the hospital was empty.

ALEX. COLLIE, M.D.

MACKELLAR ON FEVER.—From Dr. MacKellar's Report to the Committee of the Stockwell Fever Hospital, we learn that during the eleven months ending December 31, 1873, he admitted two hundred and twenty-six cases of typhus fever, one hundred and thirty-two cases of enteric fever, forty-six cases of scarlatina, and ninety-eight cases of other disease. Of the typhus cases fifty-six died (twenty-four males and thirty-two females), a mortality of 24·7 per cent.; which, however, by deducting the cases which died within forty-eight hours of admission, is reduced to 21·2 per cent. The danger from typhus in persons of advanced years is shown by the fact, that the mortality under thirty years of age was but 8 per cent., whilst that of persons over thirty years of age was 52 per cent. Of the enteric fever cases, twenty-four died, thirteen males and eleven females, being a mortality of 18·1 per cent., which is reduced to 16·2 per cent. by deducting the deaths which occurred within forty-eight hours of admission. Of the scarlatina cases, two died. Six cases of intermittent fever were admitted during the year from recognised ague districts in the country. These cases were not treated with immunity to the attendants, for Dr. MacKellar says: 'The chaplain, matron, four assistant nurses, and one male attendant' contracted typhus fever, one nurse enteric fever, and one nurse enteric and typhus fever. 'The chaplain and matron were both between fifty and sixty years of age, and both died.'

ALEX. COLLIE, M.D.

MISCELLANY.

THE number of medical students in the University of Strasburg during the winter session just past was 184.

PROFESSOR ESMARCH, of Kiel, has received permission from the German Emperor to wear the cross of the rank of Commander of the Royal Swedish Order of the North Star, second class, which has been conferred on him.

A NUMBER of cases of measles have lately occurred among the school children in several districts of Vienna, and there has been a marked increase of small-pox in one of the suburbs.

VACCINATION IN GERMANY.—It is reported in Berlin that it is intended to form in each province of the German empire a vaccine establishment, with the objects of providing medical practitioners with fresh lymph free of expense, and of undertaking and promoting scientific researches on vaccination.

PROFESSOR COHNHEIM, of Breslau, who has been suffering from illness, has recovered sufficiently to be able to return to his professional duties. Professor Pitha, of Vienna, has been obliged to visit Mentone and Meran for the benefit of his health. He is so far better that he expects to be able to return to Vienna in the autumn.

WATERING PLACES IN SPAIN. The Spanish Government has just issued an elaborate series of regulations regarding bathing and mineral-water establishments in Spain and the adjacent islands. The duties, rights, and privileges of the medical directors of these institutions are, *inter alia*, laid down with much minuteness.

MEDICATED LOZENGES.—Eighteen children were admitted last Friday at the London Hospital with severe vomiting, caused by eating 'medicated lozenges.' The facts are these. Some time since a confectioner's shop in the neighbourhood was burnt, and in clearing out the rubbish some was picked up and eaten by the children. Vomiting came on about four hours afterwards. Some of the cases were severe, but others were slight. Emetics and house medicine were given. None of the children were sufficiently ill for admission into the hospital. The lozenges were not sold, but were picked up by the children.

DISTRICT MEDICAL OFFICERS IN ITALY.—The project for holding a congress of Italian district medical officers at Forlì in September next is being pushed vigorously. Forms of adhesion have been circulated in the medical journals and otherwise; and the central committee have recently issued a manifesto, urgently recommending the appointment of local subcommittees. The prefect of Naples has recently issued a circular to the syndics in his province, asking for information on various points in regard to the medical service of the poor. In the course of the document, he remarks that there has been too much economy in the department, and that in consequence there has been a deficiency in the supply of well qualified medical practitioners for the poor.

HOW SMALL-POX IS SPREAD.—The following fatalities from small-pox are reported by the *North Devon Journal*. A boy of Combe Martin, an apprentice to a firm of drapers in Bristol, was lately taken ill, and sent to a medical gentleman, and almost immediately afterwards sent home by train, a telegram having been previously sent to his friends to send a conveyance to meet him at the railway station. It was a cold, raw day; and the parents, not supposing that their son was seriously ill, sent an open vehicle to bring him home. On his arriving at home, it was at once seen that the youth was suffering from small-pox. After a few days he died. The young man who fetched him from the station also took the disease and died, and the woman who nursed him is seriously ill. Two men who put the body into the coffin caught the infection, and one is reported dead. Another woman who took tea with the nurse likewise caught the disorder.

PARACELSUS ON THE NATURAL TREATMENT OF WOUNDS.—In an historical article just commenced in the *Allgemeine Wiener Medizinische Zeitung*, Dr. Rittman gives the following quotations from the writings of Paracelsus. 'Nature does not follow thee; thou must follow her.' 'In order that thou mayest understand what it is that heals a wound, know that the nature of flesh, of vessels, of bones, has in itself an innate balsam, which itself heals, wounds, stabs, and the like. The balsam that naturally lies in bones heals broken bones; the balsam that lies in the flesh heals flesh. Thus every surgeon should know that it is not he, but the balsam in the body, that heals. If the surgeon think that it is he who cures, he deceives himself, and does not know the measure of his own skill.' 'The surgeon is the protector of nature; and he can only perform this duty by having a knowledge of medicine.' The 'balsam' spoken of above (which in modern language we call plasma) takes, he says, its origin

from food and drink; but its healing effect is promoted by the skill of the physician. 'A wound must be kept clean and pure in its nourishment, so that nothing foul or stinking may be found in it. Know, that the pus in wounds is of two kinds; one proceeding from the nutrition of the wound, the other from corruption. . . . Keep wounds pure and clean, and protect them from external and accidental enemies. Thus are all wounds healed.'

LAUGHTER AS A MEDICINE.—A short time since, the *Sanitarian* reports, two individuals were lying in one room, very sick, one with brain-fever, and the other with an aggravated attack of mumps. They were so low that watchers were needed every night, and it was thought doubtful if the one sick of fever could recover. A gentleman was engaged to watch over-night, his duty being to waken the nurse whenever it became necessary to administer medicine. In the course of the night, both watcher and nurse fell asleep. The man with the mumps lay watching the clock, and saw that it was time to give the fever-patient his potion. He was unable to speak aloud, or to move any portion of his body except his arms, but, seizing a pillow, he managed to strike the watcher in the face with it. Thus suddenly awakened, the watcher sprang from his seat, falling to the floor, and awakened both the nurse and the fever-patient. The incident struck the sick men as very ludicrous, and they laughed heartily at it for some fifteen or twenty minutes. When the doctor came in the morning he found his patients vastly improved, and said he never knew so sudden a turn for the better. Now both are up and well. Who says laughter is not the best of medicines? And this reminds the writer of another case. A gentleman was suffering from an ulceration in the throat, which at length became so swollen that his life was despaired of. His household came to his bedside to bid him farewell. Each individual shook hands with the dying man, and then went away weeping. Last of all came a pet ape, and, shaking the man's hand, went away also with its hands over its eyes. It was so ludicrous a sight that the patient was forced to laugh, and laughed so heartily that the ulcer [? abscess] broke, and his life was saved.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S.W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JUNE 10, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

BEARD AND OTHERS ON THE TREATMENT OF HEMIPLEGIA.

At a late meeting of the New York Academy of Medicine (*New York Medical Record*), Dr. George M. Beard read a paper upon practical points relating to the treatment of hemiplegia.

The leading features of the paper were as follows.

Treatment should be begun early. In general (with regard to electric treatment) too strong currents have been used, and have been continued too long. Electricity is a sedative as well as a stimulant.

There is no need of producing another lesion of the brain by employing electricity. A galvanic current may be sent through the seat of the disease in the brain, and local applications may be made to the muscles when the effects of the lesions are manifested. The spinal cord becomes degenerated from lack of use, shown by stiffness of the muscles, &c.; hence the electric treatment should also be directed to the spinal cord. This is an important point. Recent experiments have shown that a galvanic current can be sent through the part in the brain where the lesion is supposed to exist. Outside of theory, the following are practical considerations of much importance.

1. The will of the patient should be enlisted to assist in the moving of the muscles, and he should throw all the cerebral force into the movement of a hand or foot. The rapidity of the recovery depends very much upon the organic will of the patient. The medical man can accomplish very much more by urging that will into resolute action.

2. The muscles should be relaxed at the time when the application of the current is made. This is accomplished by giving the muscles artificial support, by an assistant's hand or otherwise, while the current is being applied. A contraction can be obtained when the muscles are supported or placed in a relaxed condition, when it cannot otherwise be obtained. It is very beneficial to maintain the artificial support throughout the entire course of treatment. The apparatus of Dr. Van Bibber, or the India-rubber muscle of Dr. Sayre, may be employed for this purpose with advantage. Dr. Beard had found some difficulty in making easy attachments for the India-rubber muscle. It is desirable to have something which the patient can have adjusted, and can wear with comfort.

3. Dry or moist heat should be freely applied to the muscles and joints. Localised dry heat can be conveniently applied by means of clay tubes, which can be made of any shape or size desirable. The tubes can be heated in an oven, covered with a cloth when removed, and then the arm or leg can be inserted and permitted to remain for a number of

hours. This should be repeated once or twice a day. The use of this means is beneficial, from the fact that it improves muscular nutrition and the nutrition of the joints. It is especially beneficial in the treatment of the small muscles of the hand.

4. Passive movements, especially of the shoulder-joint, should be begun early and done very much more thoroughly than is customary in a majority of cases.

5. Massage can be applied to individual muscles. When this means is alone employed, it is not productive of very wonderful results. Indeed, the same, to a considerable extent, may be said of all these measures. They all may be adopted at once. It is like the farmer's pulling out a stump by attaching many horses at once, and not by hitching up one at a time, working him until he is exhausted, and then attaching another.

6. The use of food for the nerves and brain embraces cod-liver oil, phosphorus, &c. Strychnia, hypodermically used, is also very serviceable.

Dr. Andrews, of the State Lunatic Asylum at Utica, has given the following formula for preparing cod-liver oil, which disguises its taste.

| | |
|----------------------------------|---------|
| Yolk of eggs | no. iv. |
| Glycerine | 3j |
| Cod-liver oil | 3iv |
| Phosphoric acid dilute | 3ss |
| Sherry wine | 3ij |
| Essence of almonds | 3j |

The eggs and glycerine are first to be carefully triturated in a mortar, and while the trituration is continued add the oil, drop by drop. When this is done, the acid, wine, and essence may be added. The above is not the precise formula used at the asylum, but it is essentially the same. The manner of making the emulsion is the important feature. The amount of phosphorus can be varied to suit different cases, or other remedies may be added, such as arsenic, &c.

A number of cases were then cited, illustrative of the benefits which may be obtained by placing in practice the items of treatment mentioned.

Three things were noticed relative to prognosis.

1. There is a tendency in a majority of cases, which are not speedily fatal, to slow but spontaneous recovery up to a certain point. Cases, however, which are properly treated, will improve much more rapidly than if left to themselves.

2. In those cases where spontaneous recovery is evident, and will be carried on to a certain point, treatment should be carried along side by side with the spontaneous improvement, and not deferred until spontaneous improvement has done its work.

3. Prognosis in cases complicated with hysterical and nervous symptoms is better than in cases which are not so complicated. A hysterical nervous temperament seems to antagonise the effects of the disease. The nervous are easy to make sick and easy to make well, while the lymphatic are hard to make sick and hard to make well.

Dr. J. J. Mason criticised the portion of the paper with reference to the passage of a continuous galvanic current through the brain-substance. It was, he said, perhaps a measure worth trying; but for a measure to be indicated as properly belonging to measures to be adopted, it must have been tried in a sufficient number of cases, and have been followed by results which can be traced directly to the action of the remedy.

Dr. Neffel remarked that when there was apoplexy,

the cause was not a local but a general condition of the walls of the blood-vessels. This condition must be taken into consideration in the treatment. In certain cases, upon *post mortem* examination, the gross appearances of the brain remained unchanged, but the microscopic lesions would be found to be important, such as were connected with the perivascular spaces, &c. As a secondary effect of such lesions, there might be affection of the nervous elements and consequent atrophy, &c. It was further known that such lesions were produced by irregularities in the circulation, and these again were produced by affections of the vaso-motor system. It was also important to take these conditions into account in the treatment. He regarded the use of stimulants as bad. One of the best remedies, from his own experience, was the galvanic current passed through the brain and sympathetic. It must be used, however, with the greatest care. The current should be very mild. Arsenic was also a very important remedy; it had the power of preventing such congestions. From one to three drops of Fowler's solution should be given once or twice a day, and continued for a month or more.

It was important never to forget that the affection of the brain called forth a secondary affection of the spinal cord; hence the spinal cord should receive treatment at the same time, in order to prevent, as much as possible, those secondary degenerations.

Dr. Van Bibber cited a case in which the improvement which has taken place as the result of placing the muscles in a state of relaxation was much greater than could reasonably have been expected without the adoption of this measure. He also cited a case of ptosis, in which the lid was raised by a thin piece of India-rubber band attached to it by means of court plaster, and then covered with collodion, and the other extremity secured to the forehead in the same manner. The benefit which had accrued since the application of this simple device had been marked.

UPHAM ON CEREBRO-SPINAL MENINGITIS.

In the fifth Annual Report of the Massachusetts Board of Health for 1873, Dr. J. Baxter Upham gives his own experience, and the experience of other medical men, on the nature of cerebro-spinal meningitis.

The first reliable record of the disease, as seen in the epidemic form in Massachusetts, dates as far back as 1806, when, in the month of March of that year, there were nine cases, all of which proved fatal. From that time it appeared in various parts of the state in a more or less epidemic form. It prevailed in particular in the year 1810, and was reported on by Drs. James Jackson and John C. Warrington. These reporters stated that the disease was first seen in the town of Dana, where it commenced about the beginning of the year, 'but not in any considerable number of instances until the cold weather of the middle of January.' In the latter part of February it was heard of in the various towns in the county of Worcester. 'It was seen at Cambridgeport in the latter part of March, and at Lancaster in April. In the course of April and May a few cases occurred at Boston, and again in the counties of Worcester and Middlesex. During May it presented itself in Springfield, and had not subsided in the second week of June.' Almost nothing more is heard of the disease

until 1849, when Dr. Joseph Sargent, of Worcester, reported it as having appeared in the month of March of that year in the towns of Millbury and Sutton; but in this instance few cases were seen, and Dr. Sargent suggested for the first time the analogy of the disease with the so-called 'spotted fever.' It is next reported in the town of Becket, in Berkshire County, and Dr. Jackson stated that he had met with isolated cases since the epidemic of 1806-16. Since the appearance of the disease amongst the soldiers during the war, it has been observed in various parts of the state of Massachusetts. In 1865-6 Dr. Upham observed five cases in the Boston City Hospital, some of which originated there; and Dr. Page saw a considerable number of cases near the close of the war, at Gallop's Island, a military post at Boston harbour. From a report of a Committee of the Massachusetts Medical Society, it appears that in 1857 there were three cases; in 1858 twenty-seven cases; in 1859 three; in 1861 five; in 1862 five; in 1863 seven; in 1864 eighty-eight; in 1865 one hundred and sixteen, and in years not stated, twenty-six, making a total of 280 cases. From 1866 to 1871 Dr. Upham could not find any reliable account of the number of cases. Neither the state nor city registration reports rendered 'much assistance in this investigation.' In the former the term cerebro-spinal meningitis does not even appear, but Dr. Upham infers that the disease may be embraced within the term 'Cephalitis,' under which term all inflammatory affections of the brain and spinal cord appear to have been classed until 1872, when in the State Nosological Records 157 deaths were returned as having occurred from the disease in question, sixteen from 'spotted fever,' and two from 'black fever.' In the same year the Boston City Registrar reports sixty deaths; thirty-four males and twenty-six females—from this disease; and he further says that in 1867, when the disease 'was first distinctively reported to him under its present name,' there were seven deaths; in 1868 eight; in 1869 seven; in 1870 five; and in 1871 three.

In the early part of 1873, in consequence of the disease having appeared in the eastern part of the state in an epidemic form, the State Board of Health issued a circular to its correspondents requesting information as to the nature of the disease. Replies were received from 199 physicians, who give more or less information of 517 cases, and upon this information Dr. Upham's account of the epidemic of 1873 is based. The onset of the disease was for the most part sudden. The earlier symptoms were, pain in the head, felt mostly in the front, pain and tenderness along the spinal column, retraction of the head, delirium, convulsions, a rapid pulse, and a hot dry skin. As the disease advanced, these symptoms continued, the pain becoming less marked, whilst stiffness and rigidity of the muscles of the neck and lower jaw, with difficult deglutition, supervened. Towards its close there was insensibility, pallor, alternating with flushings of the face, slow feeble pulse, but sometimes also very rapid, strabismus with dilated and insensible pupils, hemiplegia, paralysis of the respiratory muscles and of the bladder. The duration of the disease varied considerably. Some were carried off in forty-eight hours, whilst others continued for three months. One case is recorded to have lasted but two hours, and another to have lasted for six months. The mortality of the present epidemic was about 44 per cent., which is

considered comparatively low, 60 and 70 per cent. being by no means uncommon. The treatment consisted in the administration of sedatives, such as morphia, chloral, bromide of potassium, and cannabis Indica, emetics, cathartics, and counter-irritants, with, so far as appears from the report, no good result. As a sequela, deaf-mutism has been observed. All ages, occupations, and nationalities were liable to be attacked; but the majority of the cases were in young persons. As regards sex, of 517 cases, 231 were reported as males and 208 as females; and in 78 the sex was not stated. The circumstances of the patients, 'whether easy or otherwise, were pretty evenly balanced.' The malady was most common in the spring months. Of 394 cases in which the date of the attack was definitely stated, ten began in January; twenty-five in February; eighty-four in March; one hundred and sixteen in April; ninety in May; thirty-seven in June; ten in July; eight in August; five in September; seven in October; one in November, and two in December. The first recorded case is dated January 6.

At the same time the disease prevailed among animals, such as horses, cows, hens, chickens, dogs, and cats. Of the *post mortem* appearances in the human subject, Dr. Upham simply says they are few and meagre. Of the appearances found *post mortem* in horses, he says (quoting from Dr. O. H. Flagg, a veterinary surgeon) that they were 'congestion of the psoas and iliac muscles, and also of the external lumbar and sacral muscles. The meninges of the posterior part of the spinal cord were inflamed, with a quantity of coloured fluid in the canal, the amount of which I was unable to measure. The vessels of the arachnoid were full to distension, and in spots this condition seemed to dip down into the cord itself. There were petechial spots extending over the dorsal portion of the cord. The kidneys were inflamed (or perhaps more properly, congested) and enlarged.'

Dr. Upham does not think that there is any definite connection between the disease in question and unsanitary conditions; and certainly, so far as the returns from the medical men from whose reports he quotes, show, it would appear that the disease prevailed almost equally under conditions sanitary and unsanitary. It is to be remarked on this head, however, that not only are laymen unqualified to detect unsanitary conditions, but few medical men are so qualified. For the investigation of this subject, those who know just enough of the matter to enable them to measure approximately their own ignorance, know that the whole subject is a very wide one, a very complicated one, and one which requires special training, and a large special experience to deal competently with it. The returns of Dr. Upham's correspondents appear to us meagre and unsatisfactory in the extreme. What possible enlightenment is to be gained from such descriptions of the sanitary conditions of localities as 'high and dry,' 'low and damp,' and 'I have observed nothing worthy of special remark'? We should further like to know in how many instances enteric fever, hæmorrhagic small-pox, typhus fever, scarlet fever, meningitis, delirium tremens, and acute miliary tuberculosis have been returned as cerebro-spinal meningitis? When we come to Dr. Upham's own personal observations, we find that definite unsanitary conditions predominate. Of seventy-four cases investigated by himself, in

forty-six there were obvious sanitary defects, the most common insanitary condition being dampness of soil. Speaking of Charlestown, he says the position of many cases 'which occurred in this city was obtained by our medical correspondent and marked down upon a map. They were in the main low and damp; were mostly upon made land, and near the water, with marked exceptions, however.' Dr. Wheeler, of Chelsea, reported that all, or nearly all, of the cases which had come to his knowledge occurred on the low marginal lands, where the soil is to a greater or less extent saturated with moisture. The same localities where they usually expect to find the majority of their cases in epidemics of typhoid, diarrhoea, &c.'

In the following Table, the percentage of deaths in each ward of the city of Boston is shown.

| WARD. | Population in 1870. | Deaths | Ratio per Thousand. |
|------------------------|---------------------|--------|---------------------|
| XIII. | 8,536 | 11 | 1'288 + |
| II. | 24,912 | 27 | 1'083 + |
| IV. | 10,216 | 11 | 1'077 - |
| XV. | 14,851 | 14 | '942 + |
| X. | 13,097 | 12 | '916 + |
| XIV. | 11,385 | 10 | '878 + |
| I. | 23,824 | 20 | '839 + |
| VIII. | 11,278 | 9 | '798 + |
| VII. | 28,921 | 22 | '761 - |
| XVI. | 12,259 | 9 | '734 + |
| III. | 14,990 | 10 | '666 + |
| XI. | 14,617 | 9 | '616 - |
| XII. | 19,880 | 12 | '604 - |
| VI. | 11,792 | 7 | '594 - |
| V. | 14,166 | 5 | '353 - |
| IX. | 14,142 | 3 | '212 + |
| Deer Island | 1,660 | 2 | — |
| City Hospital | — | 9 | — |
| Mass. General Hospital | — | 2 | — |
| Not stated | — | 8 | — |
| Total | 250,526 | 212 | — |

If now we take the three wards in which the fatality was greatest, and compare them as regards their sanitary condition, with those wards in which the mortality was least, we shall find that the mortality was far larger in unsanitary than in sanitary districts. Thus Dr. Upham describes Ward XIII. as situated in the south-easterly part of the old city proper, spreading out along the waters of the South Bay, and intersected with tidal streams. 'It lies low, and has for the most part no proper drainage.' Ward II. 'Comprises a segment of the north end, so called, the oldest part of the city; its semilunar outline bordering upon the Charles River and the harbour. Many portions of this ward have a densely crowded population.' Ward IV. is centrally situated. It includes Portland Street, with the numerous courts and alleys adjacent, which can hardly be said to revel in favorable hygienic surroundings; eastward it reaches to the harbour, and includes some of the most active business parts of the city.' Ward VI., one of the three wards in which the mortality is lowest, covers the more elevated part of the city. Ward IX. 'is situated between the Common and public garden.' It is largely bottomed on made lands, but lately reclaimed from the sea, and comprises some of the finest streets in the city. The artificially made portion of this ward was originally a dry gravelly bank.' Ward V. is not described in the report.

[From these facts and descriptions, it may be fairly

concluded that cerebro-spinal meningitis is chiefly dependent upon general unsanitary conditions.—*Rep.*

ALEX. COLLIE, M.D.

WEICHELBAUM ON EXTIRPATION OF THE TONGUE AFTER LIGATURE OF THE LINGUAL ARTERY.

Dr. Weichselbaum, assistant in the Klinik of Professor Podrazski, in Vienna, has an article on this subject in the *Wiener Medizinische Wochenschrift*, no. 42, 1873. The arrest of hæmorrhage in operations for cancer of the tongue is often most difficult. In order to readily reach the bleeding points, Syme and Sédillot divided the symphysis menti, and held the two halves of the jaw asunder. Regnoli made an incision from the chin to the hyoid bone, and then a second parallel to the margin of the jaw; the muscles and mucous membrane being divided, the tongue was drawn down through the wound. Billroth, having the same end in view (to facilitate the securing of the arteries), made an osteoplastic section, or cutting out of the middle portion of the lower jaw, a proceeding also strongly recommended by O. Weber, in cases where the disease is far back in the tongue. The objection to this is the difficulty of the subsequent union of the divided portion of the jaw. Czerny operated in 1870 in a case of cancer in the tongue on the left side. He first tied the left lingual artery, then extended the incision along the hyoid bone as far as its right lesser cornu, and afterwards made an incision from the chin to the hyoid bone; the soft parts were divided, the tongue drawn down through the wound, and the disease removed. Billroth has more recently operated without preliminary ligature of the lingual artery. He makes merely a curved incision along the border of the jaw, pulls down the tongue through the wound, and the disease, even when very far back, can be thoroughly removed, while the bleeding vessels can be securely tied. Bulow gave an account of nine cases operated upon in this way, five with success. There is but little damage done to the soft parts, the operation is efficient, and provision is made for the discharge of matter forwards in place of into the trachea.

A large number of surgeons have attempted to perform operations on the tongue bloodlessly, either through the use of the ligature, the *écraseur*, or the galvano-caustic noose; or by the preliminary ligature of one or both the lingual arteries. So far as the first three methods are concerned, they are at the present time almost completely, and, as the author thinks, properly abandoned. At the most, the galvanic cautery is very occasionally employed. All three are open to the objections that one cannot be certain whether all the disease has been removed, and that they do not offer absolute security against bleeding either during or after the operation. The writer mentions a case of secondary hæmorrhage which occurred in the practice of Professor Pitha. Nunneley, who advocates the use of the *écraseur*, saw the lingual artery spout in one of his five cases. Von Bruns has had bleeding after the use of the galvanic cautery. The use of the ligature is very objectionable, on account of the great swelling it produces, and the subsequent presence, in the mouth, of a mass of gangrenous tissue.

The preliminary ligature of the lingual artery reduces the hæmorrhage in operations on the tongue

to a minimum. The first occasion on which it was practised on account of extirpation of the tongue was by Flaubert, in 1833, and by Mirault, in 1835. The latter had the greatest difficulty in discovering the vessel. At the beginning of this century, however, Colomb tied the artery on account of aneurism. The operation was looked upon as so difficult that it was seldom undertaken by surgeons. Formerly the artery was sought for between its origin and the point where the posterior belly of the digastric crosses it. The author, however, prefers to look for it within the triangle formed by the two bellies of the muscle, and the lingual nerve running above and more superficial. In the first position, the artery is much deeper, covered by the hypoglossal nerve, and by several veins, which are liable to injury, while the superior thyroid and facial arteries arise rather close to it. The nerve, lying almost immediately over the artery, may be mistaken for it, and in any case it must be drawn aside. Sometimes the facial and lingual arteries arise by a common origin from the carotid; besides, it is undesirable to place a ligature so close to the parent trunk. These objections do not hold if the artery be exposed in the little triangle of Lesser, whose boundaries are those above mentioned. Here, close beneath the fibres of the hypoglossus muscle, the artery will certainly be found.

The steps of the operation are as follows. The incision through the skin should be made along the upper border of the hyoid bone, three or four centimètres long, and beginning a centimètre externally to the middle line. At the extreme angle a large vein is usually met with, and should be drawn aside. When the platysma is divided, the submaxillary gland appears; this must be drawn upwards after freeing its lower border; and then, just under its middle, may be seen the above mentioned triangle, bounded by the shining tendon of the digastricus below, and the hypoglossal nerve, running from below upwards and inwards superiorly. It must be borne in mind that in old people, in women, and in short-necked individuals, the submaxillary gland projects further downwards, and sometimes even covers the hyoid bone. Often the border of the mylo-hyoid muscle overlaps the triangle, and the hypoglossal nerve may also run very low down. In such cases these parts must be simply pulled aside, and on incising transversely the fibres of the hypoglossus muscle within the apex of the triangle, the artery will at once come into view. There is hardly any hæmorrhage except when the capsule of the gland is being divided. This method of operating has been employed by Hüter about five times, and attributed to him in the *Deutsche Zeitschrift für Chirurgie*, vol. i. p. 587, but the writer asserts that it was previously employed by Professor Podrazski, and that it is described in Pitha and Billroth's *Surgery* without reference to Hüter.

Dr. Weichselbaum then relates the history of four cases. The first was a gentleman aged forty-two years, suffering for six months from cancer of the posterior and middle thirds of the left side of the tongue, extending across the middle line. The lingual artery on both sides was tied without difficulty, further than that caused by the motions of the patient, who was only partially under the influence of chloroform. He felt so much exhausted that the amputation of the tongue had to be performed four hours later. Meanwhile the organ had become visibly collapsed, cooler, and of a bluish gray colour. The tongue was forcibly pulled quite out of the mouth, and transversely

divided with a scalpel behind the disease; the infiltrated parts in the floor of the mouth were also removed, and the operation completed without any loss of blood. On the ninth day the lingual ligatures separated, and in about a fortnight the wound in the tongue had cicatrised, and the power of swallowing was not interfered with, and the patient could speak much more plainly than before the operation. The disease, however, returned, but not in the same place, and the patient succumbed some months later.

The next patient was fifty years old, and the tongue-affection dated eight weeks before. It appeared without assignable cause with swelling, redness and pain in the left half of the tongue, increased flow of saliva, and difficulty of swallowing and mastication. After four days two vesicles appeared; then a fissure, and finally an ulcer. When he was admitted to the hospital, there was an ulcer with hard irregular edges, and the induration about its base extended beyond the middle line. On October 29, both the lingual arteries were tied; the tongue became somewhat collapsed and pale, and was immediately amputated behind the disease through the posterior third. The bleeding was very slight and chiefly venous; one small artery, however, spouted and required to be twisted. The wound of the tongue was united by sutures, that in the neck was left open. The parts quickly healed without accident. On November 30, however, the patient died from an attack of pneumonia. His power of speech had almost perfectly returned.

The next case was a man sixty-seven years old. In February, 1873, he injured his tongue with the sharp edge of a carious tooth. The tooth was extracted, but the sore did not heal. On April 19 he was admitted to the hospital. A cancerous mass, of the size of a walnut, excavated by a deep ulcer, with hard edges, occupied the left side of the tongue, reaching as far back as the anterior palatine arch. The infiltration passed the middle line of the tongue. On April 21 the left lingual artery was tied without difficulty. Four hours later the cancer was cut out with scissors, a couple of loops of thread being first inserted, with which to pull the organ forward. From the cut surface of the tongue only venous bleeding occurred. After the excision of the parts in the floor of the mouth, one small artery required ligature. The patient died two days later, with oedema of the glottis, and purulent infiltration of the cellular tissue of the neck.

The author has collected thirty-seven cases of removal of the tongue after preliminary ligature of the lingual artery, with six deaths, or 16 per cent; while of nine cases performed according to Billroth's osteoplastic method, four died, or 44 per cent. But the number of these last are too small to form a proper comparison. The author points out that the absence of bleeding in the mouth makes the boundaries of the disease much more easy to recognise during the operation. When the disease has extended into the floor of the mouth, the author prefers Billroth's submental method, as the parts can be thoroughly drawn out, and the bleeding points secured without much trouble. When the disease is confined to one half of the tongue, it is probably only necessary to secure the lingual on that side, since the branches of the ranine artery do not anastomose in the tongue with those of the opposite side.

WILLIAM MAC CORMAC.

REUMONT ON CONSTITUTIONAL SYPHILIS, AND ITS MIXED TREATMENT BY MINERAL WATERS AND MEDICINES.

The subjoined is mainly a condensed translation of a portion of an article by Dr. Reumont in Valentiner's recent *Handbook of Balneology*.

Syphilis is termed constitutional when, the incubation-stage of the syphilitic germs being past, a peculiar disturbance of the system and altered nutrition of it are marked by the appearance of a succession of localised products. These products have one general character, and under favourable circumstances transmit syphilis from one person to another.

The experience of the fact that there is a certain amount of regularity in the appearance of these products, has led to the division of the symptoms of the constitutional disease into secondary and tertiary; the first referable to the cutaneous and mucous surfaces, the second to the osseous system, to serous or fibrous membranes, and the parenchymatous organs. But Virchow and many others have shown that there is no regular sequence in the appearance of these phenomena; tertiary accidents sometimes occurring during the secondary period, and *vice versa*. Sigmond remarks that it is impossible to make any strictly scientific division; but for clinical purposes he recognises four stages of the disease. In the first (with which balneology has nothing to do), sores and indurations, along with infiltrations of neighbouring glands, show themselves locally within the first three to six weeks. In the second period, there are hyperæmia and exudations on the cutaneous and serous surfaces, accompanied by inflammation of many of the lymphatic glands, with erythema, papulæ, and varicella-like eruptions. This is between the seventh and twentieth weeks. In the third period, the so-called *gummy* exudations, the syphilomata, appear, bearing a close resemblance to tubercle. The length of this stage is uncertain. It seldom commences within six months of the primary infection, but it sometimes accompanies the stage last mentioned; it first attacks the skin and mucous membrane and the cellular tissue beneath them, but the deeper-seated organs are also frequently attacked. When the fourth period has arrived, the symptoms on the surface have usually disappeared; the condition of syphilitic cachexia is established, the whole nutrition is disturbed, the internal organs suffer from new formations, visceral syphilis is produced. There is much wasting away of life and strength, while hydræmic, anæmic, and at times leucæmic complications, with other forms of disease, such as tuberculosis, occur.

Virchow divides the local phenomena of syphilis into the slighter and the more severe. On the whole, the slighter are the earlier, and the more severe are the later manifestations of the disease. The former are more of an irritative and inflammatory form; the latter, including syphilitic nodes, are of a more exudative form. Virchow has shown that the indurated chancre and the node are alike in their development, the node being the highest expression of the process. All the changes of nutrition caused by the syphilitic poison, the earliest and the latest, have the same anatomical foundation; but nothing has been discovered histologically characteristic of syphilis—nothing that is not found in other constitutional diseases.

The blood and the secretions of syphilitic affec-

tions can be pronounced with absolute certainty to be the conveyers of the poison—the semen and ovum with less certainty.

Although the key to the manifestations of syphilis is in a certain poisoned state of the system, it by no means follows that the blood must necessarily at all times contain the poison. On the contrary, the whole history of the stages of syphilis points to an intermitting blood-poisoning, originating from some permanently affected centres, for instance, the lymphatic glands. Under favouring circumstances, the poison contained and temporarily enclosed in them passes anew into the general circulation; and it is thus that the occasional latency of syphilis is explained, not that its real latency is so frequent as is often supposed.

One great advance in the study of syphilis of late years has been the recognition of many syphilitic affections of organs besides those of the bones, that is, of visceral syphilis; and besides this, we have learnt to look on syphilis not merely as a specific disease, but as one having a good many points of analogy with other dyscrasies. We also are more in the habit of individualising the patient and the disease,—the former according to his constitution, the latter according to its stage of development and its complications. The treatment has thus become much more rational; and, although mercury and iodine are still our chief remedies, they are used with more discretion, and more attention is paid to the conditions of healthy blood-making, especially, nourishing food and fresh air; and on the whole there is no more satisfactory method of treating syphilis than the balneological one, in conjunction with these two chief remedies.

In making this observation, the old notion, now only entertained in some places in Spain, that sulphur-baths have a specific effect in syphilis, is disowned. All experienced bath practitioners are now agreed that sulphur-waters only afford an admirable support to other measures employed against syphilis. Nevertheless, they believe that this support is given better by sulphur than by other waters; for instance, that rupia is more easily cured by a sulphur than by a salt spring.

According to Dr. Reumont, the following are the cases that do best under sulphur-water treatment.

a. In the cases of individuals who have been already subjected for a longer or shorter period to antisyphilitic treatment, and first those on whom no palpable signs of syphilis are to be found, or who have only some suspicious symptoms, such as rheumatic pains, the bath treatment becomes a sort of test and security. Next come convalescents, who are suffering more or less from the effects of medicines, and especially from mercurial courses. In these cases, also, the bath-cure is sometimes a test, for occasionally, after the symptoms of mercurialism have been cured, syphilitic symptoms reappear.

b. In case of patients, about whom there is doubt whether their symptoms are referable to mercury, to some other dyscrasy or to syphilis, sulphur-baths afford valuable means of diagnosis.

c. In syphilitic patients, who are suffering from a combination of syphilis with mercurialisation, or from rheumatism or gout, sulphur-baths serve as preparatory treatment.

d. Patients who, suffering from any form of constitutional syphilis, use the waters along with specific medicines, also obtain benefit.

The theory of the operation of sulphur-waters in

these cases is, that they act by causing a more rapid transmutation of tissue, by stimulating all the secretions—thus acting on the blood-preparing organs, and especially on the lymphatics, occasioning a resolution of the enlarged lymphatic glands, which we have above had occasion to consider as the special depots of the syphilitic poison.

The belief in the value of sulphur-baths in such cases, is supported by vast clinical experience not only in Aix-la-Chapelle, which is the chief German bath of the kind, and in Nenndorf—but also in the admirable sulphur-baths of Hungary, in the Swiss baths, and especially in those of the Pyrenees. French and German writers both give pretty much the same account of the operation of these waters.

The sulphur-water treatment is especially valuable for diagnosis. In spite of the improved diagnosis of late years, cases occasionally occur, which leave the physician in doubt, whether the symptoms are referable to syphilis or to mercurialism. Thus many forms of pains of the bones and joints and many neuralgias, particularly if they are of an irritative nature, become worse under the use of baths, and discover their real nature by developing characteristic syphilitic affections of the surface.

Very important for further treatment is the diagnosis of affections caused by mercury, from those caused by syphilis. Manifest symptoms on the mucous membrane of the mouth, sometimes elevations and swellings of it resembling *plaques*, occasionally small ulcers, pains in the limbs and joints, great lassitude and weakness, and other disturbances of the balance of the system, are usually of mercurial nature, and disappear fast under the use of baths. Other cases are, the important combination of syphilis and hydrargyrosis. Reumont is satisfied from his own experience, that mercury sometimes does not cure the syphilis against which it is directed, although it may operate to the extent of bringing on mercurial dyscrasy. Syphilis and mercurialism may co-exist in the same person. Such cases are among the most frequent in bath-treatment; and that treatment operates in two ways—first, by alleviating the hydrargyrosis, and secondly by supporting the medicinal treatment of the syphilis. Antimercurialists make use of cases of this kind, to deny the existence of constitutional syphilis, and to prove that the syphilitic symptoms are in reality mercurial. Their doctrine is thus formulated by Lorinser, ‘All those forms of disease, which constantly take a quick departure along with the exit of mercury from the system, can only be regarded as cases of mercurial dyscrasy. This dyscrasy is not completely cured until, under the continued use of iodide of potassium, no more mercury is recognisable in the urine.’ On this Reumont remarks, that the truth of the proposition that forms of syphilis badly treated with mercury, improve rapidly under bath-treatment, is a matter of daily experience, but not so the complete cure of the disease. Whoever knows how rare it is, even with the aid of electrolysis as well as the use of iodide of potassium, to discover mercury in the urine of patients undergoing a mercurial cure, will not attach much value to Lorinser’s test. J. MACPHERSON, M.D.

(To be continued.)

SMALL-POX caused twenty-four deaths in Vienna during the week ending May 23. The number in the previous week was nineteen.

ANATOMY AND PHYSIOLOGY.

LENHOSSÉK ON THE OCCURRENCE OF CARTILAGINOUS BODIES AND TRUE BONE IN THE PENIS OF AN ADULT.—Virchow's *Archiv*, vol. lx. Heft 1, opens with a paper by Dr. J. von Lenhossék, Professor of Anatomy at Pesth, illustrated by a plate, representing the dorsal and urethral bones, with the microscopic appearances, found in the penis of a man aged forty-two, who died of typhus. Rokitsky and A. Förster (*Handbuch der Speciellen Pathologischen Anatomie*, Leipzig, 1863) both mention the occurrence of fibroid growths and tumours, which became converted into bony plates, in the fibrous septa of the corpora cavernosa penis, &c., as occasional sequelæ of injuries and inflammations. M. Velpeau (*Nouveaux Eléments de Médecine Opératoire*, Paris, 1839, tom. iv.) and Cleland, have carefully described two such cases. (See also L. Stroh-mayer's *Archiv für physik. Heilkunde*, 1844, Heft 2.) In those cases where the microscope has been used, these bony plates of the virile organ have been found to be mere calcifications, so that A. Förster holds the occurrence of true ossification in the human penis as hitherto unproven. The present case is of peculiar interest, as there were not merely bony plates, but a regular series of these, and of cartilaginous bodies; and besides this, the hitherto doubtful occurrence of the formation of true bone is established by microscopic examination.

The penis in question measured 4.1 inches from the root to the tip of the glans, with a breadth of $1\frac{1}{2}$ inch at the widest part of the shaft—a little more at the glans. On first inspection a small nodule (*Höcker*) was noticed to the right of the vena dorsalis, at a distance of 2 inches from the tip of the glans. Otherwise it appeared normal. By palpation this nodule was found of bony hardness, and on the left side of the dorsal vein a second similar hard body could be felt, about $\frac{1}{2}$ of an inch higher up. At a distance of $2\frac{1}{2}$ inches from the tip of the glans, on each side of the pars cavernosa urethræ, a body of like bony hardness was to be felt. Besides these four bone-like bodies there was considerable induration and thickening on both the dorsal and the ventral aspects. The whole of the cartilaginous and bony growths were found in the trabecular tissue of the corpora cavernosa, and extended into the glans itself. To isolate these growths was a work of some difficulty. The formation of bone comprised, (1) a dorsal bone with an angular groove for the dorsal blood-vessels, and (2) a series of three ventral bones with angular grooves for the urethra (urethral bones); the cartilaginous formations comprised a median appendage of the dorsal bone, and a strong cornet-like body with three ventral appendages (one median and two lateral). These were of whitish colour, whilst the bones were decidedly yellow. The dorsal bone had a handle or manubrium, $\frac{1}{2}$ of an inch in length, which diverged into two sharply rhomboidal bony lamellæ, each about $\frac{1}{2}$ of an inch in breadth. The whole length of the dorsal surface was about half an inch in the middle line, or a trifle more, measured to either end of the fork, whose angle of divergence was 93° . The urethral bones were rather smaller, but of similar shape, the groove formed by the divergence of the forks for the urethra having angles of 95° or thereabouts. The principal cartilaginous growth was cornet or funnel-shaped, and is somewhat quaintly termed by the author *Amiculum*

chondroideum [he borrows this name from J. J. G. Schneller, *Deutsch-lateinisches Lexicon*, Leipzig, 1789.] The extreme length of the dorsal wall of this funnel was nearly 2 inches, whilst the ventral wall was only $1\frac{1}{4}$ inch. This body was chiefly situate in the glans, and commenced close to the meatus urinarius. The other pieces of cartilage were smaller. The microscope showed a good deal of elastic tissue, with bundles of connective tissue in these growths; whilst the 'bones' consisted of an outer layer of connective tissue, with some elastic fibres; of a middle transitional or ossifying layer; and of an inner, or true bony layer, with lacunæ, canaliculi, and Haversian canals. The author remarks that these growths, and the general fibroid changes, must have much impaired the erectile capacities of this organ. A friend of his, Dr. J. Rózsay, reports that he distinctly felt 'bones' in the penis of a patient who consulted him on account of a 'defectus erectionis.'

Professor C. von Sigmund (of Vienna) writes that he has observed (in the living) indurations of a gristly, or even bony hardness, in the penes of those who have suffered severely from syphilis. The corpora cavernosa, and usually the dorsal portion, were the seat of these indurations. In these cases, coitus was painful, though ejaculation was not prevented. He has noted five such cases, in which he believed the ossification to be in the lymphatics of the penis; in every case the organ was diminished in size. This opinion, however, is not yet confirmed by post-mortem or microscopic examination. Dr. von Lenhossék remarks that the three urethral bones of his case, viewed collectively, reminded him forcibly of the os priapi of certain animals.

W. BATHURST WOODMAN, M.D.

FELTZ AND RITTER ON THE ALKALINITY OF URINE.—V. Feltz and E. Ritter (*Journal de l'Anatomie*, Feb. 1874, p. 311) have conducted a series of observations on the human subject, and made experiments on dogs, upon this subject. They arrive at the following conclusions. 1. The urine is only very rarely ammoniacal except in affections of the genito-urinary apparatus. The occurrence of alkalescence in the great majority of cases is to be ascribed to defects in the vessels, or to the mixture of the urine with more or less altered albuminous substances. 2. Urine placed in contact with the ammoniacal ferment, whose activity has been tested by its action on a solution of pure urea, does not undergo the ammoniacal fermentation with such rapidity as might appear from its composition. 3. The urine of sound healthy animals exempt from vesical or renal affections, does not become ammoniacal by prolonged retention in the bladder, produced by different mechanical methods. 4. Catheters impregnated with the ferment are not sufficient to render the urine of healthy animals ammoniacal. 5. The urine becomes ammoniacal temporarily, when a catheter, impregnated with the ferment, is allowed to remain in the bladder. 6. The same effect is produced on introducing into the bladder a solution of the ferment, and retaining it by mechanical means for about twelve hours. 7. Uræmia cannot be ascribed either to the retention of urine, or to the carbonate of ammonia produced by the decomposition of urea; for the former of these two substances is innocuous, and the second does not produce convulsions, unless in concentrated doses, the production of which in the blood is difficult to admit. 8. The decomposition of urea into carbonate of ammonia only takes place

under the influence of a ferment or chemical agents which we have not taken into account here. This decomposition does not appear to take place in the blood, for injections of urea and the ferment did not produce uræmia. 9. The chloride, sulphate, phosphate, tartarate, benzoate, and hippurate of ammonia, when injected in sufficiently concentrated solutions into the blood, produce, from a physiological point of view, effects similar to those of carbonate of ammonia. These salts are rapidly eliminated by the urine and saliva; the tartrate and benzoate do not undergo their usual transformation. The urine never becomes ammoniacal; and the breath is free from ammonia. 11. These salts, though of such a strength in solution as not to dissolve the red blood-corpuscles, nevertheless modify the properties of the latter. This fact is demonstrated by examination with the microscope, and by analysis of the gases contained in the blood; the absorptive capacity of the red blood-corpuscles for oxygen is notably diminished; while, on the contrary, the resistance to the action of water and acetic acid is increased. WM. STIRLING, D.Sc., M.B.

MEDICINE.

WISLIZENUS ON TRICHINOSIS.—An original communication by Dr. A. Wislizenus, in the *St. Louis Medical and Surgical Journal* for July, 1873, gives an account of a small outbreak of this disease, characterised by several unusual features. He says, 'The family were Germans, who generally enjoyed good health, with the exception of occasional fevers. On January 25 I was called to see three sick children, of the respective ages of eight, ten, and twelve years. They had been ailing for about five days with symptoms of gastric catarrh, *i.e.* nausea, want of appetite, coated tongue, light pain in the bowels, diarrhoea, thirst, hot and dry skin, quick and feeble pulse, and general feeling of prostration. Upon inquiry I ascertained that the family had bought a fine-looking dressed hog; that they had cut it up and salted it, and that a small portion of it had been roasted and eaten by them a week previously. They stated also that part of the meat had not been sufficiently done. Three other children and three grown men, who had eaten freely of it, remained perfectly well. I took some pieces of the pork for examination. I gave one to Dr. Engelmann, who found some unencysted trichinæ in it. In the other pieces, I found them also, but not in great numbers, none encysted, not all even coiled. The trichinosis of that hog was therefore constated (*sic*) as a recent infection, which gave a better prognosis for the sick children. Two weeks after the pork dinner, I got a fourth patient. The mother had symptoms similar to those of her children. I considered her disease also as trichinosis, but she assured me that she had not touched or tasted any of that pork. Her prostration became quite alarming, and continued for a long time. It was highly interesting to me to ascertain, several weeks after she was laid up, that she had assisted in the cutting up of the hog, and that she had taken from a saw used on that occasion some small pieces of raw lean meat, tasted them herself, and given small bits to the same three children who were first taken sick. She could not be induced to believe that a few mere fibres of meat could produce so terrible a disease. I entertained no doubt that the

riddle of the true origin of the disease had been solved by this trifling circumstance. That the smallest piece of raw trichinous meat is far more dangerous than affected meat given in any other form, is self-evident. Three weeks afterwards the family hospital was increased by a fifth patient—a young man in their employ. He had several times partaken of the roasted pork, but remained well for nearly three weeks, when he was suddenly attacked. I considered his case also a trichinous affection in a milder form. In about a week he got up again; his œdema had disappeared, his appetite returned, and in a week more he seemed to be quite restored. My first patients, the three children, continued their slow course towards recovery. The youngest child, however, who from the first was more severely attacked, experienced a relapse, and died from exhaustion on April 6, eleven weeks after the commencement of her disease. When I arrived the funeral was already so arranged that I obtained only a chance, with the permission of the father, to cut a small piece out of the gastrocnemius muscle for microscopic examination. Never before had I seen a muscle so saturated with trichinæ. In a small piece of the size of a pin's head, I counted about a hundred. Some seemed to be entirely free, others showed the commencement of encysting, none were really encysted. Dr. Engelmann found some alive, and on putting them in a few drops of water, at blood-heat, they exhibited very active motions.' T. S. COBBOLD, M.D.

FAUVRE ON PULSATION OF THE SUBCLAVIAN AS A SIGN OF SUPERIOR DILATATION OF THE AORTA.—Dr. A. Fauvre writes (*Archives Générales*) that, contrary to what is observed under normal conditions, there may be noticed in certain cardiac affections peculiar pulsations in the carotid region, and at the base of the neck. That these pulsations originate in the passage of the blood-current through a large artery—the subclavian—may be shown in two ways: first, by placing the finger back of and below the tubercle of the scalenus anticus muscle, when this artery will not be found in its usual position; then by making compression over the seat of pulsation, when the pulse at the wrist is affected. If, on making this compression over the misplaced subclavian, the arterial walls be lightly impressed by the finger, a double vibratory tremor may be remarked. The first and most intense part of this is systolic, and is evidently produced by the rapid centrifugal passage of the blood-current. The second, of variable intensity, is caused by the return of the blood towards the heart; it is sometimes wanting.

Auscultation over the seat of pulsation demonstrates the existence of a double blowing murmur, evidently connected with the vibratory tremor above mentioned. The second part of this murmur is wanting when the second part of the tremor is absent.

In a number of necropsies of such cases, the existence of aneurism affecting the superior wall of the aorta has been ascertained. In these cases the subclavian, is found displaced, and overlapping to a certain degree the omo-hyoid muscle. It is at first uncovered behind the clavicle, and then becomes more superficial. Finally, it is sinuous—that is, too long for its channel.

The double tremor and murmur appear to be independent of any abnormal condition of the aortic orifice. The fact appears to be that the walls of the dilatation, true or aneurismal, having lost their

elasticity, allow themselves to become distended under the influence of the ventricular wave at the same time as the arterial system. But, owing to the impulsive force of the heart having been exhausted by the inertia of these walls, the arterial tension is lessened.

The diastolic reflux of a part of the contained blood results of necessity from this unequal subdivision of the blood-tension. It is the centripetal reflux which determines the diastolic murmur. The displacement of the subclavian is evidently due to elevation of the superior wall of the aorta. It is shown in the shortening of the course of the carotid and other vessels given off, causing them to become sinuous, and thus to give rise to the pulsations noted. If the aortic dilatation be equal over all parts whence the great vessels are given off, the various phenomena alluded to will be observed equally on both sides of the neck. If, on the contrary, it be greater near the aortic origin, or on the other extreme of the arch, pulsation, &c., will only be observed on the affected side.

We have here, then, a valuable aid in the diagnosis and prognosis of superior aortic aneurism. For not only may the extent and position of the enlargement be ascertained approximately, but, if in the progress of the case the vibration and murmur should disappear, we may hope that the aneurismal pouch is being filled with clots.

BOILEAU ON THE SPHYGMOGRAPH.—In a thesis for the degree of M.D. at Dublin, Staff-Surgeon Boileau discusses the value of the sphygmograph as a means of clinical research, and gives some interesting examples of its application in various morbid conditions. He points out, as the chief value of the instrument, that it not only affords a representation of the pulse with a truthfulness unattainable by any other known means, but gives a permanent record which may be carried all over the world for comparison and for instruction at any time.

Dr. Boileau refrains from any recondite disquisition as to the mechanical theory of the pulse, but he gives an explanation of the several elements of the trace, in which, in the main, he follows the views of Dr. Burdon Sanderson. As to the causation of the diastolic wave, he says that, on account of the retardation it experiences when it arrives at the mesh of capillaries, 'the blood is delayed in its passage through the artery, and this delay is represented in the trace by a corresponding elevation or curve in the down stroke; the blood-volume swells as it were by reason of the obstruction *à fronte*, and thus is formed what is called the diastolic wave.' Thus, on the question of the relation of dicrotism to arterial pressure, the author differs from the opinion in which the chief authorities on the sphygmograph are now agreed; namely, that increased dicrotism implies increased freedom of outflow from the arteries, and consequent diminution of arterial pressure.

Dr. Boileau rejects the modern improvements in the sphygmograph whereby more accurate and convenient means are afforded of varying and registering the pressure than in the original instrument of Marey. 'I have not yet seen any results follow the employment of varying pressures to convince me that it is absolutely necessary for clinical purposes

to estimate more accurately than can be done by the finger, the compressibility of the pulse.'

[We think that the author's opinion of the value of the sphygmograph will be still further raised if he obtain an improved instrument. Our own experience agrees with that of others that, in some cases, a pulse which to the finger appears small and weak, is shown by the sphygmograph to have unusual powers of resisting pressure. Moreover, even when the finger judges rightly, it fails to leave that exact and permanent record without which the mere shape of the pulse-curve can convey only imperfect information.—*Rep.*]

Among the tracings given as examples, several are from cases of alcoholism, two of which show rapid pulses with increase of dicrotism, but no tremor, while, in a third, tremor is manifested. Of the rest, the most notable are a tracing from a soldier, aged only twenty-one, convalescent from secondary syphilis, in which signs of arterial degeneration are apparent, and one taken in the sweating-stage of ague, when the pulse was 135 and temperature 103.4°, showing a rounded primary summit, and a dicrotic wave scarcely discernible. A. L. GALABIN, M.D.

MATERIA MEDICA AND THERAPEUTICS.

CHAUVEL AND VERNEUIL ON THE ADMINISTRATION OF CHLORAL IN TETANUS.—At a recent meeting of the Paris Société de Chirurgie, reported in the *Progrès Médical* of May 2, M. Chauvel read notes of two cases of traumatic tetanus treated by chloral, in doses averaging 37 grammes (about 1½ ounce) during the twenty-four hours. The chloral did not produce any relief of the symptoms, and both patients died.

M. Verneuil also read notes of two cases in which chloral given in doses averaging about a drachm and a half in the twenty-four hours in one case, and two and a half drachms in the other, cured both the patients.

Chloral has been administered in various ways in tetanus; and the objections to its administration by the mouth may be enumerated as follows. Some patients cannot swallow the medicine; in other cases a passing relaxation or none at all is the only result obtained by the administration of 15 grammes of chloral; and finally the patients may show serious symptoms which would make it dangerous to wait three, four, or five hours for the effects of the drug. If the chloral do not act, either the drug is of bad quality, or absorption does not take place, and then another channel must be chosen.

Injections have been tried, but this plan is as little to be relied on as the administration by the mouth; besides which it is necessary to move the invalid, which is always a serious inconvenience. In a painful surgical affection in which M. Verneuil could not give chloral either by the mouth or by the rectum, he made subcutaneous injections. These gave great relief; but in tetanus it would be necessary to employ large doses and to make numerous incisions, which would bring on local inflammation. Hence intravenous injections suggested themselves, and the first researches in regard to them were made by M. Oré, of Bordeaux. He has nevertheless been wrong in wishing to substitute intravenous injections

in all cases and at all times for other modes of administration.

The quantity of chloral necessary to put a patient to sleep was already known, and that quantity could easily be injected into the veins; but M. Verneuil did not inject from 150 to 180 grains into the veins of a tetanic patient without feeling much uneasiness. It is known that fifteen or thirty grains sometimes siterate or act very suddenly on certain patients. With regard to the facility of the operation, MM. Cruveilhier and Labbé have declared that it is not so easy as M. Oré has asserted; if the subject be fat or young, it will be difficult. If the malady be not arrested at the outset, it may be assumed that chloral will have to be given for twenty or thirty days, and it then becomes a question whether the vein shall be left exposed during all this time or a fresh puncture be made every time.

M. Verneuil does not absolutely reject M. Oré's method, but he would not believe himself authorised to begin the treatment of a tetanic patient by intravenous injections. Up to the present time, M. Verneuil has cured five cases of tetanus by the administration of chloral hydrate by the mouth, making a proportion of two-fifths of cures.

GAZEAU ON THE USE OF SULPHATE OF CADMIUM IN ACUTE URETHRAL BLENNORRHOAGIA.—After having ascertained that one of the best treatments for acute arthritis is the employment of injections of sulphate of zinc, frequently repeated in the proportion of one-third to one five-hundredth part, or most generally a fifteen-hundredth part, Dr. Gazeau has tried to substitute for it the sulphate of cadmium, which has a much more powerful action than the sulphate of zinc, its astringent action being more energetic and persistent. Dr. Gazeau employs in urethritis injections of sulphate of cadmium, varying from the thousandth to the eighteen-hundredth part. These injections, administered every two hours very rapidly, quiet the acute stage of blennorrhagia, which passes to the latent state. The treatment lasts from fifteen to twenty days.

During the first two days copaiba may be used in conjunction with this treatment.

In chronic blennorrhagia of some years' date, sulphate of cadmium is powerless. In certain cases, however, cures may be obtained by associating it with subnitrate of bismuth, according to the following formula:—

| | | |
|-----------------------|-----------|-------------|
| R. Distilled water | | 100·00 grs. |
| Sulphate of cadmium | | 0·07 |
| Subnitrate of bismuth | | 7·00 |

An injection of this should be used every time after urinating.

RAGLAND ON BROMIDE OF POTASSIUM FOR CONVULSIONS OF CHILDREN.—Dr. Ragland, of Sheltonville, Texas (*New Orleans Medical and Surgical Journal*, May, 1874), remarks that the presence of a small bolus of indigestible food, or of worms in the alimentary canal, are such frequent causes of convulsion among children that the popular mind holds the belief that worms are the cause in all instances, and will frequently desire the physician to prescribe an anthelmintic. In all cases of infantile convulsions resulting from nervous irritation, whether centric or excentric, he would give bromide of potassium with perfect confidence of controlling the convulsions, while at the same time endeavouring to

remove by appropriate means the cause, should he be able to discover it.

The following is his usual formula.

| | | |
|---------------------|-----------|-----|
| R. Potassii bromidi | | 3j |
| Tincturæ gelsemini | | 3j |
| Tincturæ Valeriani | | ij |
| Syrupi simplicis | | 3ij |
| Mix. | | |

To children under one year of age, one teaspoonful is given every hour till relief is given. This is usually obtained in a short time, after which the effect is continued by using the remedy less frequently, say at intervals of two or three hours. This he has used especially in the convulsions frequently complicating the fevers of children. In no case has it failed to afford the desired relief.

BLIGH ON BROMIDE OF POTASSIUM IN GONORRHOEA.—Dr. John W. Bligh, in the *Practitioner*, recommends that, as soon as a patient complains of gonorrhœa, bromide of potassium should be immediately commenced, and continued throughout the duration of the disease. As it is said to increase the acidity of the urine, an alkaline bicarbonate should be combined with it. The following formula has been found useful.

| | | |
|-------------------------|-----------|------------|
| R. Potassæ bicarbonatis | | gr. lx |
| Potassii bromidi | | gr. xc-cxx |
| Tincturæ hyoseyami | | fl3ss |
| Aquæ camphoræ | | fl3vss |
| Mix. | | |

One-sixth part of this mixture is to be taken three times a day, and once during the night, should the patient happen to be awake. Care should be taken not to administer a dose during digestion, as it may, by neutralising the gastric juice, interfere with the conversion of food into chyme.

If the disease be in the first stage, an injection of the salt is recommended to be used as frequently as opportunities allow. The following is the usual form and strength.

| | | |
|---------------------|-----------|---------|
| R. Potassii bromidi | | gr. cxx |
| Glycerini | | fl3ss |
| Aquæ destillatæ | | fl3vss |

Mix. One syringeful is to be used every four hours.

When the discharge has assumed the form of gleet, a similar injection, associated or not, as may be thought advisable, with some astringent, will be useful. Dr. Bligh also administers during this latter stage from fifteen to twenty grain doses, three times a day, combined with fifteen minims of the tincture of the perchloride of iron, and dissolved in some suitable menstruum.

There are certain accessories which should not be neglected. The bowels should be carefully regulated, the proper diet prescribed, and a total abstinence from beer and other stimulants insisted on. Rest should be enjoined, and over-exertion strictly avoided. The testicles should be supported by a suspensory bandage, and the genitals bathed from time to time, especially before retiring to rest. The flow of urine may be increased by the free use of diluents.

MATTISON ON DEEP INJECTION OF CHLOROFORM IN TIC DOULOUREUX.—Dr. J. B. Mattison, of Chester, New Jersey, reports to the Meigs and Mason Academy of Medicine, February 19, a case of tic douloureux in which various agents had been used with very trifling benefit. The man had in former years been troubled with a trigeminal neu-

ralgia, and afterwards with sciatica, which had continued for many years, during which time he had acquired the habit of using morphia hypodermically and in large quantities. This, however, afforded no relief from the facial pain. On December 22, 1873, one-third of a drachm of chloroform was injected near the infraorbital foramen by passing the needle beneath the upper lip, and carrying the point to near the emergence of the nerve, where the chloroform was discharged. A severe paroxysm followed, but much lighter and far less frequent. After the 27th, no recurrence of the paroxysm took place. During this time he was placed on good general tonics, and also received three times a day hypodermically 1-48th of a grain of sulphate of strychnia, and 1-60th of a grain of sulphate of atropia, which was continued for some time. No morphia was used after the 22nd. In three weeks all desire for the latter agent had been dissipated. Six weeks later, the man had entirely recovered his health.

PELTIER ON TRIMETHYLAMINE IN ACUTE ARTICULAR RHEUMATISM.—In an article in the *Progrès Médical* (1873-74) Dr. Peltier, of Sedan, analyses the documents which have been published up to the present time on trimethylamine, and shows that this drug fulfils the three following conditions, which are those of acute articular rheumatism. 1. It diminishes and suppresses the fever. 2. It diminishes and suppresses the articular congestion. 3. It diminishes and suppresses pain. Of forty-eight cases treated by trimethylamine, twenty-two were cured in less than eight days; eleven in from eight to fifteen days; and one from fifteen to thirty days; and eight were either very little or not at all influenced by the medicine. According to M. Peltier, no other medicine can lay claim to such results; and the cures will become more and more frequent when, instead of using trimethylamine, chlorhydrate of trimethylamine, of which it is easier to determine the dose to be given, shall be employed. The conclusions of the paper are as follows. 1. From a chemical point of view, it is preferable to use the chlorhydrate of trimethylamine as a therapeutic agent. 2. Physiologically, trimethylamine slightly stimulates the action of the skin, astringes the mucous membrane, acts as a sedative on the nerves, and a hyposthenic on the arterial system; it also seems to diminish the amount of urea in the urine. 3. With regard to its therapeutic action, trimethylamine has scarcely been employed in anything but acute articular rheumatism, in which it soothes the pain, removes the congestion of the articulations, and diminishes the fever. Taking everything into consideration, it seems to be the medicine which up to the present time has yielded the best results.

SMITH ON THE TREATMENT OF DIPHTHERIA.—Dr. J. Lewis Smith, at a recent meeting of the New York Pathological Society, after presenting a pathological specimen from a case of diphtheria, gave the following synopsis of his treatment.

This patient was treated with quinine, iron, and alcoholic stimulants internally. The quinine was administered in moderate doses; but in severe diphtheria and scarlet fever large or frequent doses of this agent are tolerated, and are sometimes apparently useful. When I entered on duty in the Asylum in the same epidemic, one of my colleagues was treating a patient of three and a half years, having severe scarlet fever and diphtheria, with two grains of quinine administered hourly; and though forty-

eight grains had been given in twenty-four hours, the pulse was 156 per minute, and the temperature $103\frac{3}{4}^{\circ}$, showing that there was not such reduction of pulse and temperature as ordinarily attends the employment of large doses of this agent. The patient recovered, the quantity of quinine administered daily being, however, reduced to twelve grains.

The local treatment in the case which I have related consisted in the application to the fauces, every three hours, of the following, which has given me better satisfaction than any other medicine for local treatment which I have employed:

R. Acidi carbonici gtt. v
Liquoris ferri subsulphatis ʒij
Glycerinae ʒj

The brush was employed in preference to the probang, as it is less painful, and, where there is a false membrane, does not produce hæmorrhage by its detachment.

The small room in which the child was treated was also filled, as far as possible, with steam. As steam or water softens the epidermis, so I believe it softens and aids in the removal of the false membrane, which is mainly epithelial, more effectually than any other local measure. In each of the shallow pans from which the steam was generated, a small lump of quicklime was placed, so that the steam was charged with particles of lime, which were quite perceptible in the breath. If much lime be added, the water becomes too thick or syrupy, so as to diminish evaporation, and therefore render the quantity of steam insufficient. The spray of lime-water, whatever may be its solvent effect, certainly renders the respiration in a close and hot room more tolerable, perhaps from its rapid absorption of carbonic acid.

FORMULARY.

VILLATE'S MIXTURE.—The original formula of this solution, as first composed by Villate, is as follows:

R. Liquoris plumbi subacetatis ʒj
Zinci sulphatis crystall.
Cupri sulphatis crystall. aa. ʒss
Aceti vini albi fl. ʒvjss

Dissolve the salts in the vinegar and add the subacetate of lead. Shake before using.

Dorvault, Bouchardat, and some other authors put ʒviii of vinegar instead of ʒvjss; but Dr. Notta does not think that this modification is of any advantage, and prefers Villate's original formula.

It is important that this preparation should be made as stated. Druggists very often substitute for the white wine vinegar a solution of pyroligneous acid, in which case the liquid acts like a powerful caustic, and the patient cannot bear its application. These two solutions can be very easily distinguished at first sight: when the pyroligneous acid is used, the solution, once settled, has a bluish hue; but when prepared with the white wine vinegar it has a greenish hue. This is a capital point, for surgeons have noticed a great difference in using both preparations on the same patient. The pyroligneous acid solution has produced excessive pains and serious symptoms of irritation and inflammation.

[This very complex and unscientific fluid is warmly alleged by Notta, and by a great number of surgeons, to be of capital service as a topical application to cancrus surfaces or cavities of bones, chronic fistulæ,

and the like. Dr. Railton, and recent American reports, speak very favourably of its use in diarrhœa. It should be diluted, in the first instance, with two or three times its bulk of water.—*Rep.*]

PUBLIC HEALTH.

ON THE USE OF ZINCED OR GALVANISED IRON FOR THE STORAGE AND CONVEYANCE OF DRINKING-WATER. BY W. E. BOARDMAN, M.D., OF BOSTON.*

(Continued from page 345.)

With reference to the second part of our first inquiry—namely, what are the actual products of this action of water upon the zinc?—the conclusions at which we shall be able to arrive will not be so definite. We know that various circumstances, conditions and processes combine to render water, in its ordinary state, a very complex fluid. Receiving its constituents from the air and ground, in various combinations, the laws of which are imperfectly understood, it contains mineral, vegetable and animal matter in suspension, and gaseous, organic and mineral matter in solution. The mode of combination of these various substances in solution cannot be determined, at least with the means at our command, at the present day. It is a popular custom, however, for chemists to ascertain, by analysis, the amount of each constituent, and then to calculate the probable chemical combinations which have taken place. Carrying out this latter idea, chemists have reported that they have detected the presence of various soluble salts of zinc in water which has been in contact with this metal; the sulphate and the chloride have been reported, principally, and, in some cases, the statement has been made that water has been found 'strongly impregnated' with these salts. The real basis of these conclusions is founded upon isolated chemical experiments, made in the laboratory, like the following:†

'Zinc is rapidly dissolved in a very dilute solution of common salt [chloride of sodium] in water, and may be found in the solution, or water, as the muriate [chloride] of zinc. This would be the action of the common salt in rain-water, and it is the source of the corrosion of zinc roofs.'

'Galvanised iron, introduced into a solution of copperas [protosulphate of iron] in water, very dilute, acts thus. I soon found iron-rust rapidly falling on the galvanised pipe. In a short time all the iron was precipitated from the water, and fell in a coat of rust, while its place in the water was supplied by zinc. In other words, copperas, or green vitriol, was exchanged for white vitriol.'

'Galvanised iron, in a mingled solution of salt and of copperas, such as is found in several wells in Lowell, is rapidly destroyed; the water becomes charged with salts of zinc.'

Without entering upon the palpable sources of error in the above experiments, judging them from the published account which is given here, it may be stated that the direct inference implied—that similar re-actions always take place between zined iron

pipes and water passing through them, and containing the above-mentioned constituents—is unwarranted.

At the request of the writer, Professor Wm. Ripley Nichols presents the following communication with reference to the action of water upon zined pipes, and the products of this action.

* Massachusetts Institute of Technology, Chemical Laboratory, Boston, December 24, 1873.

'My dear Sir,—With regard to the action of water on zinc, it is well known that, when zinc is exposed to moist air, it quickly becomes covered with a film of oxide, which soon changes, under the influence of the carbonic acid of the air, into a basic carbonate. The oxide at first formed has been regarded as a *suboxide* (Zn_2O), but is now generally held to be the ordinary oxide of zinc (ZnO). That this coating subsequently changes to a basic carbonate, and that the white compound of zinc, which is often found in suspension in water which has been in contact with "galvanised" iron pipes, is a (hydrated) basic carbonate, seems to be sufficiently well established. That the compound is not perfectly definite in its composition, but contains sometimes more, sometimes less, carbonic acid, in proportion to the oxide of zinc, is also an accepted fact.

'What, however, is the state in which the zinc exists *dissolved* in water, we do not know, and probably cannot know. Although it has been stated in some cases that a given water contained in solution so much *chloride of zinc*, or so much *sulphate*, such statements rest upon purely gratuitous assumptions.

'We have good reason to believe that absolutely pure water would have no action on absolutely pure zinc; but ordinary water contains a quantity, more or less considerable, of different salts, such as chlorides, sulphates, carbonates, and in what form the small amount of zinc in solution exists, it would be impossible to say.

'We know that zinc is attacked by a solution of chloride of sodium (common salt), and that a portion goes into solution, hydrogen being at the same time evolved. In the case of a strong solution of chloride of sodium, the amount of zinc that is taken up is so considerable, that it is not unnatural to suppose that a portion of the zinc exists as the double chloride of zinc and sodium; but as undissolved oxide of zinc is also a product of the re-action, and as the solution is found to be alkaline, it is probable that, at the same time, some compound of oxide of zinc and oxide of sodium (zincate of sodium?) is also formed.

'In the case of a drinking-water, which is a dilute solution of a variety of salts, the case would be very different, and although we know of this action of chlorides on zinc, we also know that nitrates and sulphates and other salts likewise attack the metal and are capable also of dissolving its oxide; we know further, that the oxide and all the carbonates of zinc dissolve in water containing carbonic acid, so that we are unable to say whether the trace of zinc found in solution existed as chloride, nitrate, or sulphate, or as a salt of some organic acid, as (acid?) carbonate (or carbonate held in solution by carbonic acid), or whether a portion existed in each and all these different states.

'I may, perhaps, make my meaning more clear by using an illustration. If we mix together very dilute solutions of chloride of calcium and of sulphate of magnesium, we obtain a mixture which is not distinguishable in appearance from the solutions from which it was produced. If we submit it to chemical

* From the *Fifth Annual Report of the Massachusetts Board of Health*. 1874.

† Extract from a report to the City Council of Lowell, Mass. 1842. From Appendix to 'Lead-Diseases,' by L. Tanquerel des Planches, Lowell. 1848.

examination, we find that it contains a sulphate (or sulphates) and a chloride (or chlorides); also, that it contains magnesium and calcium. Analysis does not, and cannot, show whether the solution contains chloride of calcium and sulphate of magnesium, or chloride of magnesium and sulphate of calcium, or whether it contains some chloride and some sulphate of calcium and some chloride and some sulphate of magnesium. The latter view, in fact, has the greater probability; the proportions in which the distribution occurs taking place according to some law at present not understood. But according to the fashion, formerly universal, which even now prevails to a certain extent, the solution, if analysed, would be said to contain so much sulphate of calcium and so much chloride of magnesium, and for this reason: If the solution be concentrated by evaporation, sulphate of calcium will crystallise out, and may be obtained nearly free from chloride of magnesium. This, however, does not prove the previous existence of all the calcium as sulphate, for the condition of things in the liquid is changed by concentration. It is a general law, that when solutions of two chemical substances are mixed, if such a re-arrangement of the acid and basic radicals be possible, as to form a compound, *insoluble* in the liquid employed, or a *gaseous* compound, such compound will be formed; but where no insoluble or gaseous compound is formed, we cannot judge of the change which takes place.

‘Therefore, I do not hesitate to say, that we do not, and cannot, know what compound of zinc is present in solution in the case of water which has passed through “galvanised” iron pipes.

‘Yours respectfully,

WM. RIPLEY NICHOLS.’

‘DR. W. E. BOARDMANN.’

Vauquelin and Deyeux,* Devaux and Dejaer,† Mallet,* Schaufële,* Gautier de Claubry,‡ Tardieu,\$ Pettenkofer,* Brande and Taylor,|| Bouchardat and Fonssagrives,¶ W. R. Nichols,** all state—indeed, it is a well-known fact—that zinc, when exposed to the action of common, potable water, acquires a coating of oxide, which is practically insoluble in water. This coating, subsequently, is acted upon by the carbonic acid, which comes into contact with it, and it results from this, that the layer is finally composed of oxide, carbonate, and a combination of these two, regarded as oxyhydrocarbonate of zinc by Pettenkofer.* By mechanical and galvanic action and solution, the removal of this layer is effected gradually, and the water then contains more or less of these compounds in suspension, while the remainder enters into solution.

This much, then, is all that can be stated positively, at present, with regard to the nature of the products in question.

In regard to the amount of zinc, in all forms, metallic or other, which may be present in the water, many influences come into consideration. The water may contain ingredients, abnormal in kind or quantity, which will act with unusual energy upon the

zinc, or it may be of such purity as to have but a slight action upon the metal. Again, as shown by Mallet,* imperfect construction of the material—if the iron be not properly freed from the initial rust or if the zinc be incompletely applied, will favour the corrosion of the zinc, for, as soon as the iron is exposed, the destruction of the zinc goes on more rapidly. The texture of the zinc, too, whether fine or coarse, affects the results.† If impure zinc be employed, it will be more readily destroyed. The length of time during which pipes have been in use, also, is to be taken into consideration.

The action of potable waters of the purity of the Cochituate is comparatively feeble. We have seen that this water, drawn through pipes which have been in use for eight or nine years, contained only 00·62 grain of metallic zinc to the gallon, while some chemists have reported the presence of from two to six grains ‡ in the gallon of other waters, and this latter fact is freely admitted by the manufacturers. It is to be observed, however, that in these instances of the presence of such a large amount of zinc, it is always in the form of the carbonate, principally, and the water presents a turbid appearance, which would deter most persons from using it for drinking or in cooking. In the experiments of Schaufële,‡ water allowed to stand in galvanised iron vessels for five days contained only traces of the oxide of zinc.

(To be continued.)

OBSTETRICS AND GYNÆCOLOGY.

LEVY ON ENDOMETRITIS CERVICALIS GRANULOSA.—Dr. Levy (*Ärztliches Intelligenzblatt*, February 4, 1874), states that granular ulceration of the os tincæ is a very frequent consequence of cervical endometritis. If the cervix be dilated by laminaria or sponge-tents, the same condition—elevated granular intensely reddened surface—as seen on the os tincæ is visible some distance up the canal, covered with a semi-transparent purulent layer of mucus. The position of the uterus is rarely normal, or only approximately so; in the majority of cases it is bent forwards; it is rarely retroverted, and when it is, the retroversion is so acute that the os is either behind or above the symphysis pubis. In either form of malposition, friction of the affected part against the vaginal walls exists. If the surface be wiped dry with cotton-wool, and watched, after a short time a brown or reddish brown film is formed, whilst from within the os there continually flows out over the swollen lips a glairy or purulent mucus. The raw granular surface, which was previously glazed, becomes gradually changed through this mucus trickling over it, from a transparent white to a dull grey. As often as this layer is removed, the same condition will reappear. If the cervix have been dilated, the same thing is observable within the canal. Healing begins at the junction of the vaginal mucous membrane with the hypertrophied os; by degrees it extends over the os tincæ and upwards into the canal. The mucous discharge becomes more glairy and transparent as the process continues, until finally only a cork-like

plug of mucus is seen closing the canal. This plug of mucus the author has often observed to move synchronously with the act of respiration. No irritation of the os or cervix will cause its expulsion, which would be the case if the theory of Holst and Vierordt were correct, that the lips of the os were capable of expansion and contraction under certain stimulus, viz., coitus. The string of tenacious mucus found exuding from the cervical canal, was shown by Dr. Kristeller to be of the greatest importance in preserving the spermatozoa, but he at the same time believed it to be secreted partly by the internal surface of the uterus. Dr. Levy, by repeated experiments, has proved that it is secreted entirely by the follicular glands of the cervix.

Granular ulceration of the os depends, in the author's belief, in the majority of cases, on some flexure of the cervix, or on some swelling of the mucous or submucous membrane of the canal, and closing it. It is frequently accompanied with hypertrophy of the anterior lip of the cervix. This flexion and swollen condition of the cervical mucous membrane retards the natural flow of the menstrual blood, which becomes retained in the folds of the arbor vitæ, giving rise to irritation and subsequent abrasion and ulceration of its surface. During the first weeks of pregnancy it is not unusual to find abrasion of the os, which arises from a retardation of the backward flow of blood, and from the low position of the uterus causing constant friction of the os against the walls of the vagina. It entirely disappears as gestation advances.

Dr. Levy proposes to dilate the cervical canal by means of sponge or laminaria tents in all cases of granular ulceration of the os, in order to remove the primary cause of the affection. He states that he has employed them for some considerable time, and that this treatment has almost invariably been followed with the most happy results. At the same time he pays the greatest attention to the constitutional condition, and seeks to remove all causes of local congestion, loaded bowels, &c., as also to prevent friction of the raw surface against the vaginal walls by means of pessaries or cotton-wool plugs dipped in glycerine alone, or glycerine and some astringent. Ergotine dissolved in glycerine he recommends as an excellent remedy.

FASBENDER ON INTERCURRENT DYSMENORRHEA.—At a meeting of the Gynæcological Society of Berlin on February 3 (*Berliner Klinische Wochenschrift*, April 20) Herr Fasbender described a case of intercurrent dysmenorrhœa.

The person was a single lady, aged twenty-four, anæmic, with the periods quite regular. The 'flow' was always scanty, and was preceded for some days by intense pain at the hypogastrium and gastric disturbance. The last few years it was accompanied with a slight fluor albus. For two years the same troubles, together with leucorrhœal discharge, had occurred fourteen or sixteen days after each menstrual period. Vaginal examination showed acute ante flexion, endometritis, chronic colpitis, and erosion of the os; in the region of the ovaries, especially around the uterus, nothing abnormal could be found. A subsequent examination, fifteen days after the last period, along with a feeling of weight in the pelvis, proved that there existed an increase of the fluor albus.

From the above case the author endeavoured to show how inapplicable the ruling theory was, as

to the etiology of intercurrent dysmenorrhœa—the expression of a kind of incarceration of a follicle from some inflammatory process of the ovaries. He did not attach the chief importance to the pain, but to the congestive phenomena, and believed that further investigations would show that these complex symptoms, according to the menstrual theory of Pflüger, were connected with an increased reflex irritability. In the discussion that ensued it was the general opinion that the flexion could not be considered as the principal cause, otherwise this form of dysmenorrhœa would be of more frequent occurrence, but that it was a complex action depending on certain conditions of the nervous system, coupled with some derangement of the ovaries. Most speakers who had met with instances stated they had observed a bloody discharge occur at the same time.

W. C. GRIGG, M.D.

PSYCHOLOGY.

KOSTER ON UNRECOGNISED INSANITY.—Dr. Koster has for some time been engaged in describing a number of persons in whom the insanity was not recognised, albeit they were known to be lazy, incorrigible, always getting into trouble, &c. Some selections from Dr. Koster's 'gallery' have been already given in the LONDON MEDICAL RECORD, and we now give the chief points of the summary that he makes (*Irrenfreund*, no. 12). Hereditary taint, although the history was very difficult to obtain in many instances, was nevertheless marked, amounting in round numbers to 60 per cent. The development of the malady is threefold. It comes on either gradually from early youth, as a constantly increasing manifestation of mental defects, such as roguery or vagabondism; or else appears at puberty, or perhaps later still in life, after some such cause as injury to the head, blighted affections, excesses, fevers, &c. The course of the insanity is either by a slow increase of the symptoms, or by excitement, fury and destructive tendency. Hallucinations of the higher senses are rare, and still more so are fixed delusions. In one girl and in three men a state of dementia rapidly supervened with motor paralysis; whilst in two there were optimist feelings, and in the other two a state of melancholy. The form of the disease is not pure, but rather mixed. Based on a state of melancholy or moroseness there are frequently large and supercilious notions superadded. The melancholy takes an active form in the way of suspicion against the family surroundings and the world in general, disposition to show anger, and constant bemoanings and complaints. Sometimes the patients take to listless wandering about, at other times they fall rapidly into dementia. The individual symptoms vary according to the peculiar temperament of the person; some may be altogether absent, but there is in most, if not in all, instances an abnormal state of irritability, to which may be added lesions of common sensibility of the most various kinds, insane feelings amounting to fury of the highest degree. This irritability much resembles that seen amongst epileptics, who form the *enfants terribles* of asylums. It is especially among women that complaints are made, and then they assume the hysterical form, pointing especially to the præcordial region, the head, the uterus, or a general

feeling of weight and pain in the limbs. At times, however, the men complain also, and one is inclined to attribute to them either simulation or exaggeration. Most of the persons of this class are inclined to intrigue, lie and quarrel, and to shirk work. This shirking of work shows itself in different ways. Some will occupy themselves for a time in a light occupation; others only under constant supervision and stimulation, and even then they adduce the most trifling excuses to be spared the labour; whilst many are absolutely incapable of work in any form. One very striking phenomenon is an irremediable chattering, a sort of brain-diarrhoea, and they may be listened to for hours at a time without any definite conception of what they are talking about. Others, on the contrary, refuse to answer the questions put to them, or will only converse with certain individuals. Absolute and concrete delusions are seldom met with, though there may be an exaggerated self-feeling, and they talk of being 'occupied with their own affairs,' without time to attend to work placed before them. Periodical exacerbations are witnessed, chiefly shown in emotional excitement, and at times they amount to positive fury. It is now that attempts to escape oftenest occur, whereas, as a rule, in spite of their complaints and discomfort, they are well contented with the asylum. The bodily condition is mostly good, and many have an attractive appearance and intelligent expression. Notable bodily defects are wanting, though on close examination it is apparent that one may have a peculiar skull-formation, in another the face is non-symmetrical, and a third may show a decided scrofulous habit. Impulse to drink amongst the men, and sexual propensity in the women, have been said by some to be constantly met with, but this is not accordant with Dr. Koster's experience. An exact and scientific inquiry into the houses of ill-fame in large cities might discover that many of the denizens are persons of a low degree of intellectual power. It remains a fact that all these people have been hitherto wrongly estimated, and on the ground of public morality have been placed in inappropriate institutions; whence, on the supervision of an attack of melancholy or fury, they have been removed to an asylum as incurable or only capable, under constant supervision, of improvement. Good food, tepid baths, and injections of morphia, with rest in bed are the principal therapeutic measures. We may recognise here a group of cases which, from their development, cause, and symptoms, vagabond life, hereditary influence, irritability, and perversity, with periodic exacerbations and remissions, may be classed as 'deluded rogues and parasites of society.'

T. C. SHAW, M.D.

NEW INVENTIONS.

HAMPSON'S SUGAR-COATED PILLS.

The advantages of sugar-coating pills are beginning to be fully recognised in this country. We have received from Mr. Hampson, 205 St. John Street Road, London, E.C., specimens of useful formulæ; of which his list includes in all 157 varieties. He alleges, and we concur with the statement, that a coating of pure white sugar is the least objectionable covering that can be put upon pills, and besides being in itself unobjectionable, it has many advantages over

the earthy and resinous coatings adopted by some manufacturers. 1. Sugar being readily soluble, the pills begin to exercise medicinal action almost as soon as they are admitted into the stomach. 2. The sugar-coating has an important preservative effect on the pills coated. 3. The pills are less accessible to dampness and change, than other coated pills, and they keep their properties unimpaired for a very considerable time, and in any climate.

The pills manufactured in Mr. Hampson's laboratory are warranted to be made of genuine drugs of official potency. They are compounded with the utmost accuracy and care, and, being coated at a very low temperature, are uninjured in the process.

MISCELLANY.

PROFESSOR KUSSMAUL, of Freiburg, has been invited to succeed Professor Lebert, at Breslau, who is about to retire; but he has declined the invitation.

CHOLERA attacked 765 persons in Upper Silesia during the period from February 1 to April 28, causing 388 deaths.

PROFESSOR ROKITANSKY, of Vienna, has had the dignity of Baron conferred on him, as a Commander of the Imperial Austrian Order of Leopold.

HIPPOPHAGY.—During the first three months of 1874, 2,111 horses, asses, and mules, were killed for food in Paris. The number, in the corresponding periods of 1872 and 1870 were respectively, 1,275 and 989.

INFANT MORTALITY IN ST. PANCRAS WORKHOUSE.—The death-rate amongst the infants in St. Pancras Workhouse appears to have been exceptionally high during the past year. The inspector of the Local Government Board has reported that out of 407 infants in the workhouse under two years of age, no fewer than 89 had died, the mortality being at the rate of 218 per 1,000 per annum. The guardians have stated in their reply, by way of explanation, that there was in the workhouse a great number of deserted and previously neglected children, that some were brought up by hand, and that, as was well known, amongst such children the rate was always high. During the twelve months referred to, seven children died from the effects of wilful neglect and cold, previous to admission, and two from accidental causes. These deaths were therefore not due to ordinary causes. During four months of the year, measles of a severe form were prevalent among the children in the workhouse, and this also increased the death-rate.

THE MEDICAL PROFESSION IN AUSTRIA.—According to the latest data, the number of civil medical practitioners in Austria is 7,072, of whom 3,874 are doctors of medicine, and 3,198 surgeons. These are distributed as follows. In Lower Austria, 1,209 doctors and 619 surgeons, of whom 988 doctors and 79 surgeons are in Vienna; in Upper Austria, 121 doctors and 301 surgeons; in Salzburg, 32 doctors and 29 surgeons; in Bohemia, 1,014 doctors and 544 surgeons; in Galicia, 340 doctors and 369 surgeons; in Bukowina, 30 doctors and 38 surgeons; in Moravia, 229 doctors and 413 surgeons; in Styria, 213 doctors and 366 surgeons; in Tyrol, 351 doctors and 203 surgeons; in Silesia, 41 doctors and 96 surgeons; in Carinthia, 29 doctors and 99 surgeons; in Dalmatia, 85 doctors and 19 surgeons; in Trieste and the coast region, 81 doctors and 21 surgeons; in Carniola, 31 doctors and 61 surgeons; in Istria, 38 doctors and 12 surgeons; and in the county of Görz, 30 doctors and 8 surgeons. There are 2,354 military medical officers in the Austro-Hungarian monarchy, of whom 2,139 belong to the army, 63 to the marine force, and 152 to the Landwehr.

INTERMITTENT FILTRATION.—A recent report by Mr. Dyke, of Merthyr-Tydfil, contains an important passage in relation to the system of intermittent filtration. It has been suggested that when this system has been adopted for the disposal of sewage, the land will in time become clogged, and consequently less available for the purpose. So far, however, as Mr. Dyke's experience of the works at Merthyr-Tydfil goes, this does not appear to be the case. He says: 'I have recently tested the waters discharged from the sewage filtration-area at Troedyrhiw into the river Taff. The purified sewage is more free from pollution now than it was in July 1872, when it was shown to contain but 1 part of organic matter in 200,000. It is far purer than the water supplied to the inhabitants of Oxford, and to the householders in the neighbourhood of Lincoln's Inn Fields, in London.' This is strong evidence that no clogging of the soil has occurred in two years; for if its pores were occupied with organic matter, it is evident that the quality of the effluent water could not have improved.

ADULTERATION OF FOOD ACT.—At a meeting of the Midland Chemists' Association, the subject of the provisions of the Adulteration of Food Act was discussed, and it was determined to lay the following suggestions before the select Committee of the House of Commons, which has been appointed to consider the operation of the Act:—1. That in all cases the person buying goods for analysis shall divide the article into two portions, and shall hand over one portion, under seal, to the vendor for an independent analysis. 2. That referees shall be appointed by the Government, and that one of them should be a pharmaceutical chemist. 3. That in the case of an analyst reporting that an article is adulterated, which shall be proved to be genuine, the prosecutor shall be compelled to advertise the verdict in the newspapers in the district, so that the reputation of honest tradesmen may be protected. 4. That a guilty knowledge should be necessary to constitute an offence under the Act. 5. That, as it appears from a report of the examinations in committee that the members have an erroneous idea of the capabilities and respectability of the chemists in the country as compared with those in London, your memorialists suggest that one or more country druggists be examined before the Committee of the House of Commons.

EAU-DE-COLOGNE.—Dr. Chadwick, of Boston, while lately looking through the medical pamphlets preserved in the Boston City Library, came across an advertising circular entitled '*Vertus et Effets de l'excellente Eau admirable, ou Eau-de-Cologne, approuvée par la Faculté de Médecine, le 13 Janvier, 1727.*' From this it appears that eau-de-Cologne was originally concocted for a quack medicine. In the circular, which in type, paper, and language bears evidence of belonging to the last century, it is stated that this water was invented by an Italian, Signor Paul Feminis, an old distiller of Cologne.

It is described as a 'volatile spirit, extracted from the rarest and most delicate simples; an elixir which has the power of restoring the parts of the body that are attacked by any disease, or predisposition to the same, of fortifying and re-establishing their natural functions, of insinuating into them a moderate and living warmth, which, sympathising with their own, reanimates their vital forces, and aids the coctions.'

It seems to have been employed internally and externally, and to have been a sovereign remedy for apoplexy, paralysis, palpitation, obstructions of the liver, spleen, and kidneys, migraine, sore eyes, ringing in the ears, toothache, gout, burns, bruises, &c.

The virtues for which it has since become celebrated were apparently then thought to be unworthy of notice. From the history of this elixir the authors of quack medicines may, at least, learn the advantage of making them innocuous and sweet smelling; and when one thinks of the nauseous drenches and drastic combinations with which the million are now drenched by rival proprietors of pre-

tentious nastiness, whose eloquence is not less impressive than that of Jean-Marie Farina, of Cologne, and whose 'cautions' are not less solemn, it seems desirable that the old precedent should be revived. 'Opopanax' is not, we believe, announced as a rival of Holloway. But if the million must be quacked, and that seems to be still their desire and their destiny, the perfumer has an obvious advantage over the apothecary, which he seems to have forgotten.

A GOOD EXAMPLE.—The operation of the Adulteration Act in New York has given a great impetus to the consumption of milk in that city. According to the *Scientific American*, many restaurants have been established where the refreshments supplied are confined to a few simple articles of farinaceous food, and to bowls of milk and cream sold at moderate prices. The idea is said to have originated five years since with the proprietor of a small baker's shop in a humble locality, who had a monopoly of this kind of business for some time, and found it very profitable. Other persons, attracted by the rumours of his gains, opened larger establishments, which have culminated in full-blown restaurants. The more popular of these are said to be largely patronised by all classes. As much as 1,200 quarts on a cool day, and half as much more on a hot one, is the quantity of milk said to be consumed in a single establishment, by an average of 2,500 persons.

Since the penalties imposed by the Adulteration Act in London, and the vigilance of our milk analysts have rendered it possible to obtain pure and wholesome milk in the metropolis, it might be worth while to try an experiment of a similar kind. Milk, with the addition of aerated water and ice, forms a delicious and wholesome beverage in hot weather; and a most nutritious one in cooler weather, without the ice or aerated water. We see with pleasure that some milk shops in London are taking a step in the direction indicated, by selling milk and Apollinaris water by the glass at a low price.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.: free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

WEDNESDAY, JUNE 17, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

REUMONT ON CONSTITUTIONAL SYPHILIS AND ITS MIXED TREATMENT BY MINERAL WATERS AND MEDICINES.

(Concluded from page 354.)

Besides the forms of combined syphilis just mentioned, there are others which must be considered as the dregs of past syphilitic processes—such as squamous exanthemata, slight affections of the periosteum, and of the glands. In most cases of this kind, the mercurial cure would be tried without success. These are the comparatively rare cases, which may be cured by the bath-treatment alone. It is impossible to say whether such cases are caused by the mercury in the system being rendered soluble, and being thus eliminated, or by the increased rapidity of tissue-transformation enabling the system to get rid of the syphilitic poison. Indeed, it is always to be remembered that a certain number of syphilitic cases attain a natural cure, irrespectively of all treatment.

As already said, the bath-treatment is especially a valuable preparatory for further treatment. Patients come to the baths, who have been some of them weakened to a great degree by the persistent and fruitless continuation for years of antisymphilitic treatment, while others have lost all receptivity of the action of medicines. In such cases, the bath-treatment rouses the system by the quickened change of tissue, and by its influence on the activity of the skin, to a state which makes it capable of receiving further treatment with advantage, and enables a smaller amount of specific remedies to be effectual. Experience has shown that bath-treatment, assisted with the use of mercury or of iodide of potassium, is perhaps the most effective measure against constitutional syphilis, and often gives favourable and permanent results, when other modes of treatment have failed. What characterises this mixed treatment specially, is the comparatively easy, quick, and permanent cure, which can be obtained with a minimum appearance of mercurial symptoms, with preservation of the strength, and with an avoidance of all disagreeable mercurial symptoms after the cure of the syphilis is complete. As to the medicines to be used along with the bath-treatment, it is only natural that there should be some difference of opinion among bath-doctors, according to their experience and their views as to the operation of certain modes of treatment.

As regards the properties of iodine, especially the iodide of potassium, the excessive praise which used to be formerly bestowed on this medicine as an antagonist of syphilis, is no longer accorded it. According to the experience of Reumont, and of most bath doctors, the union of the iodide of potassium with the

bath-treatment is most advantageous, in cases where, after repeated courses of mercury, the system has lost its susceptibility for that mode of treatment, when the symptoms of mercurial outweigh those of syphilitic cachexia, or when other circumstances, such as scrofula, anæmia, or tuberculosis forbid the use of mercury. Sometimes some of these circumstances are present in so-named tertiary cases, against which the reputation of iodine has been so high. But even in these, in the newer and more irritative cases, it is often necessary to make use of mercury. However, iodide of potassium has a very marked beneficial action against syphilitic pains of the bones or of the muscles, on which account it is often administered after the mercury. The mercury-attracting power of the iodide, on which the anti-mercurialists lay much stress for their theory of mercurial disease of the bone, is more than doubtful, and we know from Waller's experiments that elimination of mercury may take place spontaneously.

In all other, especially in all the more recent cases of the constitutional disease, and in cases where there have been relapses after cures, mercurial preparations are employed along with the bath-treatment. And the daily experience of all doctors of sulphur-baths show this treatment to be uncommonly quick, sure, and mild. In this mode of treatment, apparently, Sigmond's modified inunction-cure is preferred to all others. It is of itself an excellent way of introducing mercury into the system; it is doubly so when supported by the subsidiary and alternative action of sulphur-waters. The sulphur-waters containing some amount of chloride of sodium are especially useful, as it is probable that, in inunction, the mercury acts as a compound salt of chloride of mercury and chloride of sodium, which is found present in the perspiration. We must not, however, deny to the sulphur-waters which contain carbonate of soda, a special value, owing to their saponifying action on the skin. Of other mercurial preparations, the next most used, but decidedly of a second rank, is the sublimate (both internally as Zittmann's decoction, and externally as an addition to baths); the two iodides of mercury are both very uncertain remedies. The injections of sublimate, highly recommended by Lewin, have been little used along with bath-treatment. So also mercurial fumigations.

Other besides sulphur-waters may be found useful in constitutional syphilis, either for preparatory or for after treatment, or in the case of some complications, even during the specific treatment. These are, especially, the salt springs, the wells containing iodine and bromine, the indifferent waters, and the cold-water cure. For the after-cure, the various climatic resorts are of service, and mild southern winter resorts are recommended.

These baths and health-resorts may render various modifications of the usual sulphur-bath treatment highly rational.

We shall next consider those syphilitic forms and those combinations of them which have been found by experience to be particularly suited to sulphur-bath treatment.

Apart from the multiple infiltration of glands, which is one of the earliest and one of the latest symptoms of syphilis, that poison localises itself earliest, most persistently, and most frequently in the skin and mucous membranes.

In all cases of syphilis of the skin (syphilides) the bath-treatment shows itself especially efficacious in its operation, both on the eruption itself, and on the

skin, which is disordered in function. Yet some selection may be made among sulphur-waters according to the degree of their exciting properties, as connected with the amount they contain of common salt, of soda, or of lime combinations.

Of Aix-la-Chapelle, which contains some common salt, it may be said that it is especially valuable in syphilides inclined to ulcerate. Rupia ulcers are sometimes closed completely within two or three weeks, simply by the use of protracted baths. Such closure or scarring over is indeed somewhat imperfect, and is not sufficient to make a more complete and specific treatment of the constitutional malady unnecessary. The slighter forms of syphilides, especially roseola, often disappear under the use of the waters alone, while some forms rather extend themselves. The commonest form of eruption that presents itself at baths for treatment is the syphilitic form of psoriasis; next come the papular forms, and syphilitic ulcers of the skin, especially those that have developed themselves from soft nodules.

On no other portion of the body, where syphilis shows itself frequently, is it more difficult to determine whether the affection is syphilitic or mercurial, than when it is seated in a mucous membrane, especially in the buccal cavity. Here the bath-treatment is most useful in diagnosis; for, if the affection be mercurial, it disappears tolerably rapidly under energetic use of the waters. At first sight, mercurial and syphilitic spots in the mucous membrane of the buccal cavity, with their great resemblance to each other, especially diffuse angina, and stomatitis with tendency to the formation of erosions and of flat ulcers, also papular growths of the mucous membrane, the result of them, which often accompany chronic mercurialism, indeed even aphthæ from gastric causes, may sometimes for a moment be deceptive. If in such cases there be no other syphilitic symptoms, the diagnosis is often very difficult. Among the syphilitic affections of the mucous membrane of the mouth and tongue, perhaps there are none so often set down to mercurialism, and sent to sulphur-waters accordingly, as the greyish white spots, the so-called *plaques opalines*, though they have nothing to do with mercury.

In the treatment of affections of the mucous membranes, much less use has been made of late years at sulphur-baths of iodine than of mercury. Iodine was indeed more used formerly, because many of these affections were supposed to be the result of mercury, or of a combination of mercury and syphilis. It is indeed true that iodine often removes mucous *plaques* rapidly, but they are apt to recur. A mixed iodine and mercurial treatment is often used successfully in the more distinctive forms of syphilitic affections of the mucous membranes. In oozæna such a combination is often useful; at least, mercury alone is often insufficient. No affection shows itself more obstinate against all treatment than the so-called *plaques opalines*, especially in their highest stage of development, keratosis, of which, however, it may be doubted how far it actually belongs to syphilis.

Next to the skin and mucous membranes, syphilis most frequently attacks the periosteum and the bones, and affections of this kind are frequently the subject of treatment at baths. It was exactly these cases that the antimercurelists had selected as proofs of the injurious influence of mercury, but which are now known to have no connection with that metal. From the careful studies of Overbeck and Kussmaul on the

action of mercury and from the pathologico-anatomical researches of Virchow, it is now placed beyond all doubt, that the affections of the bones of syphilitic patients are not the products of mercury but of syphilis; that there are no diseases of bone, which are expressions of the mercurial dyscrasy. That in mercurialism no affections of the bones are present, except occasional periostitis and necrosis of the jaw, in consequence of stomatitis. This result of research is of vast therapeutic importance. Although, then, the syphilitic nature of affections of the bones is quite ascertained, yet it is at the same time not to be denied that the untimely, careless, or excessive use of mercury without curing the disease, leads, by breaking down the constitution, to the production of the worse forms of syphilis, and among them, favours the generation of bone disease. Of other dyscrasies, scrofula appears especially to favour the production of disease of the bones—and rheumatism and gout also help. All forms of disease of the osseous system may be met with at baths—from slight periostitis to exudations on the periosteum and inflammation of the bone, resulting in tophi, hyperostosis, caries, and necrosis. As to the special treatment of these affections, it need merely be said here generally, that the favourable results are got from a combination of varied applications of the waters, including the sulphur *Schlamm* baths with the use of iodine and of mercurial inunction. The waters in such cases support in a wonderful degree the action of the mercury in the resolution and absorption of the new formations of the osseous system. The chief value of the iodine is, as Sigmund has remarked, as a narcotic for the pain in the bones.

Of other so-called tertiary forms of syphilis, orchitis is to be met with pretty frequently in Aix-la-Chapelle. Its treatment in tolerably recent cases, and when syphilides are also present, is usually by mercurial inunctions and the bath-treatment. In the older cases, iodine often answers along with the baths, but it is frequently necessary to have recourse to the mercury.

The cases of visceral syphilis under treatment appear to become every year more numerous; this is doubtless the result of pathological investigation going hand in hand with clinical observation, and recognising many of the chronic affections of the viscera to be of syphilitic nature. There were indeed formerly cases of hemiplegia and paraplegia, and peripheral loss of sensation, and neuralgia, which were attributed to syphilis. But now we treat syphilitic affections of the liver and lungs, and affections of the nervous centres which do not always lead to paralysis, but may show themselves as epileptic convulsions, giddiness, headache, weakness of memory, affections of speech, &c.

Syphilitic affections of the liver, now that they are better known, are frequently treated at Aix. Dr. Wetzlar has given an account of eighteen cases of waxy liver. He treated them with sulphur-waters, in combination with sublimate and frictions; and only in the cases where mercury had been previously used, with iodide of potassium. The result was favourable. Several cases of hepatitis gummosa, even in its most advanced stage, have been treated of late years by Dr. Reumont; they were sometimes associated with other syphilitic symptoms. They were treated with energetic friction along with the ordinary bath-treatment, and generally did well. Wider experience of such cases is required, but there need be little doubt that in some of them the relation of sulphur-

waters to the liver must be of value; that is, their ascertained action on that organ.

Syphilitic phthisis developed out of chronic lobular pneumonia is sometimes treated in sulphur-baths. Grandidier gives an account of a case of that kind, which the drinking of the Nenndorf water along with iodide of potassium cured. A second case, with which asthma was associated, was cured in Nenndorf with sulphur-baths, inhalations, and inunction. Dr. Reumont has treated two characteristic cases, in which the smaller bronchial tubes and the sternum were affected, successfully by combined thermal and inunction cure. The syphilitic affections of the nervous system, above enumerated, are often treated at Aix. As to the etiology of such cases, it is very often difficult to determine what share mercury or rheumatism may have had—undoubtedly they were often predisposing causes to the affection of the nervous system. In these cases the combined treatment by sulphur-waters and inunction, with the intercurrent use of iodide and bromide of potassium, have frequently produced improvement, in some instances cure. It is obvious that in most such cases, especially when there is any congestive condition, the baths must be used carefully and with moderation. They act at once by improving the general state of the system, and also locally on the part affected, relieving the relaxation of the muscles and the rheumatic pains.

[The great characteristic of the bath-treatment as pursued at Aix is the inunction of mercurial ointment. This is carried on there to a great extent, most, perhaps by Dr. Brandis. It is surprising how little salivation occurs. Dr. Brandis employs acetate of alumina against it, as the French do chlorate of potass in the form of pastilles. The reporter has reason to regard the treatment of constitutional syphilis at Aix as very successful. Several cases of rupia and ecthyma, and of exostosis, and of the two combined, have recovered rapidly, and remained well at least for three or four years, and up to the present date. Warm bathing is the most important part of the balneological treatment, and it is very possible that the Germans attribute too much to the presence of minute quantities of chloride of sodium in their waters, as French do the presence of the sulphide of sodium or of its silicate. They very possibly both overvalue the test properties of their waters.]

The results of hydrotherapy confirm the view of the important share in the cure taken by the baths. The late intelligent Dr. Petri never saw more than passing benefit from simple hydropathic treatment in pustular, tubercular, or ulcerating syphilides, or in affections of the bones, or of the internal organs; whereas, like the late Fleury, he found treatment by inunction of iodine, when combined with hydrotherapeutic treatment, most efficient.

It would seem that all use of baths operates efficaciously, so far as it stimulates the system, quickens the transformation of tissue, and acts on the skin—the skin and the system generally acquiring increased receptivity of medicines, whether applied externally or internally. Practically, the reporter believes that constitutional syphilis can be treated most successfully at thermal baths having excellent local arrangements, such as Aix-la-Chapelle, Luchon, Cauterets, and others.—*Rep.*] J. MACPHERSON, M.D.

ON THE USE OF ZINCED OR GALVANISED IRON FOR THE STORAGE AND CONVEYANCE OF DRINKING-WATER. BY W. E. BOARDMAN, M.D., OF BOSTON.*

(Continued from page 361.)

2. We come now to the consideration of our second inquiry; namely, Do the products, resulting from the action of ordinary drinking-water upon the zinc of galvanised iron, exert a poisonous action upon the human system?

In this inquiry, it seems unnecessary to take into consideration such extraordinary idiosyncrasies as are shown sometimes, in the inability of individuals to take iron in any form, even in small amounts, or to receive the perfume of a rose without causing asthma. It is not to be denied that a similar extreme susceptibility to some property of zinc may be the occasion of analogous effects.

It is to be premised, also, that we are not to include in our conclusions the results which may be due to water unfit for drinking purposes, and which may contain ingredients that would act energetically upon zinc, and contain an unusually large amount of the soluble compounds of this metal.

We have, then, to consider the effects of the oxide, the carbonate, and the compounds which occur in solution.

The oxide of zinc, first prepared by Hellot, in 1735, has been employed extensively since his time, both as a medicine and in the arts. Most authorities assert that it is innocuous, while some entertain suspicions of, or attempt to prove, its poisonous character.

J. Johnstone, † not including zinc among the mineral poisons, relates, from his own experience, that ten grains of the oxide, taken daily for more than three weeks, were innocuous in the case of a boy about fourteen years of age.

MM. Vauquelin and Deyeux, ‡ on the ground that the oxide, resulting from the action of potable water, is not injurious, recommended the use of zinc in the manufacture of reservoirs and water-pipes. This opinion was confirmed by Devaux and Dejaer, § and, a few years later, Orfila § expressed a similar conviction. MM. Merat and Lens, || after enumerating the various uses to which this oxide may be put, remark, 'Some writers state that it sometimes gives rise to colic, a phenomenon which we have never observed.' They refer, also, to authorities, cited by J. F. Gmelin, ¶ who ascribe to it an irritant action, 'which, we believe, is not a fact.' Christison ** makes no reference to any injurious results from the internal use of this oxide, except that he coincides with Orfila, in his estimation of the results obtained by MM. Vauquelin and Deyeux. He also remarks, that 'it does not appear that workmen, who are exposed to the fumes of zinc, ever suffer materially.' Heller †† went so far as to state that this oxide might be given up altogether as a medicine, since,

†† *Archiv. f. Physiol. Heilk.* 1847.

being insoluble, it passes through the intestinal canal as inert matter.

M. Blandet* reported cases of supposed poisoning by the fumes of the oxide of zinc. MM. Guerard† and Levy‡ and others, denying the connection of cause and effect in these cases, coincide in the statement that analogous accidents do not ensue from the internal administration of this compound. M. Bouchut,§ in an elaborate memoir to the French Academy of Sciences, gives an account of the action of oxide of zinc upon the human system. He says, in doses of one to six grammes daily it never occasioned any gastric disturbance; occasionally it gave rise to sleeplessness and restlessness at night. He gives, also, a critical analysis of the classical cases of supposed poisoning by the oxide, which were reported by Blandet in 1844, Bouvier, Landouzy, and Maumené in 1850, and shows conclusively that the ill effects in these instances were due to other causes.

In a review of the last-mentioned paper, M. Chevallier|| confirms the opinions of M. Bouchut, and concludes that the oxide of zinc is incapable of producing death, or even of causing any serious effects. He also calls attention to the observations by Michaëlis of Tubingen,¶ who stated that he occasioned the death of dogs with daily doses of a few grains of the oxide, a result contrary to those obtained by MM. Flandin,** Orfila,†† and Bouchut.§ M. Bouchut repeated the experiments upon which Michaëlis founded his opinion, but with negative results.

Pereira‡‡ remarks that this oxide may be taken, in small doses, for a considerable period, without causing any obvious effects; in large doses it sometimes causes temporary giddiness and inebriation. By long-continued use, however, he says, it acts as a slow poison; in proof of which he cites a case|||| where twenty grains were taken daily for about five months. Rapid recovery, however, ensued as soon as the administration of the drug was discontinued. He refers, also, to the cases mentioned above, which were confuted by M. Bouchut and others.

Tardieu states explicitly that zinc imparts no poisonous qualities to water—a fact which has been proved by theory and confirmed by experience. He refers to facts cited by M. Boutigny,¶¶ who attributed poisonous qualities to water collected in zinc reservoirs, and remarks that they have not been confirmed and must be regarded as absolutely exceptional, and, without doubt, were due to some special accidental circumstances.

Oesterlen*** states that the action of this oxide, when taken internally, is very slight, even in large doses, and expresses his doubts as to the efficacy of the drug, so long accepted, in various diseases. When given to patients in large doses, or for a long period, he says, it may give rise to unpleasant symptoms; yet 'patients in the Paris hospitals have recently taken

one to two ounces daily, and Trousseau* has given ten grains and more, daily, to young children, even without perceiving any deleterious effects.'

Schlossberger,† Michaëlis‡ and others have detected the presence of the metal in several of the secretions of the body. Van Hasselt§ confirms these facts, and asserts that all compounds of zinc, when introduced into the stomach, are transformed immediately into albuminates, in which form they enter the circulation. He gives his assent to the occasional production of what he terms 'zinc-dyscrasia,' referring to the above cases reported by Pereira. In regard to the cases reported by Blandet (see above), and similar ones by Becquerel, Elfes, and Rust, however, he coincides with the more general view, that they were probably due to other causes, which conclusion, he remarks, is all the more probable from the fact that the symptoms disappeared rapidly on the removal of the supposed cause. The same argument might, with reason, have been applied by himself to the cases which he cites from Pereira in proof of the actual occurrence of 'zinc-dyscrasia.'

Dr. Herpin|| remarks, 'The oxide of zinc is perfectly harmless, and may be administered even in doses of six grammes daily, which may be continued for any length of time.'

Greenhow¶ mentions a case of what he terms 'brassfounders' ague,' which, he says, is occasioned by the fumes of deflagrating zinc. These fumes are zinc vaporised in a metallic state, and changed into the oxide by contact with the air.** This case was similar to those reported by Blandet and others, to which we have already referred, the conclusions in all of which were shown to be erroneous.

Stillé,†† after citing several reported instances of the ill-effects of this oxide, remarks: 'Yet effects of this kind cannot be of ordinary occurrence, for we find that Home‡‡ sometimes gave as much as forty grains a day without injury; that Sieveking cured a case of epilepsy in which thirty-six grains of the medicine were taken three times a day, without any unpleasant effect whatever.'§§ He refers, also, to the opinions expressed by Dr. Herpin, and quoted above.

MM. Bouchardat and Fonssagrives,‡ also, have shown that the oxide which may be contained in drinking-water is innocuous.

Wood and Bache,||| referring to reported cases of zinc colic,¶¶ remark: 'This statement, is, however, is to say the least, very questionable.'

Hirt*** remarks that some workers in zinc are liable to the ordinary affections to which founders and metal-workers generally are exposed, but that specific effects of zinc (referring to the oxide) have never been proved; that the digestive organs are not affected in the least, a fact upon which he satisfied

himself by very extensive observations and inquiries.

Dr. Winsor,* of Winchester, Massachusetts, in a recent report, states that it is neither plain, nor is it at all probable, that any person has been in any way poisoned by drinking-water which is impregnated with zinc, in the form of oxide or carbonate. In this opinion, he observes, he is confirmed by inquiry made of skilled analytical chemists, of experts in materia medica and toxicology, manufacturers of zinc pipes, house-painters, and others.

The board of water-commissioners of Melrose, Massachusetts, in 1871, issued an official circular to 'Spot Pond Water-Takers in Melrose,' in which they urged the immediate removal, or the discontinuance of the use, of galvanised iron service-pipes. The immediate cause of this action on the part of the commissioners seems to have been the occurrence of some cases of sickness, one proving fatal, in the family of the chairman of the board.† The attending medical adviser of the family pronounced them to be cases of zinc-poisoning, and J. R. Nichols & Co., of Boston, assent to this opinion, having made an analysis of this water drawn through and confined around zinc pipes. In this analysis they state the amounts of oxide and carbonate of zinc found in the specimens, and remark: 'It is proved by our investigations that the use of galvanised iron service-pipes in conducting Spot Pond water is highly dangerous to health, and should under no circumstance be permitted.' An associate of the medical attendant in the above-mentioned cases made a *post mortem* examination in the fatal case, and reported that he found evidences peculiar to zinc-poisoning, though he does not state what these appearances were. As no other fatal case is on record, the accuracy of observation, in this instance, may, with good reasons, be questioned. The history of the cases alluded to does not furnish evidence adequate to establish the correctness of the opinion given as to the nature of the illness, in the way of cause and effect.

In another case, communicated by Dr. Bronson, of Attleborough, Massachusetts,‡ the indefinite symptoms, presented in the report, would point as well to other causes as to mineral poisoning. It seems impossible that in less than two months—the period in this instance—symptoms such as described could have been developed by the comparatively small amount of the metal which would be received into the system from the water. Having in mind the variously confirmed facts which are presented in this paper, it must be said of this case, as of the others, that the conclusions are untenable.

From this *résumé* of opinions and facts, it may confidently be asserted, that the oxide of zinc, as it occurs in drinking-water, is absolutely harmless.

(To be continued.)

ANATOMY AND PHYSIOLOGY.

VULPIAN ON THE MOVEMENTS OF THE HEART. Dr. Vulpian (*Gazette Hebdomadaire de Médecine et de Chirurgie*, May 8, 1874) administered curare to a dog

and then opened the chest, exposing the heart. The movements were too rapid to obtain any exact data of the contractions of the cardiac cavities; he therefore passed a gentle current of electricity by means of an induction instrument. As soon as the rheophores were applied to the pneumogastric nerves, the heart stopped. 'It stopped at the diastole.' The auricle was distended, the rheophores were removed, and immediately the auricle was emptied and the ventricle contracted. In order to diminish the rapidity of the beats, an infusion of about 25 centigrammes of the leaves of digitalis was injected into the left femoral vein, and was repeated till 90 centigrammes had been used. The effect on the heart was slight at first; gradually the movements became slower, and after each diastole there was a long pause. Electricity was again applied to the pneumogastric nerves, and the combined actions carefully noted. The following were the conclusions obtained.

1. The auricles in mammalia have a very distinct unmistakable systolic movement, which immediately precedes the systolic movement of the ventricles.
2. There can be several contractions of the auricles to one of the ventricles.
3. The revolution of the heart begins with the systole of the auricle, and finishes with the diastole of the ventricle.

PARROT ON NEWBORN INFANTS.—In a clinical lecture delivered at the Hospice des Enfants Assistés, May 6, 1874, M. Parrot (*Gazette Hebdomadaire de Méd. et de Chir.* May 8, 1874), defined the expression new-born infants as indicating a child, viable or non-viable, born at full term or not, but not having exceeded the age of six weeks. Up to that age, the pathology is the same, the diseases undergo the same changes, and it is the period of certain physiological modifications effected after birth.

A fœtus differs from an infant in early life chiefly in the circulation. By respiration the external air is sucked into the meshes of the lungs, to be brought into contact with the blood upon which it has to act. The umbilical cord, the ductus arteriosus, and the foramen ovale, now no longer have a part to play, and gradually become obliterated. The cord dries up, and is thrown off between the fifth and sixth days. The stronger the child, the more rapid is this process. The intra-abdominal portion retracts and is obliterated in the vast majority of cases without any accident; but under certain conditions and in exceptional cases, it is the starting-point of a phlegmasia of the veins to the great danger of the infant. At birth it is not uncommon to find the foramen ovale presenting an ovoid aperture. Generally, at birth or a few days afterwards, the anterior border of the valve extends beyond the margin of the foramen ovale; but its closure is not always complete, and the admixture of the two kinds of blood is still possible under certain circumstances and conditions. In the left auricle, the orifice of the canal which takes the place of the foramen ovale is situated at the anterior and inferior part, between the two pillars which limit the valve.

Alvarenga found the foramen ovale only completely closed in eight cases out of 243 infants, between the ages of one day and a year. M. Parrot, in sixty-two children from one day to two years old, found the foramen closed in only four children. In adult life the proportion is no longer the same. M. Parrot examined fifty-two hearts, from the age of nineteen years to seventy-five; the sexes were about equal. In twenty-six cases he found the foramen still patent.

† *Boston Journal of Chemistry*, vol. v. 1871.

‡ *Boston Med. and Surg. Jour.* vol. viii. p. 189. 1871.

This persistence of the foramen he believes to depend on the position of the two orifices. It results from this arrangement, that when the blood tries to flow from the left auricle to the right, it finds an insurmountable barrier; and even when the opening is not closed it is very probable that the pressure on each side is equal, so that no mingling of the two bloods can take place. If from some cause the equilibrium be destroyed, as when the pressure on the right side of the heart is increased, the blood flows into all accessible parts, and the foramen ovale performs probably a very important part. Organic diseases of the heart, of the respiratory organs, and ailments from cardiac enervation, frequently produce this result. It is probably the repeated action of these causes, compelling the blood frequently to go the reverse way, that keeps the orifice open; and to this cause may be attributed the non-obliteration of the foramen ovale in the majority of cases. The author found the ductus arteriosus obliterated thirty times out of thirty-six. A valve placed at the orifice of the canal in the aorta prevents the passage of blood backwards, and it early becomes obliterated.

W. C. GRIGG, M.D.

ARLOING AND TRIPIER ON THE PERSISTENCE OF SENSIBILITY IN THE PERIPHERIC ENDS OF CUT NERVES.—At a recent meeting of the French Academy (May 25) the authors described some experiments (on horses, asses, and mules chiefly), in reference to this subject. The following is their *résumé* of results.

1. The facial and the spinal nerves of solipeds and rodents possess recurrent sensibility as well as those of carnivora.

2. To find recurrent sensibility most readily, one must go to the periphery.

3. The peripheric end of the branches of the trigeminus nerve is sensible. This sensibility is somewhat difficult to demonstrate; still it exists.

4. The peripheric end of the nerves of limbs is also sensible. The sensibility may, however, disappear towards the nerve-trunks.

5. In any case, the sensibility of the peripheric end is due to the presence of nerve-tubes, the relations of which with the trophic and perceptive centres have not been interrupted by the section.

6. The absence of these tubes implies insensibility of the peripheric end.

7. These tubes proceed from the fifth pair, for the facial; from neighbouring nerves, and occasionally from nerves of the opposite side, for sensitive nerves; from neighbouring and homologous nerves, for the mixed nerves.

8. These recurrent nerves rise more or less high in the trunk of the nerve to which they are connected; their number diminishes from the periphery to the centre.

9. The return of these fibres may take place before the termination of the nerves, but the termination is the part where it is made by preference.

10. For several reasons, MM. Arloing and Tripier think that the sensibility of the peripheric end belongs to all nerves; and that it probably exists in all animals of the class mammalia at least.

ALEX. B. MACDOWALL.

SLAVJANSKY ON RETROGRESSION OF THE GRAAFIAN FOLLICLES.—Slavjansky (*Archives de Physiol.*, 1874, p. 213), in Ranvier's Laboratory, has investigated some points in connection with the

anatomy and physiology of the ovary in the human subject. He sums up the results of his researches thus. 1. The Graafian follicles are developed from the primordial follicles, and acquire a greater or less degree of maturity during the whole of life, from the first month after birth till about the age of forty. 2. The greater part of the follicles are not ripe, do not burst, and do not discharge their contents, but undergo atresia, presenting an almost complete analogy with that of the formation of the corpora lutea. 3. The development and maturation of the Graafian follicles are not produced periodically in a regular manner, and no connexion exists between them and menstruation. 4. Menstruation constitutes a physiological phenomenon, quite independent of the development and maturation of the follicles. 5. The rupture of follicles more or less mature always bears a certain relation to congestions of the genital organs, produced by any cause whatever. 6. There exist certain maladies (ague, poisonings, &c.), which produce atresia of the follicles at different periods of their development, after a parenchymatous inflammation of the ovary.

PATHOLOGY.

WALDEYER ON RETROPERITONEAL HERNIA, AND THE ANATOMY OF THE PERITONEUM.—Professor Waldeyer, of Breslau, republishes in Virchow's *Archiv*, Band lx. Heft 1, a pamphlet originally written for private circulation in 1868.

Retroperitoneal Hernia.—In the *post mortem* examination of a robust man who died of double pneumonia at the age of forty, there was found a perfectly developed retroperitoneal hernia, which comprised the whole of the small intestines. Since the publication of Treitz's classical monograph (*Hernia retroperitonealis, ein Beitrag zur Geschichte der innern Hernien*, Prag, 1837) but few such cases have been described.* In this case the colon occupied its normal position. The great omentum, rather fatter than usual, concealed the small intestines; when this was reflected, it was seen that the coils of bowel were enclosed in a rather thick whitish sac, which included the whole mass of the small intestine.

* The author refers to Gruber, *Petersburg. Medizin. Zeitschrift*, 1861, and Virchow's *Archiv*, Band xlv. S. 215, for reports or reference to thirty-seven cases; also to three described by Eppinger lately (*Prager Vierteljahrschrift*, Band cviii. 1870); which, with the one above, make forty-one cases of retroperitoneal hernia already recorded. He does not seem to have noticed Dr. Biesiadecki's cases (see a report by Dr. Pye-Smith in LONDON MEDICAL RECORD, vol. i. no. 15, p. 233), or Kundrat's (referred to in LONDON MEDICAL RECORD, vol. i. no. 13, p. 199); nor is it clear that he includes Dr. Pye-Smith's two cases in *Guy's Hospital Reports*, 3rd series, vol. xvi.—*Rep.*

This sac had both the appearance and the structure of serous membrane, and was closely connected on all sides with the parietal peritoneum of the posterior wall of the abdomen, as well as with the peritoneum of the ascending and descending colon, its structure and texture being identical. It had numerous vessels of its own, with ramifying fat; it was quite transparent, and free from any signs of peritonitis. A median incision made it easy to remove the mass of intestines. The mesentery was quite normal. From the interior of the sac, it was easy to discover that its neck (*Bruchpforte*) corresponded to a point very nearly opposite the cæcum; the lower end of the ileum passed through this, and dragged upon the cæcum. The opening was nearly circular, as large as a two-thaler piece; its edges slightly thickened. The inferior mesenteric vein arched over the upper edge and free border of the opening. There were no signs of strangulation, and the coils of bowel could be easily drawn into and out of the sac. This case was a complete retroperitoneal hernia of the kind described by Treitz (*loc. cit.* p. 27) in his fifth case. The bowel had forced its way into the duodeno-jejunal fossa, and had gradually pushed the right fold of the descending mesocolon before it, and thus formed a sac for itself. The neck of the sac had originally lain higher, at the junction of the duodenum with the jejunum, and had thus been forced lower and lower with the weight of the mass. Waldeyer thinks the inferior mesenteric vein might easily have given rise to a constricting ring at the neck of the sac.

The Anatomy of the Retroperitoneal Fossæ.—The author adheres to the original and distinctive names of (1) fossa duodeno-jejunalis, (2) fossa intersigmoidea, and (3) fossa subcæcalis of Huschke and Treitz, in preference to the longer appellations of Wenzel Gruber (*Medizinische Zeitschrift Russlands*, 1859, no. 8). He has carefully examined 45 bodies of both sexes, varying in age from twelve weeks (of intra-uterine life) to sixty years. In 18 bodies the fossa duodeno-jejunalis was well developed, without hernia, in one with complete hernia; in 8 it was obliterated, yet clearly recognisable; in 18 it could not be demonstrated—of these, however, 10 were very young embryos, in whom the pouches were yet undeveloped. In 34 bodies the fossa intersigmoidea was well developed, without hernia; in 4 it was obliterated, but clearly demonstrable; in 7 it could not be demonstrated. This form is therefore the commonest; the fossa subcæcalis is much rarer. As regards adults, he finds the percentage in 250 subjects to be nearly as follows: fossa duodeno-jejunalis, 73 per cent.; fossa intersigmoidea, 84–85 per cent.; fossa subcæcalis, 30 per cent. These numbers agree very nearly with those of Treitz and Gruber. The fossa duodeno-jejunalis is practically the most important of the peritoneal pouches, as it most frequently gives rise to internal herniæ. Its site is exactly the part where the duodenum joins the jejunum; the bowel lifts itself from the vertebral column, and receives its own mesentery. It is funnel-shaped, and its blind extremity extends outwards on the left border of the duodenum, lying deep between this and the aorta. Gruber (*Archiv für Anatomie und Physiologie*, 1862, and Virchow's *Archiv*, Band xlv.) has described three cases of this fossa being situated on the right side, with a common mesentery for large and small intestine. In one of these cases there was a retroperitoneal hernia on the right side. Its usual size is about that of the top joint of a finger,

but it may reach dimensions which will easily admit a coil of intestine 1 or 1½ foot long. If traction be made on the first part of the jejunum, in a direction forwards, and to the right, the two peritoneal folds round the opening of this fossa will be seen like the plicæ Douglassii. [Two illustrative cases are appended.] This fossa may sometimes be divided into two, as in a male aged forty, dissected by Waldeyer; and sometimes there is another little pouch (*Vortasche*) in front of it. [A case is appended, in a male aged forty-five, in which this anterior pouch would conveniently hold four or five inches of intestine.] The duodeno-jejunal fossa, as noted above, is often quite obliterated.

The fossa intersigmoidea has had several discoverers (Hensing, Treitz, and W. Roser), and is situated in the mesentery of the sigmoid flexure. Its opening is in the lower fold of the mesentery, and the fossa lies between the two folds of mesentery, very close to the sigmoid flexure. If the latter be raised, so that its mesentery is put on the stretch, the opening of the fossa is easily seen, and in the author's experience, this is the most constantly present of all the peritoneal pouches. Treitz says that the inferior situation of the opening prevents herniæ from occurring at this spot. The opening of the fossa is generally slit-like, with a sort of valve formed by the upper border projecting—the fossa usually admits the tip of the index-finger. Its size varies. [Two cases are given, in one of which three fingers could be contained—in the other the opening was 2 by 1 inches, nearly.] It is very common to find a canal ($\frac{3}{8}$ to 1 inch deep) instead of a fossa—or there may be two such canals or pouches. [Illustrative cases are given.] The edges of the fossa are often very hard and thickened.

The peritoneal pouch of the cæcum, or so-called fossa subcæcalis (Treitz) is very rare. Yet two or three such pouches are described by Huschke, Treitz, Luschka, Langer, Schott, and Gruber. The author, from investigations made on the bodies of about 40 adults and 25 new-born children and embryos, concludes that there are at least four such pouches belonging to the cæcum—viz., (1) a fossa ileo-cæcalis superior (Luschka); (2) fossa ileo-cæcalis inferior (Huschke) = recessus ileo-cæcalis (of Luschka); (3) the fossa cæcalis (Huschke); and (4) the fossa subcæcalis (Treitz). A description of these is appended, with illustrative cases; together with the author's views as to the development of these pouches in the embryo. W. BATHURST WOODMAN, M.D.

DISEASES OF CHILDREN.

RAFINESQUE ON INFANTILE SYPHILIS.—M. Rafinesque (*Archives de Tocologie*, January, 1874) agrees with M. Trousseau that there is nothing which presents more difficulties in arriving at a correct conclusion than congenital syphilis. Although the influence of syphilis in causing abortion is admitted by all authors, yet the degrees of its frequency, the conditions favourable and unfavourable, and the period at which it most frequently occurs, have not been definitely determined. M. Rafinesque gives some

useful statistics bearing on these points from observations obtained at the Lourcine.

There were 44 accouchements of women tainted with syphilis, of whom 29 had children at full time, and 15 abortions. These figures differ considerably from Whitehead's—117 miscarriages out of 256 births; and from those of M. Fournier—141 premature to 249 deliveries at full time.

The period at which the abortions occurred were half at eight months, the rest at the fifth and sixth month; one only at the fourth month. Two others might not improperly be added to the list of miscarriages, although the fœtuses were delivered at full time, as they were in a state of decomposition, showing that death had taken place some time previously to their expulsion.

It used to be considered that the majority of these abortions occurred at the fourth month; but Lance-reaux placed them at the sixth or seventh month; the author, from his own observations, places them still nearer to term.

From the few cases in which he proved the father to be syphilitic as well as the mother, the effect on the period at which the abortion happened bore out the investigation of Bärenspring, that it was earlier. As to influence which the date of the contagion, during pregnancy, had on the child, he was unable, from the exceeding difficulties surrounding the inquiry, to obtain a sufficient number of cases to form a fair comparison. But the few which he did procure went to confirm the opinion of Trousseau and Diday, that syphilis contracted during gestation is not transmissible to the fœtus.

Where the father was healthy but the mother diseased, the delivery took place at the eighth month or at full time. In every case the child was affected; still the author believes that an infected mother may bear a healthy child, and that syphilis differs in no respect in this particular from other hereditary disorders.

May a syphilitic father beget an infected child, the mother remaining quite free? M. Rafinesque relates one case, but it is far from conclusive, as the infant did not exhibit any signs until it was six months old, and had in the meantime been suckled by two infected women for a month. The date at which hereditary syphilis generally first shows itself, from the observations made, coincided with M. Trousseau's. The period is within fourteen and forty days; it rarely appears before that time, and still more rarely after the eighth month. The most frequent form of the disease was *plaques muqueuses*; next in order of frequency came papular and papulo-squamous syphilides. *Post mortem* examination did not reveal the immediate causes of death; perhaps the microscope will give better results. The placenta was examined in every case, and showed no syphilitic lesions.

An antisyphilitic treatment of the mother did not seem to exert any beneficial influence on the child that should be born. In seventeen cases of abortion, the mother had been under treatment not less than fourteen times; ten for a considerable period, and three no treatment whatever. In the last cases the children were born at the fifth and seventh month, and at term. On the other hand, of twenty-seven women who were delivered at full time, nine only had undergone any specific treatment for not more than three weeks, six had been treated from ten days to three weeks before confinement, eight had done nothing, and the last four seemed to be in a similar condition. He agrees with M. Fournier and others,

that syphilis seems to act not injuriously on parturition, but on the contrary, obstinate *plaques muqueuses* of the vulva have been seen not unfrequently to rapidly disappear during child-bed.

W. C. GRIGG, M.D.

WERNICH ON COCCYGEAL TUMOUR IN A CHILD. At the meeting of the Gynæcological Society of Berlin, on November 25, Dr. Wernich exhibited a child two years old with a large coccygeal tumour. Its greatest circumference was $27\frac{1}{2}$ inches; it was hard at the base, but fluctuating at the apex. The resistance felt in the abdomen seemed to show that it probably extended into the pelvis. The child could walk tolerably rapidly in a bent position. Fœtal remains could not be felt within on the tumour; it seemed rather to consist of cysts with isolated patches of lipoma.

SURGERY.

COUSIN ON RESECTION OF THE SHAFTS OF THE LONG BONES AFTER GUNSHOT INJURY. — Dr. Cousin (*Union Médicale*, January 17 and 24, 1874) enters into a minute historical criticism of the opinions held upon this subject, and quotes, in the first place, from the often cited Circular no. 6, that resection of the long bones in their continuity in the treatment of gunshot fractures, is an operation to be condemned. These fractures are generally comminuted, and from the mere extraction of loose fragments to the total formal resection of the injured part, the difference is only one of degree. Percy recommended the irregular broken ends of the bone to be sawn square; and Baudens, during the Algerian wars, adopted this plan for the upper limbs. He speaks very hopelessly of the effort to save the limb in fracture of the thigh. Larrey most strongly objected to the resection of the ends of the fractured bone, and certainly the experience of recent wars has amply justified his objection. German, French, and Italian surgeons, have all found their efforts in this direction failures. Such operations are generally useless, if immediate; rarely indicated, and rarely successful when intermediate; at later periods, however, when the bone has become necrosed, they are often demanded, and when performed, are generally followed by satisfactory results. The conditions under which the operation is then undertaken resemble those in an ordinary case of necrosis.

Resection, therefore, of the long bones, in their continuity, after gunshot-wounds may, in general, be considered a bad operation. It is rare in time of war that conditions favourable for such an operation exist; amputation is better than resection, in that it requires a shorter time for recovery, and patients so treated reach much more easily, and much earlier, a condition fit for transport. The majority of wounds will heal when the patients are young, healthy, well treated, and placed in good hygienic conditions. Young soldiers, therefore, are better able, when the wounded are not too much crowded, to withstand the effects of severe operations. Resections in the continuity afford better results in the upper than in the lower limb; they are practicable, perhaps, in the leg,

but should be rejected entirely in the thigh. If the bony fragments be numerous and large, and the fractured bone-ends difficult to keep in position, if the periosteum be largely separated, or if there be fissures, resection may be practised when there is nothing in the condition of the soft parts to contraindicate it. It must not be forgotten that a limb thus resected requires more attention than one treated conservatively. The wound is increased in extent, the retention of the limb in proper position becomes exceedingly difficult. Even if osseous suture be practised; and the operation be done subperiosteally, there is sure to be much shortening, and perhaps a false joint. If the operation be indicated, it is clear that it cannot be done with advantage in the primary stage; the limb must either be treated conservatively or be amputated. In the secondary period, when the inflammatory symptoms have subsided and the suppuration is well established, the operation becomes practicable, the periosteum is vascular and thickened, easily separable, and its powers of regeneration much increased; but an almost insurmountable objection exists in the impossibility of determining the limits of the osteomyelitic inflammation in the bone; it often extends higher than the changes in the periosteum would indicate. Even could this be determined beforehand, sawing through the bone is very likely of itself to start the inflammation afresh. At a later period, some months after the injury, when fistulous tracks exist, leading to sequestra, an operation for their removal affords, of course, excellent results.

WILLIAM MAC CORMAC.

VERNEUIL ON THE PALLIATIVE TREATMENT OF CANCER OF THE RECTUM BY LINEAR RECTOTOMY. M. Verneuil, in a lecture given at the La Pitié Hospital, and reported in the *Gazette Hebdomadaire*, March 27, 1874, has demonstrated the advantages which may be derived from linear rectotomy in cancer of the rectum. Besides the three cases he published in a memoir, read at the Société de Chirurgie in 1872, he has since performed this operation in two other cases, with the effect of removing the pain and giving great relief. Up to that time rectotomy had been performed with the linear *écraseur* in the posterior median line, and as high as possible. In the fourth case, which formed the subject of M. Verneuil's lecture, he resected a small band about two centimètres wide, along the posterior wall of the rectum. To facilitate this operation, M. Verneuil cut a triangular piece of skin, of which the base corresponded to the point of the coccyx and the apex to the posterior commissure of the anus; this strip largely opens the postrectal cellular cavity, and allows the operator perfect freedom of working on the exposed rectum.

SEBILLE ON GOUGING AND SUBPERIOSTEAL RESECTION OF BONE.—After having passed in review the different facts cited in support of both methods, Dr. Seville more particularly gives his attention to two cases in which resection has been successfully performed by M. Richet, and arrives at the following conclusions, published in the *Thèses de Paris*, 1874. The plan of gouging benefits, in our opinion, by the remarks and criticisms which it has been in our power to make on subperiosteal resection. In surgery it is necessary to be able to see what one is doing, and to have free scope for action. In this respect the surgeon is at his ease, since the principle of the method is to eliminate all the un-

sound portions of the bone. We do not deny that large experience is necessary, so as to stay one's hand at the proper time; therefore we do not recommend this operation to a young surgeon who is not perfectly well informed on the histological elements appertaining to affections of the bones. It is a remarkable circumstance that the member operated on should not become the seat of any inflammatory reaction. During the first few days, the integumentary fragments become swollen and then cleanse themselves, while the wound in the bone becomes covered with fleshy excrescences. Sometimes the bony surfaces which have been gouged are attacked by partial necrosis, and thin laminae thus produced are rapidly detached.

Ollier had laid hold of this fact for the purpose of laying a serious indictment against gouging; but experience has proved that this incident does not hinder cure; it is only a matter of time. The gouging plan, according to Dr. Seville, possesses advantages over subperiosteal resection which may be thus enumerated.

1. Free issue is given to the liquids resulting from diffuse and infectious inflammation, ulceration, gangrene, pyæmia, &c.
2. The shape and the length of the member are retained.
3. The muscular, tendinous, ligamentous, and aponeurotic attachments are preserved intact.
4. By comprehending in the incision the fistulous passages which permeate the bone and the diseased parts, and cauterising them, a perpetual source of suppuration is dried up, and the patients are frequently restored to health.

OLLIER AND OTHERS ON RHINOPLASTY BY A NEW METHOD.—In the *Union Médicale* of April 25, 1874, is the account of a discussion at the Surgical Society of Paris on rhinoplasty, *à propos* of some cases by M. Ollier, in which he had attempted the restoration of the nose by a new proceeding. This proceeding was applied to cases in which the remains of the nose were, as M. Ollier expresses it, 'sucked into the nasal fossæ.' It consisted in dissecting a flap from the forehead, comprising both superficial parts and periosteum, and reversing it so as to present its cutaneous surface towards the nasal fossa, where it was expected afterwards to take on the characters of mucous membrane, while the bleeding surface was covered over by a flap dissected off the remains of the collapsed nose. The result was said by M. Ollier to be satisfactory, not only to himself, but to his patients, whom he regarded as still better judges of their own improvement; but some very lively discussion seems to have ensued on this point, some of the surgeons present being by no means pleased with M. Ollier's results, and not at all favourable to any operations of this kind. One of the debaters quoted the case of a patient who, from despair at the disgust produced by his mutilation, had resolved to kill himself, but was weaned from his purpose by the results of the operation. This was met by another speaker, who said that he had another patient, who had thought also of killing himself, and was more than ever confirmed in his resolution when he saw the result of the operation on the other man. This need not be taken seriously, but it seemed agreed on all hands that the effects of such plastic operations are usually only temporary, and that in a year or two the newly formed nose

will most likely wither away. The operation by superimposed flaps seems to have been practised by other surgeons as well as by M. Ollier, and to be regarded as a very efficient proceeding.

WINTER ON DISLOCATION OF THE RADIUS IN CHILDREN.—Dr. Moritz Winter writes a short paper (*Medizinisch-Chirurg. Centralblatt*, May 8, 1874) to call attention to the frequency of the dislocation of the upper end of the radius, whether in front of or behind the external condyle, in youth. The symptoms and appearances of these dislocations when complete are described as in the text-books; but the more original part of Dr. Winter's paper is his statement that he has met with several cases in which the symptoms were so obscure, and the parts so masked by swelling, that no positive diagnosis could be formed, yet in which, suspecting the nature of the injury from the cause (a violent pull on the supinated hand), from the fixing of the arm in the bent and usually also supinated position, and from the way in which the child kept it pressed against the body, so as to avoid the pain of motion, he made attempts at reduction, and the immediate restoration of the head of the bone to its place, with a distinct crack, followed by instantaneous relief of all the symptoms, showed that there was at any rate subluxation if not complete dislocation. He says that experienced mothers and nurses often treat this injury successfully, having observed that pulling the child's hand restores the power of motion; and he urges the necessity, both for the sake of the patient and of the surgeon, of recognising the nature of the injury and treating it in the only proper manner.

OPPIZZI ON LIGATURE OF THE INTERNAL ILIAC ARTERY, FOR FUNGUS HEMATODES OF THE SACRO-ILIAC SYNCHONDROSIS.—Dr. Oppizzi relates (*Gazzetta Medica Italiana Lombardia*) a case in which the internal iliac artery was tied by Professor Porta at Pavia, on July 9, 1873, in the person of a woman forty-five years old, who had a pulsating tumour in the right buttock which had existed for several months, without any known cause. There was no pain in moving the limb, nor any sciatic pain. The pulsation was accompanied by a bruit which is not described further than as a 'souffle very perceptible to the ear.' Compression on the aorta or common iliac stopped the pulsation and bruit at once. There were no tumours elsewhere. No hesitation was experienced in the diagnosis of aneurism. After an ineffectual trial of injections the artery was tied—for the first time at Pavia. Little difficulty was experienced in the operation, which lasted about half-an-hour, and was done without chloroform, the patient submitting very quietly. However, acute peritonitis soon set in, and she died in forty hours.

The tumour was then found to be cancerous and not aneurismal, springing from the innominate bone around the sciatic foramen, and implicating several of the large branches of the gluteal artery.

[This error in diagnosis is one very difficult to avoid. Guthrie's, Moore's, and other cases will at once occur to the remembrance of the surgical reader. The possibility, nay the probability, of such an error furnishes an additional motive for avoiding so dangerous an operation as the ligature of the internal iliac as long as possible.—*Rep.*]

SYPHILOGRAPHY.

WOODMAN ON THE RELATIVE FREQUENCY AND VALUE OF CERTAIN SYMPTOMS OF CONGENITAL SYPHILIS.—Dr. Bathurst Woodman (*Transactions of St. Andrew's Medical Graduates' Association*), gives statistics of the various diseased conditions observed in 200 children of syphilitic parents. In all the cases one parent was ascertained to have suffered severely from the disease, and in all but four or five there was evidence that *both* parents had so suffered. In addition to these 200 cases, Dr. Woodman noted 300 more, in which the symptoms could fairly be attributed to a specific taint; making in all 500 cases of congenital syphilis out of a grand total of about 10,000 patients. The 200 cases in which the history of syphilis in the parents was clear and unmistakable were, however, alone used in preparing the statistics. These showed the symptoms observed in the following proportions: 'Thrush, 66·5 per cent.; snuffles, 54; gummata, 42; specific skin-diseases, 35·5; diseases of anus and genitals, 29·5; glossitis and gingivitis, 22·5; mucous tubercles, 19·5; adenitis, 16; nodes on long bones, 5; enlargements &c. in internal organs, 3; iritis and corneitis 2·5; notched teeth, 2·5.'

Under the term 'thrush' Dr. Woodman includes all forms of stomatitis as well as true parasitic 'muguet,' and enumerates certain features which, he thinks, may be characteristic of a syphilitic variety. With regard to cutaneous gummata and muscular nodes, which he regards as amongst the most certain marks of congenital syphilis, he points out that their occurrence appears to have been overlooked by Diday and other authorities, and that in practice they are constantly mistaken for boils. They may be distinguished from the latter, however, by being less acuminate, flatter, and more rounded on the surface, and often disappear without any destruction of skin. In early stages, the skin is often not reddened or discoloured, and not inflamed. The induration is always more or less annular, and the centre soft and fluctuating; the contents are like thin dirty gum-water, not purulent, and the shreds are fine, without any distinct 'core.' The small number of cases of notched teeth is accounted for by the fact that less than 10 per cent. of the cases had cut the test teeth, the permanent incisors of the upper jaw; and the low percentage of affections of the eye is attributed to the contiguity of the Ophthalmic Hospital at Moorfields, whither such cases would naturally be taken. Mucous tubercles were observed to occur frequently in the mouth—soft palate and tongue—and on the anus in some of the cleanest and best-tended children, and were not therefore due to dirt and neglect, as suggested by Dr. Thomas Ballard. The result affords fresh and independent testimony of the connection between certain groups of symptoms in children and the previous existence of syphilis in the parents, already sufficiently established by Diday, Lancereaux, and others, but which has lately been disputed by Dr. Ballard. These symptoms are pre-

sent only in a certain number of children, and inquiry into their history gives clear and unmistakable evidence of syphilis in the fathers and mothers, generally in both. Now, since the rest of the cases, to the number of many thousands, have been equally exposed to dirt, to the exanthemata, and to other causes which might be supposed to explain the attack, why have they escaped? The coincidence is at least a curious one; and upon this and the success of specific treatment Dr. Woodman is content to rest the case of hereditary syphilis.

[In the list of specific eruptions, the author omits all mention of erythema and tubercular eruptions on the buttocks and maculæ on the face, which are amongst the earliest signs of congenital syphilis, analogous to the roseola and secondary tubercular eruption of the acquired disease.—*Rep.*]

MATERIA MEDICA AND THERAPEUTICS.

THERMES ON ARTICULAR RHEUMATISM TREATED BY PROPYLAMINE AND THE CHLORHYDRATE OF TRIMETHYLAMINE.—Dr. Thermes has published a paper in the *Revue Médicale* of March, 1874, in which he records four cases which have occurred in his own practice where the administration of trimethylamine has yielded excellent results. The first case was that of a man twenty-seven years of age, who was attacked by subacute articular rheumatism on February 13, 1873. His pulse was at 80, and his temperature at 95.5° Fahr.; 75 centigrammes (about 11½ grains) of trimethylamine were administered, and then 1 gramme (15 grains) of propylamine. The next day the improvement was already very perceptible. The pulse and the temperature had fallen. On February 18 the cure was complete, after five days' treatment. In the second case the patient was a man forty years old, who was suffering from his third attack of acute articular rheumatism, which first showed itself on February 15, 1873, the temperature being at 100.4° Fahr., and the pulse from 96 to 100. In the first instance a gramme, then a gramme and a quarter, of propylamine were administered. A marked improvement was noticeable after the 19th; on the 20th the temperature had fallen to 99.7° Fahr. and the pulse to 88. On the 22nd the cure was complete, after eight days' treatment.

The third case was one of multi-articular acute rheumatism. The second attack declared itself on February 18, 1874. The temperature was at 99.5°; the pulse at 84. One gramme of propylamine was given, and the patient was cured by the 25th, and was able to resume work on March 1. The fourth case was also one of general acute articular rheumatism. It was the fifth attack the patient had had. All the previous ones had run an average course of from five to six weeks. The fifth attack declared itself on March 1, 1874. Chlorhydrate of trimethylamine, in doses of 1½ gramme, were administered. Pericarditis supervened on the 4th, with vomitings and diarrhœa, but the treatment was continued. The cure was perfected by the 11th, after ten days' illness and treatment.

GUENEL ON MERCURIAL FRICTIONS IN SERIOUS SYPHILITIC COMPLICATIONS.—In the *Thèses de*

Paris, 1874, no. 145, Dr. Augustin Guenel demonstrates from numerous instances the heroic action of mercurial frictions in the treatment of syphilitic complications; more especially when they affect the cerebro-spinal axis. He shows that this method, which has the advantage of not distressing the digestive tube, acts as well against secondary accidents as against tertiary, and that it often succeeds where internal medication has failed.

SIMBAT ON THE USE OF CHLORIDE OF ZINC IN THE TREATMENT OF FISTULA.—In a paper published in the *Thèses de Paris*, 1874, no. 73, and based on cases for the most part observed in M. Gaujot's service at the Val-de-Grace, Dr. Simbat shows the good effects which may be obtained by the use of Canquoin's paste in the treatment of fistula, and particularly in the use of anal and even urinary fistula. The chloride of zinc is employed with advantage in the treatment of fistula, in consequence of the granulating power it imparts to their walls; by reason of the facility with which it is applied; also in consequence of the absence of the accidents which might accompany wounds from cutting instruments; and, lastly, because it is more likely to prevent recurrence of the evil than other methods of operation.

ORÉ ON INTRAVENOUS INJECTIONS OF CHLORAL. M. Oré, in a communication to the Paris Academy of Sciences, upon intravenous injections of chloral, arrives at the following conclusions. To obtain complete anæsthesia, the solution should be of one-third strength. Injection should be effected always by the process of direct puncture, without denudation of the vein. The surgeon should perform the operation slowly, so that he may sound the predispositions of the patient. When the patient indicates that a sleepy feeling is attained, anæsthesia is also imminent. From the time that sleep is produced, injection should be discontinued; in a few minutes such a state of anæsthesia will evince itself as chloroform could never produce. The operation concluded, immobility may be removed by application of the electric current. From the commencement of the operation the surgeon should have in readiness an electrical apparatus. Anæsthesia produced by intravenous injection of chloral is applicable to all surgical operations, especially to those of long duration, resections, ovariectomies, etc.

CROLAS ON THE OBTAINING OF CHEMICALLY PURE IRON FOR MEDICINAL PURPOSES.—It is well known that commercial iron contains sulphur, phosphorus, and arsenic; that hydrochloric acid contains arsenic and sulphuric acid; carbonate of soda and water both contain sulphates. These substances, generally employed in the reduction of iron, it is difficult to obtain chemically pure. To use them otherwise results in the production of sulphuretted, phosphoretted, or arseniuretted hydrogen, forming during reduction of the iron, sulphides, etc., as impurities. It therefore becomes necessary to purify the hydrogen, and to deprive the oxide and the water employed of the sulphates they contain. In order to arrive at the first requisite, M. Crolas employs Dumas and Boussingault's process, which applied with care gives perfectly pure hydrogen. The protochloride of iron may be deprived of sulphates by chloride of barium, crystallising to separate the chloride of barium there may be in excess, dissolving in distilled water, and precipitating by ammonia

(which M. Crolas finds to be free from sulphates). By this means washing the oxide is avoided, for it suffices, to remove the hydrochlorate of ammonia formed and retained by the precipitate, to raise it to a nearly red heat. To avoid the formation of oxide, there is arranged between the hydrogen wash-bottles and the reduction retorts an iron tube, which being heated and traversed by the hydrogen thoroughly dries the gas. Iron prepared by this process is chemically pure, and never gives rise to formation of sulphuretted hydrogen while in the stomach.

OBSTETRICS AND GYNÆCOLOGY.

MARTINEAU ON THE USE OF CHLORAL IN PREMATURE CONFINEMENTS.—At the sitting of the Therapeutical Society of Paris, held on April 8 (*Bulletin Général de Thérapeutique*, April 30), M. Martineau, after having reminded the meeting of the interesting communication made to it by M. Burdon on the excellent effects obtained from the employment of chloral during labour-pains and delivery, communicated the following two cases. Last year at the Hôtel Dieu, a patient in the seventh month of pregnancy was admitted with an attack of intermittent fever. Under the influence either of the sulphate of quinine or of the fever, the colic pains, the usual precursors of delivery, came on. The use of Sydenham's laudanum as an injection had no effect. M. Martineau then prescribed some injections of chloral, and had the satisfaction of seeing the pains and the uterine contractions cease. The pregnancy continued its normal course. (M. Martineau has lately seen an analogous fact, in which the action of chloral was most strongly manifested, in the instance of a young woman nineteen years old, half-way through the fifth month of her pregnancy.) On March 15, having been exposed to the influence of cold, this lady had a violent attack of shivering; and on the 16th M. Martineau ascertained the existence of pleuropneumonia on the right side, with fresh fever and intense oppression. Twenty cupping-glasses were applied on the side affected, so as to remove 200 grammes (about 7 ounces) of blood, and a draught containing antimony and ipecacuanha was administered. The condition remained the same on the 17th, and the same treatment (cupping and draught) was continued, with the addition of a blister on the affected side. In the course of the night, between the 17th and 18th March, at one o'clock in the morning, the patient was taken with uterine and lumbar colic, and M. Martineau being called in, ascertained that premature delivery was threatening. The pains were very violent, succeeding each other with great rapidity, and a sanguinolent discharge escaped from the vulva. He prescribed an injection composed of one gramme (15 grains) of hydrate of chloral in 125 grammes of water. At 8 A.M. the pains were less frequent, less intense; the bloody discharge persisted, and a second injection of chloral according to the same formula was given. At midday there were only some occasional lumbar

pains; the bloody discharge had almost ceased. A third injection was given, and at 6 P.M. the pains had completely ceased; there was no discharge whatsoever. A fourth injection was administered. The patient had a quiet night on the 18th. The pneumonia in the upper part of the lung was in process of resolution. There were no special symptoms about the uterus. The premature delivery was arrested, but as a matter of precaution a fifth injection was administered. The pleuropneumonia was cured at the end of nine days. Premature delivery did not take place, and after some days the patient felt the movements of the child.

M. Mialhe saw in M. Martineau's facts the confirmation of the hypothesis which declares that chloral has no other action than belongs to chloroform. M. Gubler did not agree with this. Chloral, he said, like chloroform, quiets pain: they are both calmants, but their action differs. Besides, the blood in presence of the chloral could only induce the production of 25 to 30 centigrammes of chloroform in the hour, and this would not explain the very strong action of the chloral.

M. Limousin was inclined to ask himself if the alkalinity of faecal matters did not induce the production of chloroform when chloral is administered as an injection.

M. Gubler answered to this that he had ascertained that faecal matters were not uniformly alkaline—sometimes they were acid, sometimes neutral.

GOSCHLER ON PELVIC CELLULITIS.—Of all authors who have written on this affection, Dr. Goschler (*Allgemeine Wiener Mediz. Zeitung*, Feb. 3, 1874, and following numbers) gives the preference to the views of Kiwisch, who considered pelvic cellulitis a metastatic inflammation of the cellular tissue, occurring either in the lower pelvic space in the neighbourhood of the uterus, or in the aponeurotic expansion of the internal iliacus muscle, or in the sheath of the psoas. Similar deposits are seen also in the region of the anus, the labia, and the anterior abdominal wall.

Kiwisch regarded abscesses in either the anterior or the posterior pouch of Douglas as exudation-cysts, the results of a previous peritonitis. Respecting its etiology, amongst the many complications such as abortion, injections into the uterus passing into the peritoneal sac, &c. Dr. Goschler believes it from his own experience to be generally the result of a difficult labour, where there has been some disproportion between the pelvis and the child's head, causing delay in the second stage. Two or three days after delivery, through peeling off of the vaginal mucous membrane, ulcerations and abscesses arise. By many gynaecologists these are attributed to endometritis. Grissol considered that they arose through weaning of the child; and West regards his theory as highly probable.

Is there a milk-metastasis? There is indeed a sympathetic connection between the uterus and breasts; but between the former and the connective tissue, one has never yet been proved. In Dr. Goschler's estimation, pelvic cellulitis is solely the result of mechanical pressure. Inflammation of the cellular tissue is of three kinds:—*a.* an albuminous or slightly fibrinous exudation, which is rapidly reabsorbed, leaving no traces of any kind; *b.* a fibrinous exudation which does not resolve, but remains in the form of hard nodular masses; *c.* the last, and by far

the most important, goes on to suppuration, which may be either diffused or circumscribed, leading to thrombosis of the pelvic veins, and, when the iliac veins are affected, to phlegmasia alba dolens.

The diffused abscesses may either extend to the periosteum, separating it from the bones and producing caries and superficial necrosis of the pelvic bones, or may give rise to suppuration of the inter-articular cartilages of the symphysis pubis, and of the lumbo-sacral and the sacro-iliac articulations.

In pelvic cellulitis, the functional disturbances relate principally to the uterus, the bladder, and the rectum, rarely to the intestinal tract. There is scarcely ever any sickness or diarrhoea. The fever is not so intense as in pelvic peritonitis, and there is a remission in three or four days. In acute pelvic peritonitis, the signs of acute peritonitis are always present; in the subacute the same, only milder in type and localised.

In parametritis there is no meteorism, and the tenderness in the hypogastric region is at first only discoverable on deep pressure. Vesical and rectal troubles do not show themselves for some days, until after a considerable amount of exudation has taken place, producing dysuria or obstinate constipation. These two latter affections are very characteristic of the disease. Should the exudation be so considerable as to press on the sciatic plexus of nerves, paraplegia, or occasionally hemiplegia, may result. The patients are incapable of moving their extremities in the slightest, turning in bed, or sitting up, until the exudation has been reabsorbed. No swellings are discoverable externally, except when the broad ligaments are affected. Displacement and fixation of the uterus are the chief diagnostic points in subacute pelvic cellulitis.

The symptom of the chronic subacute form which first attracts attention is a tumour felt through the abdominal walls in the region of the broad ligament, displacing the uterus, but not fixing it. It may occasionally happen that its movements are somewhat restricted, but it is never completely immovable, and the mass is not always to be felt *per vaginam*. If these symptoms be compared with those attending pelvic peritonitis, we find, coupled with displacement and fixation of the uterus, an expanded hardness of the floor of the pelvis, without any vaginal tumour. In purulent peritonitis there is a soft and less resisting tumour, which is, however, quite exceptional, as Bernutz, by his numerous examples, has shown.

Dysmenorrhœa, amenorrhœa, menorrhagia, vesical and rectal troubles, with a sensation of weight in the pelvis, and pains in the hip, down the thighs and buttocks, are the ailments which bring the patients to the physicians for relief in both forms of the disease—pelvic peritonitis or cellulitis.

In order to treat the cases properly, Dr. Goschler maintains that an exact diagnosis must be made, and great care should be taken to eliminate all those affections that are liable to be mistaken for either; such as retrouterine hæmatocele, fibrous tumours, prolapsed ovary, displacements of the uterus, fecal accumulation in the upper third of the rectum, which latter may be easily mistaken, especially when opium has been given to relieve pain.

The sequelæ of pelvic cellulitis are various—fixing of the uterus, causing abortions, versions, flexions; and, should there have been some peritoneal exudation liable to become organised, they are rendered permanent. Flexions and versions may produce,

according to their forms and gradations, amenorrhœa, dysmenorrhœa, menorrhagia, metrorrhagia, uterine catarrh, and sterility.

Retroflexions and retroversions may entail diseases of the rectum, piles, constipation, &c.; antelexions and anteversions, affections of the bladder, dysuria, strangury, cystitis, calculi, &c.

Respecting its prognosis, the disease is rarely fatal. In parametritis, absorption of the effused lymph is common; in perimetritis, rare, and the affection is more permanent.

The treatment depends on the form and condition with which one has to deal. Rest, warm injections *per vaginam* and rectum, and hot fomentation, are amongst the chief remedies. If there be indications of matter having formed, it should, if possible, be encouraged to break above Poupert's ligament; experience has shown that the opening of abscesses by the rectum and vagina may be attended with serious danger.

The author relates two typical cases bearing on this plan of treatment, and the means adopted for their diagnosis: they terminated most successfully.

DEPAUL ON THE DECAPITATION OF THE FÆTUS IN UTERO.—M. Depaul (*Archives de Tocologie*, June, 1874) publishes two cases. The first operation was performed on a multipara, who was brought into the hospital in a very exhausted state, with the shoulder of the child presenting and the left arm protruding from the vulva. Ergot had been given. Failing to turn the child, through the extreme contraction of the uterus, he at once proceeded to decapitate the fœtus, which was dead, with M. Dubois's long scissors. The operation was comparatively easy. The trunk was then extracted by means of the left arm, and the head by two fingers being placed in the mouth. The woman did well. The second was a case of twins; the first child was born three days before the waters of the second broke. The labour making no advance, the woman was brought into the hospital. M. Depaul endeavoured to turn the child, whose right arm, in a putrid state, was lying in the vagina. Not succeeding, through the tetanic spasm of the uterus, he divided the neck as in the previous case, which was not quite so readily performed, on account of the height of the fœtus in the pelvis. The trunk was brought down, but he failed to extract the head. He twice attempted to diminish the head by perforation, but on account of its soft and putrid condition it could not be fixed. After numerous trials he desisted for some hours, when, having fixed the head in the pelvis by means of assistance, he applied the ordinary forceps and delivered it. The woman died. The necropsy revealed local peritonitis of the left pelvic cavity. The inner surface of the uterus was covered with a dark offensive substance. The sinuses were open and healthy, with the exception of the circular sinus of the neck, which was filled with thick pus. The putrescent gas had escaped into the cellular tissue of the broad ligaments, and through the Fallopian tubes into the peritoneal cavity.

VEIT ON CLOSURE OF THE UTERUS BY SUTURES AFTER CÆSAREAN SECTION.—A paper on this subject by Dr. Veit, of Bonn, was read before the Berlin Obstetrical Society on October 28, 1873. He disapproves of Martin's method of stitching the uterus to the abdominal walls, as tending to produce lacer-

ation of both wounds. He considers it most desirable that the uterine wound should be closed. Not only may Lister's catgut sutures be left with impunity in the peritoneal cavity, but also, the knot becoming undone, the stitch falls into the cavity of the uterus to be afterwards discharged with the secretions. Under these circumstances, Dr. Veit describes two cases in which he operated. In the first, he closed the incision in the uterus by means of eight catgut sutures, and the abdominal wound with ten silk ones. The patient recovered without a single bad symptom. In the second instance, seven deep and two superficial catgut sutures were used, the abdominal incision being closed with the same material. After many relapses the case ultimately did very well. Dr. Martin related, at the same meeting, the case of a patient convalescing most favourably, in which he had used Veit's plan.

DUFOUR ON PREGNANCY WITH PERSISTENT HYMEN.—M. Dufour (*Archives de Tocologie*, June, 1874) was consulted by a lady for some abdominal enlargement. On feeling the tumour, the movements of a child were apparent. On proceeding to make a vaginal examination, his finger was prevented from entering the passage by a complete circular band, which ocular demonstration proved to be the hymen. In leucorrhœa the parts sometimes become much relaxed, and rendered thereby very dilatable, so that under certain circumstances the act of coitus may be completed without any rupture of the hymen. In this case the patient said that she had never suffered from the 'whites,' and this was substantiated by the condition found.

DE LA HARPE AND MÖHRLÉN ON VESICULAR RASH OF THE UTERUS.—Dr. de la Harpe and Dr. Möhrlén (*Archives de Tocologie*, June, 1874) report a case where the patient thought herself about four-and-a-half months pregnant. During the latter two-and-a-half months, anomalous symptoms presented themselves—slight uterine hæmorrhage, which was sometimes very fluid, at others clotty. At the end of the fourth month she became anasarcous, and had albuminuria, coupled with hydrothorax, bronchitis, and orthopnoea. Uterine contractions were felt on placing the cold hand on the abdomen; *per vaginam*, the cervix was found softened and swollen, about an inch long. A vesicular mole was suspected, and ergot was given; shortly afterwards a very large hydatid mole was expelled. The chest and anasarcous conditions rapidly disappeared. M. Möhrlén had observed a precisely similar case a short time previously. M. de la Harpe instituted inquiries to see whether this anasarcous condition was an usual concomitant, and whether it could be in any way regarded as pathognomonic of the affection, but failed in doing so.

CHARPENTIER ON DIFFICULT REMOVAL OF THE HEAD IN A CASE OF BREECH PRESENTATION.—Dr. Charpentier (*Archives de Tocologie*, June, 1874) relates a case occurring in a primipara, where, after having extracted the trunk and arms, he failed in delivering the head until after a lapse of nearly twenty minutes. The cord had ceased to pulsate for some minutes. The perinæum was slightly ruptured. It was not without difficulty that the child was resuscitated. Dr. Charpentier believes that life was kept in the child through the mouth being close to

the external maternal parts, and thereby being enabled to inspire air into the lungs sufficient to sustain life and allow reanimation after birth. In all similar cases, where the head is retained, he strongly advises the immediate application of the forceps.

HUBER ON PARTUS SEROTINUS AND ON ACEPHALIA.—Dr. Huber (*Ertzliches Intelligenzblatt*, March 25, 1874) relates a case where he was called to attend a well-formed, well-nourished woman, mother of six children, who had exceeded her date of reckoning by nearly four weeks. The face was presenting. No progress being made, instruments were applied, and the head delivered. The fœtus was found to be acephalic. It was not until after several hours of arduous endeavours that the body could be brought forth. The child weighed eight pounds (German). The perinæum was much torn. The woman did well. He remarks that Schröder and Hohl, as well as Halle, noticed that in cases of acephalia the shoulders and body were excessive in size, retarding delivery; also that Isidore Geoffroy St. Hilaire observed that, when women exceeded the ordinary term of gestation, the fœtus was not only above the average size and strength, but also that in cases of acephalia it was of inordinate size, and the labours were tedious and retarded.

A second case occurred in the author's practice where the foot presented, and similar difficulty was experienced in delivering the body.

Respecting the diagnosis *in utero*, Cazeaux calls attention to the remarkably convulsed and inordinate movements of the fœtus when the stump-like nodule of brain is irritated by digital examination. This of itself should excite suspicion, and lead to a correct diagnosis.

KAUFMANN ON EXPULSION OF AN UTERINE FIBROID.—At the meeting of the Berlin Gynecological Society, on December 9 (*Berliner Klinische Wochenschrift*, April 20) Herr Kaufmann reported a case of spontaneous expulsion of a large fibroid of the uterus in a woman aged forty who had borne two children. Two other cases were related by members present; in all these cases the recovery was most rapid. W. C. GRIGG, M.D.

CUTTER ON THE TREATMENT OF SORE NIPPLES. Dr. Ephraim Cutter, of Woburn, Massachusetts, suggests (*New York Medical Record*) the following treatment for sore nipples.

The problem is to have the nipple, during the intervals of suckling, protected from the pressure of the clothes and freely open to the circulation of dry air. To accomplish this disks of cork, about 2½ inches in diameter and 1½ in thickness, are selected. A central opening is made, and then enlarged by filing with a common rat-tailed file until the opening on one side is within half an inch of the edge, and that on the opposite side about one inch in diameter. The surfaces are smoothed and rounded by sand-paper. Thus there is a conical excavation within the cork which will cover the nipple, keep off the clothes, and allow ventilation. The lightness of the cork, its being a non-conductor of heat, and its facility of manipulation, entitle it to a first place for this purpose. At first sight it might appear that the cork would absorb the secretions, so as to become offensive, but Dr. Cutter has not found it so. It is easily cleansed by pouring on boiling water.

With this device remedies may be employed. He

has found an ointment of a grain of sulphate of morphia to a drachm of lard an excellent application after suckling, to be removed if not absorbed before suckling.

OTOLOGY.

POORTEN ON THE CONDITION OF THE EUSTACHIAN TUBE DURING LIFE.—In the *Monatsschrift für Ohrenheilkunde*, for February, 1874, W. Poorten describes an experiment which he made towards the settlement of the discussion as to whether the Eustachian tube is open or shut during life. He made an opening at the curvature of the usual silver catheter, which opening he placed opposite the mouth of the larynx, and through this silver catheter he passed one of Weber-Liel's tympanic catheters, with a perforation in the latter which he could at will apply to the opening in the silver catheter. With the perforations opposite the mouth of the larynx, the tuning-fork on the cranium gave equal sounds in both ears. On closing, by means of a bougie, the tympanic catheter up to, but not including, the opening in the silver catheter, the patient complained that when he spoke he felt as if in a barrel, but on removing the bougie the patient said this feeling passed off, and the sound seemed distributed. He found that if the tympanic catheter did not pass the isthmus of the Eustachian tube the feeling described was not present, but reappeared the moment the isthmus was passed. From this he concludes that from the ostium tympanicum to the isthmus is an open canal.

BEZOLD ON PERFORATION OF THE MASTOID PROCESS.—Dr. Bezold, in concluding a paper on perforation of the mastoid process in the *Monatsschrift für Ohrenheilkunde*, for February, 1874, considers the point hitherto selected for operation as too far back, and rendering the operator liable to wound the transverse sinus, an accident which, however, does not necessarily prove fatal. From measurements made on a hundred temporal bones he concludes, that a perforation commenced 11 millimètres behind the posterior wall of the external meatus will avoid the transverse sinus, and give the easiest entrance to the antrum mastoideum. The operation he proposes is as follows. The incision through the skin should be begun somewhat over the position where the linea temporalis cuts the attachment of the auricle, and should run in the curved attachment to the beginning of the under third of the auricle. The attachment of the auricle with the periosteum underneath it is now loosened from the underlying bone, and the perforation is made so that its upper boundary is half a centimètre under the linea temporalis. As in seven per cent. of the bones examined the isthmus between the transverse sinus and the meatus was found to be only 7 millimètres across, it is necessary, in order to avoid the sinus, to pass through this isthmus within 7 millimètres of the posterior wall of the meatus. The bone at the part where the opening

is proposed to be begun forms a moderately sharp angle with the long axis of the meatus, which makes it somewhat difficult to start the perforation; but this is compensated for by the bone being softer here than more posteriorly. By keeping along the posterior and upper wall of the meatus, the instrument will enter the antrum in from 10 to 12 millimètres. It is not advisable to go beyond this distance, as at from 18 to 20 millimètres the horizontal semicircular canal and the second bending of the Fallopiian canal are met with. The instrument which Dr. Bezold prefers is a hand-gauge from 3 to 5 millimètres broad.

In cases of asymmetry by an abnormally developed fossa sigmoidea, or marked cranial deformity, or where the mastoid process is small, and so gives a small amount of room to work upon, he would advise avoidance of the operation till we have further experience.

BING ON PERFORATION OF THE MEMBRANA TYMPANI.—Dr. Albert Bing, Assistant in the Vienna University Clinique for ear-diseases, has written an article in no. 35 of the *Allgemeine Wiener Med. Zeitung* for 1873, on perforation of the membrana tympani. He thinks that Wilde's explanation of the cause of the perforation being most frequently at the lower anterior quadrant, viz., the concussion of the air from the Eustachian tube on that point, is not sufficient, and he denies that the air comes against that part more than against any other. He considers that the doubly oblique position of the membrane, and the pressure of the mass and weight of the accumulated exudation, which, from the position of the quadrant, outwards and under, and the trifling breadth of the base of the tympanum in this region, gives it a ground pressure in addition to the other actions common to other parts, are the true causes.

The reason of the giving way in the intermediary portion between the manubrium and the cartilaginous ring has been hitherto ascribed to the elastic elements of the substantia propria being fewer here; but Bing thinks that the fact that this spot of the membrana tympani is furthest removed from its attachment, and that the opposition force of an extended membrane against a pressure force decreases with the greatness of the removal from its point of attachment, ought to be taken into consideration.

W. LAIDLAW PURVES, M.D.

EPIDEMIOLOGY.

HAVILAND ON THE COMMUNICABILITY OF TYPHOID FEVER.—Mr. Haviland, the Medical Officer of Health for the Northamptonshire district, in a report to the Sanitary Authority, relates a case in which enteric fever was in all probability communicated to a whole family. In the month of October last the wife of a tradesman in Wellingborough, Northamptonshire, contracted enteric fever of which she was ill for several weeks; and during which time she was attended by a servant, a girl fourteen years of age. In the beginning of November this girl became ill, whereupon her master sent her to her home in Stanwick, a place some miles from Wellingborough. On reaching her home, having walked about three miles, and having, besides, travelled some distance by rail, she fainted from exhaustion. For six weeks she lay sick of the fever, which attacked in turn her father, mother, brothers, and sisters.

[This is fortunately an unusual occurrence; in the majority of such instances the fever having been typhus, not enteric. At the same time it cannot be reasonably denied that enteric fever is a communicable disease (and that perhaps more frequently than is imagined) in the way Mr. Haviland has pointed out; and the present reporter has evidence which he regards as conclusive on the matter. That the diagnosis of the fever was correct is supported by the long duration of the girl's illness, which must have been at least about twelve weeks, for we are told that she passed six in bed, and another six would certainly be required for the complete recovery of strength; this is just about double the time which would be necessary in typhus fever, especially in a patient at the early, and for typhus most favourable age, of fourteen. Whether ignorance, thoughtlessness, or absolute inhumanity was the cause of all the misery of which Mr. Haviland informs us, does not appear; but we cannot help saying that some blame attaches to whoever usurps medical functions of any kind, and we think something more than blame attaches to whoever ventures to decide a matter so important as the removal of a sick person from one locality to another, without competent medical advice.—*Rep.*]

GAYTON ON SMALL-POX AND VACCINATION.—In a report to the Committee of the Homerton Small-Pox Hospital, Mr. Gayton, the Medical Superintendent, states that from February 1, 1873, to January 31, 1874, he had admitted 110 cases of small-pox, of which 20 died. Of the whole number 69 are classified as discrete, all of which recovered; 9 as semi-confluents, of which 1 died; 25 as confluent, of which 12 died; 3 as hæmorrhagic, and 4 as malignant, all of which died. Seventy-eight of the cases had been somehow vaccinated, and of these 11 died or 14.1 per cent.; 32 had not been vaccinated at all, and of these 9 died, or 28.1 per cent. As one more proof of the great value of re-vaccination, Mr. Gayton mentions that of 133 persons employed in the service of the hospital since its opening on February 1, 1871, not one had been attacked by small-pox. ALEX. COLLIE, M.D.

MISCELLANY.

HONOURS FOR MEDICAL SERVICE DURING EPIDEMICS. His Majesty the Emperor of Austria has lately conferred the honour of the Iron and Golden Crowns on a number of medical practitioners, in recognition of their services during the epidemics of cholera and small-pox in Austria and Hungary.

INTEMPERANCE AND CRIME.—From a work entitled *The Dangerous Classes of New York*, by C. L. Brace, we learn that nearly two-thirds of the crimes committed in New York spring from habits of drunkenness. Out of 49,423 criminals who were received into the prisons of that city in 1870, 30,507 were habitual drunkards, and a large part of the 19,000 others were in the habit of getting intoxicated occasionally. In the penitentiary at Albany also, there were 1,093 prisoners during the same year, of whom 893 owned to being drunkards. Amongst the street Arabs of New York, 90 per cent. were ascertained to be the children of known drunkards.

M. OLLIER, of Lyons, has been elected a corresponding member of the French Academy of Sciences.

PREVENTIVE MEDICINE.—An international sanitary conference is now sitting at Vienna, presided over by the Baron von Gager, and attended by representatives of the medical profession from all the countries of Europe. Amongst the measures of preventive medicine submitted to the united medical wisdom of the European continent are, what quarantine restrictions are in harmony with the accumulated experience and the scientific knowledge of the present day, and the institution of an international commission for the study of epidemics. It will be the duty of this commission to send special commissioners to all localities where epidemics show themselves, and to officially report upon the causes of the outbreak and its cessation.

AN UNWELCOME VISITOR.—We regret to state that small-pox, in a most virulent and fatal form, has been prevailing in Birmingham, the great central town of England, for the last seven or eight months, during which time, up to the week ending May 30, no fewer than 289 deaths have been recorded. There is great reason to fear that the disease is gradually radiating from its original centre into the counties of Northampton, Leicester, Rutland, and Bucks, and under these circumstances it is evident that the most stringent precautions will be necessary. The vaccination officers must carry out fully all the powers with which they are armed by the Compulsory Vaccination Act, and insist on all parents and guardians having the children under their care properly vaccinated. Where prejudice against vaccination exists, as is but too frequently the case, much good might be effected, and the public health in some measure protected, if ministers of religion, schoolmasters and mistresses, and district-visitors, were to make a house to house visitation in their own districts, and use argument to induce those who are not vaccinated, or their natural protectors, to resort to this valuable prophylactic against one of the most severe scourges to which mankind is amenable.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 3d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S.W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JUNE 24, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

THE TREATMENT OF CONSUMPTION.*

(Gleaned from Clinical Lectures at the Hospitals of New York.)

The great controlling idea which should govern the medical adviser in the management of this class of cases is the adoption of such measures as will secure the best possible condition of nutrition.

As far as the lungs are concerned, they should be made of secondary consideration. Special symptoms and local manifestations are not to be regarded as the great questions at issue. Not everything that is done is to be done with the view of checking a diarrhoea, improving the appetite, arresting night-sweats, quieting the cough, etc.

The Question of Climate in Phthisis.—First, a proper atmosphere should be given the patient to live in. An air should be obtained, if possible, of such a nature that it can be breathed for the greater part of the twenty-four hours. Second, give the patient the benefit of sunlight. Third, avoid an atmosphere loaded with dust. Fourth, exercise without producing fatigue.

The climate should be selected, if change of climate is to be made, in which the patient can be the most comfortable for the greater part of the twenty-four hours, for that is the climate which is to prove the most beneficial. The temperature and locality are in general secondary considerations. As a rule, a low and damp location is injurious.

If the patient cannot be exposed to out-door air without feeling chilled, and is necessitated to sit by a fire when he returns, for the sake of again feeling comfortable, it is much better for him to remain in the house and make an atmosphere for himself by artificial means, and then take regularly such light gymnastic exercise as will keep the body in the best possible condition. If change of location is to be made, the patient should be sent to some place where he will have a good time. Never send a patient where he will be surrounded with depressing and unhappy influences. Never send a patient in the advanced stage of consumption away from home, unless he be so situated that he can take his home and all its comforts with him. Never send a person with consumption to the sea-shore, unless the experience of the individual have proved such an atmosphere beneficial. In general it does harm. Some favour long sea-voyages in the earliest stages. Especially avoid the habit of sending every patient to the same place. In case the patient enjoys hunting and fishing, if he can be sent to a locality where he can have his favourite sports, it will prove an additional item in his favour. The man who is fond of these sports is much more likely to get well of his

phthisis. If these external general conditions can be controlled, no great amount of anxiety, as a rule, need be manifested with regard to the cough. It is the cough generally that most attracts the attention of the patient. The great object to be held in view is to raise the health of the patient to a level above that in which phthisis progresses. The power of drugs to accomplish this is very doubtful. Alcohol is of doubtful efficacy. If used at all, it should be used with the view of assisting digestion; and the article selected should be that most agreeable to the stomach. Air free from moisture and dust, food and exercise, are the things to be relied upon in the general treatment of this disease.

There are certain effects of the disease which the physician will be called upon to counteract, and for the relief of these he may be obliged to resort to some therapeutical measures. It is to these conditions and measures that attention is now especially directed.

The Cough of Phthisis.—Phthisis occasionally occurs without cough, but these cases are almost always complicated ones. The insane may go through the entire course of phthisis without cough. For the relief of the cough of consumption, an almost endless retinue of cough-mixtures have been formulated. Most of them contain opium. The effect of the opium is simply to blunt the sensibility, and permit the material to accumulate which is to be expectorated. An additional result is, that opium is almost sure to injure the patient's digestion. If it become necessary to do anything for the relief of cough, there is nothing more serviceable than morphine. While administering it do as little as possible in the way of producing another evil, by the arrest of one already existing. What are commonly known as cough-mixtures are ignored. When remedies for relieving the cough must be used, use, by preference, those which have the most powerful quieting influence without disturbing the stomach.

Distress after Eating and Diarrhoea is a very common occurrence. There are two conditions upon which diarrhoea and distress after eating depend. They may depend upon a hyperæmic condition of the gastro-intestinal mucous membrane, consequent upon irritation produced by indigestible food, or diarrhoea may be caused by ulceration of the intestines. When diarrhoea or distress after eating occurs in the earlier stages of the disease, it is most probably due to hyperæsthetic condition of the mucous membrane, and a hyperæmic condition, of which the diarrhoea is but an effort to relieve the engorged mucous membrane. Simply arresting the discharges from the bowels is not well. If several watery discharges be produced without pain, the engorgement will be relieved; and then opium and astringents may be used with benefit if necessary. As a rule, opiates and astringents are to be resorted to only as secondary measures.

A very efficient prescription to be administered under the circumstances is:—

R. Sulphate of magnesia,
Camphorated tincture of opium . . . aa ʒj
Water Oj

A wineglassful is to be taken every two or three hours, until two or three free watery stools are produced. To prevent recurrence, the diet must be regulated. When the bowels are irritable, beef-tea is apt to purge. Milk, farinaceous food, yolks of fresh eggs beaten up with wine and sugar, may be

* *New York Medical Record*, June 1, 1874.

given. If these do not agree with the patient, raw beef scraped fine may be tried; or it may be just heated through, and then scraped fine and seasoned with pepper and salt; and in some hospitals vinegar is also allowed.

An exceedingly serviceable remedy to be regularly administered in these cases of disturbed digestion, irritable mucous membrane and diarrhoea, is lacto-phosphate of lime. The article must be fresh, and must be kept in a cool place. Unless these precautions are taken, the remedy itself will prove purgative.

Pepsin combined with muriatic acid is an excellent assistant to digestion under these circumstances; also fatty meat, thoroughly boiled pork, fresh butter; perhaps cod-liver oil.

Thoroughly boiled pork is most excellent for children who suffer from summer-complaint. The diarrhoea of phthisis may occur from simple thickening of the mucous membrane of the small intestines. When the diarrhoea depends upon ulcerations in the intestines, the regulation of the diet is an exceedingly troublesome undertaking. Resort should be had to those articles of diet which will give as little trouble as possible in the latter stages of the digestive process. If the ulceration be in the small intestines, cod-liver oil and the hypophosphites may be of great service. If the ulceration be in the large intestines, little more than temporary relief can be expected. The presence of blood in the discharges is regarded as evidence of ulceration in the intestines. The seat of the pain, tenesmus, etc., is generally sufficient to distinguish ulceration of the large intestines from ulceration of the small intestines.

The most relief to be obtained from drugs is when the diarrhoea depends upon ulceration of the small intestines. The treatment adopted for the diarrhoea which depends upon a condition of hyperæmia is not of much service in this condition.

Among drugs, subcarbonate of bismuth is regarded as one of the best remedies that can be employed. It may be given in doses as high as a drachm three times a day.

R. Bismuthi subnitratiss . . . 3j
Morphiæ sulphatis . . . gr. j
M. Divide in pulvres xij.
One every four, six, or eight hours, occasionally.

Sometimes relief will be derived from the use of mineral waters. Water from the Rock Ridge lime-spring of Virginia is the best that can be employed. The water contains lime and iron, and is astringent and tonic. Of this from two to four ounces may be taken every three to six hours. It can be taken clear or with other water.

In the latter stages of the diarrhoea of phthisis, especially when the large intestines are the seat of ulcerations, opium is the chief remedy to be relied upon. When given to relieve pain, hypodermically or by suppositories, it is much less liable to disturb the stomach. Suppositories made of gum opium alone are much more efficient than when the opium is compounded with other substances.

Salicine, in ten-grain doses, three times a day, has something of a reputation in the treatment of diarrhoea of phthisis. The remedy may be given in divided doses, and administered more frequently if desirable.

Vomiting after Meals is quite common, and when present is apt to be troublesome. A wineglass of champagne, taken during meals, will sometimes arrest it at once.

Dilute hydrocyanic acid, in doses from 3 minims, gradually increased to 7 minims, administered just before each meal, is another remedy. The condition is ordinarily one of irritability, and if the acid can be carried so as to produce quite marked sedative effects, it may be of great service.

Raw Beef scraped or cut fine and seasoned.—Let the patient take teaspoonful or half-teaspoonful doses every hour or two, or oftener, and subsist upon this alone for a few days. The effect is very beneficial in many cases. Another method of preparing it is to lay a piece of beef upon live coals, immediately turn it, and immediately remove it. This cooks the meat the least possible amount, and yet gives it a flavour which, to many patients, is much more agreeable than when perfectly raw. It is then cut in small pieces, seasoned, placed by the bedside of the patient, and every now and then a piece is taken, chewed, and swallowed. This is a most excellent means for overcoming the vomiting which is sometimes present in chronic Bright's disease.

Hæmoptysis to the patients is an alarming symptom. As a general rule, they do not die of hæmoptysis. In fact they do better, and are rather more likely to recover or have an arrest of the disease, when hæmorrhage occurs. Those cases which do recover almost invariably have a hæmorrhage before recovery takes place. The moral effect produced upon the patient when such encouraging expressions are given him is sometimes wonderful. It is in the early stages that hæmorrhage may be beneficial; but from the middle to the latter part of the disease the result may be different. If the patient have bled a little, place him in bed and keep him perfectly quiet. If he belong to that class who can take opium without producing unpleasant secondary effects, a moderate dose will diminish the moral effect which the hæmorrhage has produced, and will also diminish irritability. Salt may have some effect, and certainly it can do no harm. It may be taken in small spoonful doses, followed by water. It sometimes, without doubt, does good, for it ordinarily purges when administered in this manner, and it is a remedy of which the patient will not be afraid. In those cases where the patient occasionally spits up a teaspoonful or so of blood, do not resort to inhalations of nitrate of silver or persulphate of iron.

Ergot is employed as a hæmostatic. Hypodermic injections of ergotine may be given in doses of one grain to one grain and a half. The fluid extract may be used in doses varying from 20 minims to a drachm occasionally. If ergot given by the mouth does not produce vomiting, it is apparently of some service. One of the following pills may be given every four hours. R. Pulveris secalis exsiccati, Acidi gallici, ãâ ʒss.; Extracti gentianæ, q. s. M. Divide in pil. x. *Quinia* may be given in five-grain doses every hour until the pulse and temperature are brought down.

One of the most powerful hæmostatics in the *materia medica* is turpentine. It is an exceedingly beneficial remedy in the treatment of *all* internal hæmorrhages.

It may be administered in ten-drop doses every two hours if necessary. In the treatment of hæmoptysis, this remedy is very conveniently administered by inhalation. It is volatile at a low temperature, and a copious vapour can be driven off in a very simple manner.

Take any convenient vessel, partly fill it with hot water; float upon the surface of the water, or suspend over it, a shallow dish like a plate or saucer,

upon which has been poured a small quantity (3i) of turpentine, and let the patient inhale the vapour as it arises. In this manner a gentle evaporation of the remedy can be produced which can be inhaled without inconvenience. When administered in this manner, it is especially applicable to those cases in which small hæmorrhages occur, continuing for a number of days. The inhalation may be repeated three, four, or more times a day. Strangury is only rarely produced.

When the hæmorrhage is profuse, the most certain remedy is to withdraw a given amount of blood from the general circulation. This can be done first by means of dry cups. Cover the chest anteriorly and posteriorly, and the thighs, if necessary, with the cups. If a still more powerful means be wished, resort to ligation of the extremities. Place a ligature around an arm, making it sufficiently tight to arrest the venous circulation, but permit the arterial circulation to go on. Do not retain the ligature longer than six or eight minutes upon any one limb, and when it is removed, loosen it gradually, thus gradually permitting the blood to again enter the circulation. Two or three minutes before removing the first ligature, a second one may be applied to the opposite arm, and in this manner all the extremities may be subjected to ligation. The amount of blood that can be retained from the general circulation in this way is large. Hæmorrhages may be instantly and repeatedly controlled by resorting to this measure. In a number of cases hæmorrhage precedes the cough.

Hectic Fever and Night-sweats.—The fever is one of the principal symptoms which will engage the attention of the physician. Hectic and diarrhoea sometimes alternate. For the fever, administer quinia in doses sufficient to diminish the temperature and control the pulse. An average dose is grs. xx. a day. In occasional cases the remedy produces no marked effect. Another method is to produce ringing in the ears with quinine, and continue the remedy just short of producing that effect. The fever is very commonly controlled by these methods.

For the sweats, it should first be decided whether anything is to be done for their arrest. The sympathetic action between the skin and mucous membrane of the lungs is to be taken into consideration. A sudden arrest of the sweats may do more harm than good. They are, however, sometimes so severe that they must be checked if possible. The following are among the means which may be resorted to for that purpose.

Sponging with hot water before the patient goes to bed.

Sufficient flannel clothing to furnish a change whenever the patient awakes and finds himself in one of these sweats. Change the clothes at once, when sweating occurs, immediately preceding the change by sponging with hot water.

Arouse the patient a short time before the time for the occurrence of the sweat, and have him bathe his hands and face and take a light lunch.

A large dose of quinine before going to bed. In the experience of some, quinine hardly ever does any good in hectic or habitual sweats.

Aromatic sulphuric acid in 15 drop doses, and increased by 5 drops till 40 or 45 drops are taken at a dose. Its action is slow, but sometimes beneficial.

A pill of 5 grains of oxide of zinc and 3 grains of extract of hyoscyamus, or of 2 grains of oxide of zinc, may be given three times a day. The zinc and its

combination with hyoscyamus are regarded as excellent.

Fluid extract of ergot in drachm-doses at bedtime is very beneficial in some cases. If retained by the stomach, it is quite apt to be of service.

Ergotine may be used hypodermically; atropine in such doses as will produce some dilatation of the pupil, one-sixtieth to one one-hundredth of a grain. A single dose should be given at bedtime.

Hydrate of chloral given in a twenty-grain dose about two hours before the hour for sweating arrives has been attended with success.

Cod-Liver Oil.—Whenever the patient is losing flesh and strength use the oil. That preparation of the oil which is the most agreeable to take is to be preferred. Möller's cod-liver oil is regarded as a superior article. Give it in combination with an alkali. Lime-water answers a very good purpose as a vehicle.

Oil with the phosphates answers well; and when the stomach is sensitive, the addition of two minims of dilute hydrocyanic acid to each dose is very beneficial. Commence with drachm-doses and gradually increase to half-ounce doses three times a day, which is regarded as a sufficient quantity. Give it just before or just after meals, according to the choice of the patient.

When the oil 'rises upon the stomach,' if the patient will educate himself to catch his breath, open his mouth, permit the bubble to burst as it reaches the fauces, and then blow his breath out, he will avoid all the disagreeable taste attending the eructations. This simple piece of strategy has enabled many patients to continue the use of the oil, where, before being instructed relative to it, they had been entirely unable to take it.

Nutrition can be very much supported by inunction with cod-liver oil. When oily food is not readily assimilable, 'pancreatic emulsion' is, in many cases, very serviceable.

Oxygen is of doubtful efficacy as a permanent remedy. It may give some relief. It is not to be lost sight of, and is worthy of trial.

Swelled Feet.—This symptom is regarded by the laity as one of the latest in the disease. Very great relief can be given to the patient by supporting the weakened vessels with a flannel bandage, smoothly applied.

Fistula in Ano is a complication not very infrequently met with in cases of consumption. In case the nutrition of the patient is good, and the fistula is not extensive, an operation may be performed, but the question should always be carefully considered. The liability is, that it will not heal.

FRÄNKEL AND ORTH ON TWO CASES OF MALIGNANT PUSTULE IN ADULTS.

The singular and fatal malady known by this name amongst ourselves, to which the French give the name of Charbon, and the Germans that of Milzbrand, though happily rare in England, does occur occasionally amongst cowkeepers, butchers, and others who have to do with cattle or horses; and on this account the careful description of two such cases given by Dr. B. Fränkel, and Dr. J. Orth, in the *Berliner Klinische Wochenschrift* for June 1 and 8, 1874, deserves to be transferred, with slight abridgement to our columns.

Both patients were admitted into the Augusta

Hospital at Berlin, the second being a sick-warder, and *post mortem* room assistant in that institution. The first patient, Robert Jaen, was employed in some railway-works, was forty-two years of age, strongly built, and had previously enjoyed good health. He was admitted an in-patient on January 31 last, for an inflammatory swelling of the neck. Dr. Fränkel saw him next day. He had a scab, rather smaller than a sixpence, on the left side, just under the chin, surrounded with much redness and swelling. The scab itself had nothing suspicious about it, resembling from first to last a pustule of acne which had been scratched. He said he had had a 'pimple' there for a few days, and he scratched it because it itched, and the redness and swelling then set in. The latter symptoms extended from the neighbourhood of the scab over the whole of the front of the neck, and on the right side over the clavicle, ending below in a sharply defined border over the deltoid and first intercostal space. The redness exactly resembled erysipelas: the swelling was doughy and non-fluctuating, and several hard bodies, like swollen lymphatic glands could be felt in it. These could be best made out beneath the sterno-cleido-mastoid, by feeling externally, and with a finger in the pharynx at the same time. His intellect was perfectly clear, and he only complained of pain in the inflamed parts, and when he moved his head. His temperature was 39.3°C . ($=102.7^{\circ}\text{Fahr}$). Not unnaturally, the wound was supposed to be infected, but all inquiries in this direction were nugatory. When asked if he had in any way come into contact with cattle infected with this pest (*Milzbrand*), he answered decidedly in the negative. Next day his temperature reached 103.4°Fahr ., and the redness extended still further in a downward direction on the right side. Swallowing became difficult, and the mucous membrane of the pharynx became swollen, and of a dusky red. His thirst was extreme. On February 3 his morning temperature sank to 100.4°Fahr ., and in the evening to 98.6°Fahr . Simultaneously the swelling and redness were somewhat lessened. In the evening, however, he became pulseless, and cyanotic, and died so, without losing consciousness. Shortly before death there was slightly noisy respiration, but no hoarseness.

The body was examined on February 5. The whole of the cervical connective tissue was infiltrated with reddish serum. This sanguineous infiltration, following the course of the trachea, extended into the mediastinum, along the bronchi, and over the pericardium. At the same time it followed the œsophagus, and was found in the greater and lesser omentum, and more particularly in the whole extent of the mesentery. Everywhere, along with this œdema, the lymphatic glands were enlarged, some to the size of walnuts, and so swollen with dark blood as to strongly resemble blood-clots. The spleen was considerably enlarged, and extremely soft. In the abdominal cavity was about a pint and a half of serum, free from blood, with a few turbid flakes. The lungs and the heart exhibited nothing striking. The pharynx, larynx, trachea and stomach were sent to Dr. Orth, whose report will be found further on.

Professor Virchow having diagnosed malignant pustule from these appearances, fresh inquiries were made; and it then appeared that the man had been employed in ripping up the old cushions (stuffed with hair) of railway-carriages. It appeared on further inquiries that new cushions were sometimes

stuffed with a mixture of old and new hairs—sometimes cow's hair was used. New hair was disinfected before using; but whether the patient had handled it before disinfection is not known, since whilst he was alive there was no clue to this possible and probable source of infection.

The second case is very striking as regards infection. The sick warder, Julius Körwig, aged twenty-six, previously strong and healthy, sewed up the corpse of the previous patient after the necropsy, and felt ill on February 12, seven days after the *post mortem* examination. On the 13th he presented himself as a patient, and Dr. Fränkel saw him on the 14th and 15th. Between the fingers of his left hand he had slight abrasions (*Schrunden*) of the skin, and on the 13th red streaks of inflamed lymphatics appeared on the left forearm and arm, with swelling of the lymphatic glands in the left axilla, and redness of the axillary region. The reddened lymphatics grew paler next day, but the patient complained of great weakness, and dyspnoea. On the morning of the 15th he was pulseless and cyanotic, and died in the afternoon of the same day, in full possession of his senses. His temperature chart was strikingly like that of the former patient, and was as follows: February 13, morning, 104.1°F ., evening, 105.1°F .; 14th, morning and evening, 102.3°F .; 15th, it sank to 96.8°F . He had great thirst, and during the cyanosis, the heart-sounds were slow and scarcely audible. Respiration was deep, and slow. His blood examined, at noon on the 15th, with a strong inversion lens, gave negative results as to bacteria, but it was only examined this once. Dr. Orth made the *post mortem* examination.

This case was undoubtedly one of the direct transmission of the contagion of malignant pustule. No other source of contagion, save the corpse of the first patient, could be traced. This man sewed up the body on the 5th, and took the specimens to the Pathological Institute on the 6th. Inoculation might have taken place on either day, giving either seven or six days as the period of incubation. The slight crack between the fingers of the left hand was no doubt the channel of inoculation. The usual localisation of the malignant pustule was wanting. There was no carbuncle, nor was the usual œdema observed at the place of inoculation. Had no surgeon seen the reddened lymphatics, and had the man not been under medical care, the case might have been set down as one of primary infection without any local inoculation. But the localisation was clear enough here, not by carbuncle, or œdema, but like septic poisoning, by lymphangitis. But the anatomical examination showed that the case was of true 'malignant pustule' or *Milzbrand* poisoning, and not that of ordinary septic infection. (See Korányi on *Milzbrand*; *Pitha and Billroth*, vol. i., part 3, p. 166). Dr. Fränkel notes how slight were the lesions in the heart, compared with the intensity of the cardiac symptoms which proved fatal.

The further examination of these cases was conducted by Dr. Orth, at the Pathological Institute, who reports that in the first case there was great œdema of the mucous membrane of the larynx, not only above the vocal cords, but around and below them. Indeed, the vocal cords were quite a centre for the hæmorrhagic infarction. There was no ulceration, except in the tonsils, one of which was almost destroyed by ulceration. The lymphatic glands of the throat were some of them as large as cherries, and their parenchyma changed into a soft,

dark, and blood-soddened material. The mediastinal connective tissue, like that of the neck, was oedematous and blood-stained. The lungs, though congested, were otherwise normal. The whole mucous membrane of the stomach was greatly swollen, pulpy, and reddened. In five or six large spots there was especial swelling, partly due to extravasated blood, partly to local gangrene, with a greenish-yellow tint. This appeared, not only on the surface, but on section. Professor Virchow pronounced the case to be one of malignant pustule directly he saw this stomach. The microscope confirmed this, for not only on the surface of these greenish-yellow spots, but also in the parenchyma of the gastric walls, there were found enormous quantities of the parasitic elements generally known by Davaine's name of Bacteridia. For the most part these appeared as masses of felted, but not branching, threads, which were seen, at the edges of the groups, to be composed of a number of little rod-like bodies of equal length. There were also masses, though less numerous, composed of groups of equal-sized granules (micrococci). It was now clear that the case was one of the so-called mycosis intestinalis, a special form of the pest known as *Milzbrand*, or spleen-gangrene, or malignant pustule; and the marked swelling and hæmorrhagic appearances of the mesenteric and retroperitoneal lymphatic glands, the softened spleen, sanguineous oedema of the connective tissue of the abdominal cavity, ascites, etc., described by Dr. Fränkel, perfectly agreed with the descriptions given by other observers (see E. Wagner, *Archiv der Heilkunde*, 1874).

The appearances in the second case were very similar, as regards the lymphatics, etc. There was a little fluid in the pericardium. The heart was of normal size; its walls were thick, and remarkably dry on section, shiny, and spotted, dark red spots mingling with lighter portions. The valves were not affected. The cavities were all filled with much quite fluid, dark cherry-red blood. The lungs were much congested. There was a small hæmorrhage in the lower part of the upper lobe of the right lung. Both lungs were adherent from old mischief. The appearances in the abdomen were like those in the last case, including the stomach. There was much ascites. The spleen was somewhat adherent to the diaphragm, and enlarged (6½ in. long, 4¾ in. broad, and 3¼ in. thick.) The whole organ was softened; a hæmorrhagic block was found on the upper convex surface, and small ones elsewhere; the edge was rather firmer, and follicles could be recognised. The duodenum participated in the stomach-changes, and so did all the intestine, though in less degree. The kidneys and liver had suffered less. Bacteridia in masses were found in the blood of the heart (examined at once) and on the next day in a mesenteric vein. The white corpuscles were increased. No movements were seen in these bacteridia; but that they were not coagula of any kind, was shown by their having kept perfectly well for some months with acetic acid. The blood had carried these into all the organs, but in the gangrenous-looking spots in the intestines there were no rods or fibres, but heaps of micrococci.

This is the first published case of direct communication from man to man, though Leube and Müller's cases (*Deutsches Archiv für Klin. Med.*) show that such transmission has been suspected. Dr. Orth inoculated a rabbit with the fresh blood of the second case, and from this one another, and so on

till the eighth in the series had been reached, by injecting the blood under the skin, in small quantity. They all died in from twenty-four to forty-eight hours. There were no coarse (macroscopic) *post mortem* changes in these animals, except considerable local oedema of the connective tissue and muscles at the seat of puncture, with small hæmorrhages; but the blood and the connective tissue furnished, in all the animals, great masses of bacteridia (rods and threads). In the internal organs they were present as isolated rod-like bodies. There was not the slightest impairment of the infective quality or contagion in the last experiment—which again perfectly coincides with the parasitic theory of the disease. [The authors entirely omit any mention of the measures adopted in the hope of relieving or curing this frightful malady, in either case. Were incisions made, or any other treatment employed?—*Rep.*]

W. BATHURST WOODMAN, M.D.

ON THE PRESENCE OF ABNORMAL CELLS IN THE BLOOD IN RELAPSING FEVER. BY PROFESSOR PONFICK, OF ROSTOCK.*

In the course of the long and severe epidemic of relapsing fever, which prevailed in Berlin in 1872 and 1873, I undertook a large number of examinations of the blood. The positive results which I derived therefrom are, I believe, calculated to open up a new series of points of view both in regard to the pathology of the blood itself, and in no less a degree to the process of relapse.

On the essential character of the facts in question I have already commented, in a communication which I made last year to the Surgical Congress, regarding a disorder of the marrow of bones peculiar to relapsing fever (*Berliner Klinische Wochenschrift*, 1873, p. 439). On that occasion, however, it was not so much the condition of the blood, as the surgically interesting affection of the bones, that formed the principal subject of my communication; and hence neither the signification nor the conjectured mode of origin of these anomalies of the blood could be discussed.

In the meantime, a further circumstance occurred which has led me to return to the subject. When, led by Obermeier's discovery, I proceeded to test my first observations during life, and, partly in concert with him, to complete them, I found in certain cases quite the same changes in the blood of living persons suffering from relapsing fever.

It has already for a long time been known to physiologists that in the blood of the splenic veins, besides the ordinary colourless corpuscles, larger forms are also found, which in their whole appearance agree with certain elements of the pulp, and are further characterised by an abundance of fatty granules. That these forms may, under pathological conditions, undergo an extraordinary increase, becoming unusually large and being transformed more or less completely into granular cells, I have proved in a number of diseases, starting from experimental research on animals. ('On the Sympathetic Diseases of the Marrow of Bones in Internal Diseases,' Virchow's *Archiv*, vol. lvi.)

When extremely fine insoluble pigment-granules are injected into the current of blood, these pass at once into the various tissues, especially the pulp of

* *Centralblatt für die Medicinischen Wissenschaften*, May 23, 1874.

the spleen, and finally disappear, within two days at latest, from the circulation. On the other hand, from this time there are found a number, varying with the amount of injected particles, of large and small lymphoid cells in the splenic vein, and also with the portal and hepatic veins; they are thickly filled with pigment-granules, and altogether remind one of granule-cells. (See 'Studies on the Fate of Granular Colouring Matter in the Organism,' Virchow's *Archiv*, vol. xlviii.) This presence of artificial granule-cells in the blood, which has been confirmed in all points by Hoffmann and Langerhans ('On the Retention of Cinnabar injected into the Circulation,' Virchow's *Archiv*, vol. xlviii.), appears so much the more remarkable, that it may be observed even after weeks and months have elapsed.

In reference to this point, the next thing to be done was to examine the condition of the blood of the splenic vein in all the various diseases which are attended with acute swelling of the spleen, especially those in which the introduction of very minute foreign bodies into the blood-current might, with more or less probability, be assumed; viz., the infectious diseases. In fact, it was found that, both in all the splenic swellings in infectious diseases, and also in a less degree in those met with in simple inflammatory diseases, the abnormal constituents of the splenic pulp—blood-corpuscles, pigments, and granule-cells—were found alike in the blood of the splenic vein, in proportions corresponding with the disease under observation. There were thus established a complete analogy between the morphological condition of the splenic pulp and the blood leaving it, both in infections and simple enlargement of the organ. In the absence of the connecting link of the chain of observation, we must for the present abstain from deriving from the morphological analogy one relating to pathogeny.

In correspondence with the size of the splenic tumour in relapsing fever, and the extraordinarily large number of pulp-cells, which here undergo fatty and pigmentary change, I found in this disease a remarkably large number of these also in the splenic blood. Extended research, however, showed that in high degrees of splenic enlargement their occurrence was not, as in other cases it always is, limited to the portal and hepatic veins, but that they can be found, although in smaller quantity, in other parts of the circulation. In individual cases these cells were so widely diffused through the whole body, that specimens of them could be detected in every drop of blood drawn from any part of a patient.

Such a contamination of the mass of the blood, not by fluid but by solid substances, by cellular elements foreign to it, has hitherto, so far as I know, been ascertained only in relapsing fever; and so far is practically of pathognomonic importance. For, in the intervals between the attacks, when Obermeier's filaments are constantly absent, their presence will remove any doubts as to the true nature of the disease.

Whether it be really correct to assume that all these cells have their origin in the splenic pulp, cannot at present be exactly determined. In the meantime it seems to me as if this explanation is in harmony, for the most part, with facts otherwise ascertained, and especially with the results of experiments. Under this supposition, the general diffusion will have to be explained by assuming that, in consequence of the extremely profuse development of the cells in the pulp, such as generally accompanies the highest de-

gree of splenic enlargement, they pass into the blood-current in such quantity, that the vascular regions, which in other cases remain free from them, become more and more inundated. Indeed, the splenic tumour in relapsing fever surpasses in circumference all others of acute origin; and it attains an extraordinary size in those cases especially in which a change in the blood can be detected during life.

Along with these granular masses I have also—during life—sometimes found in the blood other foreign cells, which must not be confounded with them. The best marked specimens of these are distinctly to be recognised as endothelial cells from the vessels; but, as they have always undergone more or less fatty degeneration, they may, when this process has gone on to an extreme degree, present a certain resemblance to the cells already described. But, while the endothelial cells appear flat, or at the most lentil-shaped, the others are always distinctly globular or elliptical.

This hitherto unobserved occurrence within the living blood-current of endothelial cells which have undergone fatty degeneration, reminds me of an observation which I made some time ago (*Deutsche Klinik*, 1867, nos. 25 and 26), that extensive fatty change of the endothelium of the blood-vessels occurs under the influence of certain infectious diseases. In relapsing fever, this change probably reaches so high a degree that the changed cells must be thrown off in large quantities, and be carried into the blood-current. In other diseases, the destructive process appears to be confined within too narrow limits, or to go on too slowly, to allow the separated cells to be detected in the examination of a small quantity of blood.

According to these observations, we have to recognise three sources of contamination of the blood in relapsing fever. While the occurrence of Obermeier's filaments may be well referred to importation from without, the presence of the cells of both kinds must be regarded as arising from internal or self-infection. Further researches on the blood will have to be made, to ascertain the further fate of these swimming cell-corpses; and the question will especially have to be investigated, whether they may not of themselves produce new disturbances, especially embolism and its results.

LOCKHART CLARKE ON THE MORBID ANATOMY OF PROGRESSIVE MUSCULAR ATROPHY.

In a very valuable pathological contribution (*Medico-Chirurgical Transactions*, vol. lvi. 1873) Dr. Lockhart Clarke has described the microscopical appearances observed in a case of muscular atrophy, accompanied by muscular rigidity and contraction of the joints. The parts received for examination were a slice of one of the cerebral hemispheres, the cerebellum, pons Varolii, medulla oblongata, and spinal cord. The white substance of the brain was rather thickly interspersed with corpora amylacea, from about twice the diameter of a blood-disc to fourteen times that size. In the grey substance only a few of these bodies were present, and they were confined chiefly to the deeper layers.

It is here worthy of note that in chronic disease of the brain and spinal cord the presence of bodies, of varying size and far from uniform aspect, to which the name of amyloid bodies is generally given, is by no

means uncommon. At the same time, there are forms of degeneration of the neuroglia, which give rise to appearances so closely resembling the so-called corpora amylacea that it is an extremely difficult thing to distinguish between them. Minute spots of miliary sclerosis, and of colloid, are often to be seen in the same sections with the supposed amyloid bodies. The chromic acid, or other means employed to harden the nerve-substance, so far alters its condition that the reactions of iodine or other tests for cellulose are controlled or obscured.

Dr. Clarke notes a dilated condition of the vessels, and in some parts a disintegration of these to the extent of causing their entire disappearance, with a consequent production of large empty and smooth-walled tubular spaces, which, according as they were cut transversely or obliquely, presented an appearance of round or oval vacuities. This appearance was first described by the author in a case of general paralysis of the insane, (*Journal of Mental Science*, January, 1870), and has since been noticed also by other observers. It formed the most prominent feature of the lesions described by Dr. Dickinson in the medulla oblongata from several cases of diabetes. Dr. Clarke also refers to the dilated condition of the vessels, in connection with those spaces around them which have been spoken of as 'lymphatic spaces,' or 'perivascular sheaths;' but which, the reporter has endeavoured to show, are the results of pathological, or even of merely *post mortem* changes.

The cells of the cerebral grey substances in this case were not altogether healthy. Some of them had lost their natural sharpness of outline; others contained rather more pigment than usual, or were somewhat granular at their surfaces. The pigmentation of cells was still more observable in the medulla oblongata. This change is considered by Dr. Clarke to constitute the first stage in the degeneration and subsequent disintegration of nerve-cells. The medulla oblongata was one-fifth below the average size, and the diameter of the spinal cord was reduced by at least one-fourth; so much was it reduced that when first seen by Dr. Clarke, without any explanation, he thought it was the cord of a child of fourteen years of age.

The grey matter of the cord presented a variety of lesions. Congestion of the white columns was present. Hypertrophy of the connective tissue, with proliferation of its corpuscles, and aggregation of these in masses at the angles of junction in the network, are described by the author, and illustrated in an engraving. Several patches of disintegration were observed. One of large size consisted of small remnants of partly disintegrated grey substance, irregularly connected with each other, and forming together a kind of reticular or honeycomb structure. Several large areas of disintegration and hæmorrhagic clots existed, involving large portions of the cord in destruction. In all regions of the cord, the nerve-cells had undergone degeneration and disintegration. Some were completely, others only partially, filled with dark brown pigment-granules, which in many instances enveloped and concealed their nuclei. All the remaining cells were reduced in size; many seemed to have been lost by gradual atrophy, and numbers had wholly disappeared by complete disintegration, or fallen into granules. The several stages of the process could be followed.

We have very imperfectly followed Dr. Clarke in the details of the changes he records. They are well and clearly shown in the drawings by which

the paper is accompanied. As the author remarks: 'The symptoms in this case are very clearly explained by the morbid changes that were formed in the medulla oblongata and spinal cord. Lesions were traced in the nuclei of the facial, hypoglossal, vagus, and spinal accessory nerves, and explained the symptoms of glosso-pharyngeal paralysis. The extensive loss of substance in the anterior and lateral grey substance of the cervical and dorsal regions, more especially of the *tractus intermedio-lateralis*, explained feebleness of respiratory movements, while progressive changes of similar character in the lumbar and dorsal regions of course explained the paralysis of the upper and lower extremities.'

W. B. KESTEVEN.

ANATOMY AND PHYSIOLOGY.

VULPIAN ON THE JUNCTION OF SENSORY AND MOTOR NERVES.—Physiologists are acquainted with the experiments made by M. Vulpian, along with M. Philipeaux, several years ago, with reference to the point, whether nerve-fibres anatomically alike were similar also in their physiological qualities. They joined the peripheric end of a motor nerve, the hypoglossal, with the central end of a sensory nerve, the lingual. In three or four months the union was complete, and the peripheric end of the hypoglossal nerve, which had been altered through the operation, had recovered its normal structure. On then stimulating the lingual nerve, considerable movements were produced in the corresponding part of the tongue.

M. Vulpian has, more recently, found reason to question the truth of his inference from these experiments; for he observed that one of the branches of the chorda tympani accompanies the lingual nerve in its distribution to the tongue. Thus the lingual nerve contains, throughout its course, anastomotic fibres proceeding, by the chorda tympani, from a motor nerve, the facial. He inquired what rôle was to be attributed to this anastomosis, in the physiological change undergone by the lingual nerve when the hypoglossal of the same side has been cut; and he found that the lingual nerve then acquires, in a few days, a motor action on the tongue, which it has not in the normal state.

The fact once ascertained, it became necessary to further inquire if the excitations produced in the central end of the lingual (in the experiment of uniting the lingual and hypoglossal), after the peripheric segment of the hypoglossal is regenerated, are transmitted to this segment by sensory fibres of the lingual nerve, or by anastomotic fibres of the chorda tympani. M. Vulpian has made a number of experiments on dogs with this object (*Comptes Rendus*, June 26). Six of the animals survived long enough to give satisfactory results. The procedure was as follows. The central end of the lingual nerve was joined with the peripheric end of the hypoglossal nerve, by a suture-point; the central segment of the latter nerve having been extracted, and also a long piece of the peripheric segment of the lingual. Three or four months after this, the author cut the chorda tympani on the same side, in the tympanic cavity; and ten or twelve days after the section, the central end of the lingual nerve was laid bare. It was cut across as high up as possible, and the part in connection with the hypoglossal nerve was irritated

with electrical or mechanical stimuli. Not the least contraction was observed in the corresponding part of the tongue. (The union was ascertained to have been complete, and the peripheric end of the hypoglossal was regenerated.) In the case of one dog, the junction was made on both sides, but the chorda tympani was only cut on the left side. On irritating the left lingual with interrupted currents, no movement took place in the left half of the tongue; whereas electrification, or pressure with forceps, of the right lingual gave rise to very distinct contraction in the right half of the tongue. (Here, too, it was made sure that the junctions had been complete on both sides.)

It would appear (from some further observations), that most of the fibres that are regenerated in the peripheric segment of the hypoglossal, when this nerve has been united with the lingual, have not, at least for some time, any action on the muscles of the tongue; and that if movements of the tongue be produced by electrifying this nerve-segment, the excitation is conducted to the muscles only by a small number of fibres, viz., by those which are in relation with the fibres of the anastomotic branches given to the lingual by the chorda tympani. Thus either the greater number of regenerated fibres in the hypoglossal segment do not at once take their normal relations with the muscular bundles of the tongue, or these regenerated fibres are essentially merely prolongations of fibres of the central end of the lingual nerve, and, like them, are incapable of inducing contraction. In any case (M. Vulpian concludes), the experimental facts described show clearly that the experiments of uniting, end to end, the lingual and hypoglossal nerves cannot any more be cited as proving that electrical or mechanical excitations of the sensory nerves can be freely transmitted to motor fibres. * Our former experiments were exact, but the interpretation we gave them, and which has been adopted by the majority of physiologists, was erroneous. The new ideas we have acquired as to the physiology of the chorda tympani could alone indicate the error. The results of our present experiments, however, cannot be considered as a peremptory refutation of the opinion of physiologists, which represents that sensory, motor, and sympathetic fibres have the same intrinsic physiological property, neurility, a property which in action gives rise to different functional effects, according to the central and peripheric connections of the nerve-fibres in which it appears. The question of identity of physiological property in all nerve-fibres remains a disputed one, and it is difficult to foresee in which way it will be decided.

ALEX. B. MACDOWALL.

MÜLLER ON THE DEPENDENCE OF THE ARTERIAL BLOOD-PRESSURE ON THE QUANTITY OF BLOOD.—Dr. Worm Müller (*Ludwig's Arbeiten*, vol. viii. p. 159; and an abstract in *Centralblatt für Chirurgie*, nos. 8 and 10) under Ludwig's direction, has investigated this subject, and has arrived at results fraught with importance not only for the practice of blood-letting, but also for that of transfusion. The author regards his paper merely as a preliminary one.

The experiments of Goltz made upon frogs (*Virchow's Archiv*, vol. xxix. p. 394), and those of Tappeiner (*Ludwig's Arbeiten*, vol. vii. 193), upon rabbits, have shown that a considerable quantity of blood can be withdrawn from these animals without influencing in a corresponding degree the rapidity of

the current, and the pressure in the large arteries arising from the aorta.

The author's experiments were always made upon dogs. He has established this remarkable fact, that the vascular system can accommodate very large quantities of blood without there being any marked increase of the normal arterial blood-pressure, which was always measured in the carotid. More than sixteen per cent. of the body-weight of the animal in blood could be injected into the jugular vein, without (after the termination of the injection) the blood-pressure in the beginning of the aortic system becoming markedly higher than it was in the normal dog before the commencement of the experiment; i.e. the quantity of blood that the animal originally had could be increased to three times its original amount without producing any marked increase in the arterial blood-pressure. Within certain limits this also holds if the blood-pressure have been lowered, either by section of the spinal cord or by blood-letting. As soon, during the injection, as the blood-pressure had reached the value noted before the beginning of the experiment, the addition of several quantities of blood did not raise the pressure above the normal. That the blood, in spite of the overfilling of the vascular system, remained within it, and that no important exit of blood or blood-plasma took place through the walls of the vessels, was established by the negative results found on very careful *post mortem* examination of the animals experimented on. To dispose of the idea of a simple serous exudation, the thoracic duct was opened to observe the outflow of lymph during and after the injection of the defibrinated blood. The rapidity of the lymph-current increased with the quantity of blood added, but a sinking of the blood-pressure with increased quantity of lymph was not observed. A direct proof of the overfilling of the vascular system is given in the effects of blood-lettings in an animal previously injected. From an animal into which blood had been previously transfused, quantities of blood not sufficient to endanger the life of the animal were withdrawn from the carotid. From such an animal, overfilled as it was with blood, on continuing the blood-lettings until death ensued, and even by pressing the limbs and body of the moribund animal, scarcely ever was the quantity of blood which was transfused again recovered. The results of the *post mortem* examination showed no marked overfilling of the arteries, and only in the veins of the abdomen was there an appreciable overfilling observed. The author is of opinion that after transfusion the blood is specially to be found in the capillaries, distributed more or less over the whole body. He is further of opinion that the increase in the capacity of the vascular system is accomplished by the help of the capillary nets, of the smallest veins, and smallest arteries. Very probably, throughout the whole body under normal conditions many capillaries, entirely empty, or only partly filled, exist, which become permeable for the blood-current, after considerable increase of the quantity of blood. An expansion of the capillary networks is not a necessary consequence of the overfilling. This occurs, however, under very pronounced filling of the vascular cavities with blood, and, as the author believes, at those places, and in those organs, such as the thoracic and abdominal cavities, where the overfilling is most observable.

Even with pronounced filling of the vascular system no change in the capacity of the heart for action

(*Leistungsfähigkeit*) occurred. The pulse-beats remained, with increased percentage of blood, either unchanged, both in animals with divided and in those with intact spinal cord, or they were diminished so irregularly that the latter point could only, under certain circumstances, be brought into count. The heart's working power remained undiminished. The lungs were found congested *post mortem*. An increased friction of the blood in the lungs is not alone sufficient to explain the non-increase of the blood-pressure. Neither congestion of the right heart nor of the large veins which open into it were found.

If, after transfusion, the quantity of blood in the transfused animal were diminished, the paradoxical phenomenon was exhibited, that before one half of the blood injected was recovered, the arterial blood-pressure sank much below the height which it normally had before the transfusion. By continuing the blood-letting, the animal could be brought near to death, even although the quantity of blood which it had surpassed, by several per cents. of its body weight, the original (normal) quantity of blood; in other words, animals which had received from one to three times their original quantity of blood were much more sensitive to blood-letting than in the normal condition. They yield absolutely more blood on being bled to death, which is easily explained by the strongly pronounced filling of the vascular system; but relatively they require much larger, perhaps twice as large, or may be still larger quantities of blood (than in the non-transfused condition), in order to preserve the normal blood-pressure, *i.e.*, that necessary for life. In an animal which has been bled nearly to death from both carotids, even after blood has ceased to flow from the divided arteries, blood again flows from the carotid on dividing the cervical spinal cord, and the stream is increased on raising the posterior extremities and pressing on the abdominal and thoracic walls. The author then discusses the upper and lower limits of the physiological filling of the vascular system, and then follows a short chapter on plethora and transfusion.

BIDDER ON HYPERTROPHY OF THE EAR AFTER EXCISION OF A PORTION OF THE CERVICAL SYMPATHETIC IN A RABBIT.—Alfred Bidder (*Centralblatt für Chirurgie*, no. 7, 1874), excised a piece ($1\frac{1}{2}$ centimètres in length) of the left cervical sympathetic from a half-grown rabbit. This was followed by the usual symptoms which result from the section of the cervical sympathetic. In about a month the rabbit had grown just as the other rabbits, and appeared quite sound. The left pupil was only half as large as the right, and the left eyeball projected much less from the orbital cavity than the right. The left ear was distinctly broader and longer than the right, and was more hyperæmic and warmer. A fortnight later, the difference in size was more striking. The author attributes the increase of the size of the ear to the increased continued supply of blood to the ear of the young animal, where all the nutritive processes are going on actively.

WILLIAM STIRLING, D.Sc., M.B., Leipzig.

DISEASES OF CHILDREN.

RIEFKOHLE ON THE OCCURRENCE OF MECKEL'S DIVERTICULUM IN TWO CHILDREN OF THE SAME MOTHER.—It is well known that the remains of the

omphalo-mesenteric, or vitelline duct, not unfrequently take the form of a diverticulum or pouch-like appendage at the lower end of the small intestine. The cases now recorded, the original of which will be found in the *Berliner Klinische Wochenschrift* of May 25 last (no. 21 for 1874), are of interest, from the fact of two children at least, of the same mother, presenting the same anomaly, or malformation, if it be correct to apply such a name to the persistence of a foetal structure. Dr. Riefkohl, who is a medical officer of health, says that the mother, Mrs. K—, had herself, prior to her marriage, suffered much from dyspepsia, with colic and constipation. Since her marriage in 1870, she had been tolerably healthy, though anæmic. She suckled her first child, and he thrived pretty well, till he was four months old, when he began to suffer with obstinate constipation and pains in the belly; troublesome tenesmus followed the use of purgatives, and his strength and general nutrition were seriously impaired. Dr. Riefkohl only saw him shortly before his death (in April, 1872), and diagnosed cerebral mischief, on account of his exhaustion and convulsions. The second child was born in September, 1872, and though not suckled, did very well till four months old, when similar symptoms to those of his brother set in. The bowels became irregular, and he began to scream about an hour after taking food; his features were distorted, but occasionally he obtained relief after vomiting. His strength declined from day to day, and he died in convulsions about the middle of February, 1873. On opening the abdomen, there were no signs of inflammation, but about five fingers' breadth above the cæcum there was a so-called Meckel's diverticulum, which arose from the convex border of the ileum, at right angles to that portion of the bowel, and of somewhat smaller calibre; its length was about $1\frac{1}{2}$ inch. Its rounded extremity was quite free. Mrs. K— had another son born on November 23, 1873, who appeared to do well for three months only, and then suffered from the same frightful symptoms as his brothers. Wet-nursing, cow's milk, meat-broth, Nestlé's children's food, every kind of nourishment produced, after an hour or two, griping pains, followed by vomiting. Urine and fæces were sometimes suppressed for several days. No treatment brought relief (ethereal mixtures, opiates, both internally and as suppositories, fomentations and other means were used), but the child died anæmic, with convulsions, in March, 1874. The necropsy showed nothing abnormal in the abdomen, except, as before, a diverticulum of the ileum, about four fingers' breadth from the cæcum, an inch in length; this one branched off at an acute angle from the convex border of the ileum, was somewhat narrower than the bowel, and was connected with the mesentery by a ligamentous cord. Dr. Riefkohl asks whether the fatal symptoms, in the three cases recorded, may be considered as originating in disturbances of digestion due to the presence of this diverticulum of the intestine. [The reporter, without wishing to reply too dogmatically in the negative, contents himself with remarking that similar diverticula have been found in the bodies of adults who have died of other diseases; although in other cases they have been the causes of intestinal obstruction, by forming a nidus for foreign bodies.—*Rep.*]

W. BATHURST WOODMAN, M.D.

KLEMM ON THE CURABILITY OF TRUE CROUP WITHOUT EMETICS.—Dr. Klemm narrates (*Fahr-*

buch für Kinderheilkunde, vol. vi.) a case of croup which was treated by packing in the cold wet sheet. The packing was repeated every three or four hours for the first day or two. The child recovered. Three other cases, similarly treated with the same result, are alluded to. Klemm deems the sweating which accompanies the packing to be not less beneficial than the abstraction of heat. It is important that the treatment should be begun early in the disease, before the false membrane has been abundantly formed.

STEINER ON MORBILLI BULLOSI SIVE PEMPHIGOIDEI.—Dr. Steiner narrates (*Fahrbuch für Kinderheilkunde*, vol. vii.) four cases of measles, attended with an eruption of bullæ. The patients were sisters; and the cases are the only instances of the kind which Steiner has observed out of 6,000 of measles. The bullæ appeared on the face, scalp, back, chest, hands, feet, mucous membrane of the mouth, nose, and vulva. The blebs appeared one day after, two days after, at the same time as, and half a day before, the eruption of measles. The bullæ came out in crops, and continued to appear after the measles had ceased. One child, a baby of ten months, died in consequence of pneumonia.

SAMUEL GEE, M.D.

SURGERY.

OTIS ON URETHRAL STRICTURE AND ITS TREATMENT.—Dr. Fessenden N. Otis, in a paper recently read before the New York Medical Journal Association, and published in *The New York Medical Journal*, thus speaks of certain matters connected with the urethra and its strictures.

Chronic urethral discharge, commonly called gleet, is the signal which nature hangs out to notify the intelligent surgeon that an obstruction to the normal working of the muscular apparatus of the urethra has occurred; that plastic material, laid down in the antecedent inflammatory condition, has begun to contract the normal urethral calibre, whether it be twenty or forty millimètres in circumference, and that nothing short of a complete restoration of the normal calibre of the canal will afford a permanent cure. Sandal-oil may stop it for a time; injections of innumerable variety may, any one of them, temporarily remove it; but a little venous or venereal excess will reproduce it, and thus the case goes on, until finally an attack of retention of urine calls attention to the fact that the patient has strictured urethra.

To prevent the return of stricture after operation, the stricture must first have been thoroughly sundered at some point; that those strictures which have been permanently cured (and in this number I do not include those facetiously termed cured where the patient is obliged to use, or have used, a sound every two weeks for the balance of his life, but those that never reappear after operation) have been so sundered, either by rupture through dilatation more or less rapid, by divulsion, or division. The reason why the treatment of stricture after the usual methods is imperfect—that there is always a tendency of the stricture to return—arises from the fact that, as in the case cited, the strictures were not completely sundered at any point—that they were distended, not completely divided. All urethral

strictures are composed of elastic tissue, and any operative procedure that falls short of complete division of the constricting band can never produce more than temporary results. As long as no. 8 of the English and no. 21 of the French scales are accepted as representing the normal calibre of the human male urethra, and as long as curative treatment ceases when this calibre has been reached, there will never be radical permanent cure of urethral stricture. Sooner or later, however, it is certain to be accepted that urethræ vary in size in different individuals just as widely as any other constituent portions of the human body, and that consequently stricture of the urethra is a relative term; that while no. 8 bougie English or no. 21 French will determine the presence or absence of stricture in the urethra of corresponding calibre, it fails to recognise stricture in urethræ of larger size, which has been positively demonstrated in certain cases to reach as high as thirty-six or even forty millimètres in circumference; and that complete division of stricture, of whatever calibre, having been accomplished, recontraction may be prevented, and that thus strictured urethræ can by appropriate treatment be with certainty restored to their normal dimensions without fear of subsequent recontraction. This I do not assert unadvisedly or rashly, as the records of more than fifty cases occurring in my own experience will demonstrate. Several of these cases, in which five and six strictures were present two years ago, and then thoroughly divided, have been carefully examined by me within the last month, and can be shown to-day free from the slightest evidence of recontraction. This goes far to prove that complete division of stricture, with appropriate after-treatment, will give complete immunity from recontraction. The results of operations with the dilating urethrotome, presented by me to the profession at a meeting of the New York Medical Journal Association more than a year ago, have remained permanent; that is to say, the strictures operated on, having been thoroughly divided, were afterward completely absorbed.

Dr. Otis wishes to be distinctly understood as asserting that 'stricture, as ordinarily met with, is absolutely within the reach of curative measures; that if completely divided, and this division maintained by suitable means until healing of the parts has occurred, no recontraction can ever take place; that dilatation, temporary or permanent, is never more than a palliative measure, unless carried to a point sufficient to completely rupture the stricture; that the division of stricture is not more hazardous, to say the least, than permanent dilatation—that is, by introduction of dilating instruments, which are required to remain *in situ* for hours or days—or than rapid dilatation, which requires instruments of increasing sizes to be introduced at one sitting; and, I may venture to say, scarcely more likely to produce trouble than temporary or transient dilatation, as usually practised by surgeons, which is simply to pass a sound or bougie gently through the urethra, to be immediately withdrawn; the same to be re-introduced, at intervals of two or three days or weeks, for the rest of the natural life of the unfortunate patient.'

Dr. Otis concludes with the following. '1. Stricture may be present before difficulty in urinating occurs. 2. It is always present when gleet is present—gleet, as a rule, means stricture. 3. Dilatation of strictures is, at best, but a temporary expedient; valuable

in close stricture, where urination is interfered with, and the stricture is too close for the introduction of instruments for completely dividing it; but dilatation is not only without permanent value except in such cases, but it is pernicious, inasmuch as, while it is never curative, it takes the place of curative measures. 4. Nothing short of complete division of strictures can ever result in radical cure.'

OLLIER ON RHINOPLASTY BY A DOUBLE FLAP.—M. Ollier (*Gazette Médicale de Paris*, 1874, p. 202) refers to the hideous deformities produced in the nose, as the consequence of syphilis, and states that the wretched results procured by the old methods of rhinoplasty have caused the operation to be almost abandoned. He suggests that a flap of integument taken from the deformed nose should be combined with the frontal flap. The first and most difficult step of the operation is to dissect the soft coverings of the nose, making a sort of bridge, free in the centre, and adherent at the extremities to the cheeks. A flap is then cut from the frontal region, at least six inches long, and encroaching on the hairy scalp; its pedicle corresponds exactly to the space between the eyebrows. In young subjects, M. Ollier elevates with it the periosteum, otherwise not. The flap is then reversed without torsion, so that the cutaneous surface becomes internal, and the raw surface external: it is slipped under the previously formed bridge of integument, and the two raw surfaces are fastened together to prevent retraction. When the point of the nose is absent he turns up the end of the flap, so as to replace it, and at this first operation he bestows no attention on the formation of the nares or septum. After the operation the frontal flap first swells, and then unites to the deep surface of the nasal flap; the uncovered portion cicatrises after granulation. It is well supplied with blood by the two frontal branches of the ophthalmic artery, which pass through its pedicle; the pedicle is never divided by M. Ollier, and thus the atrophy observed after other modes of operation is avoided. The further procedures consist in modelling the nose and preventing it from sinking down, and in forming the nares. Ollier has never observed bony formation from a periosteal flap. The periosteum has always remained fibrous, but it assists in giving firmness to the new nose. In a case where the point of the nose was destroyed, M. Dolbeau partially covered the raw surface of the frontal flap with integument taken from the cheek on each side. A similar process is recommended in Langenbeck's *Archiv für Klinische Chirurgie*, 1860; but Ollier claims precedence, as he communicated his ideas to Verneuil in 1858. The results of Ollier's operations, as shown by the photographs, appear satisfactory. The important feature in the operation is that the pedicle is not divided, and the flap therefore continues to be well nourished.

The osteogenetic power of the pericranium varies according to age, and in different animals; the bone being reproduced in lambs which had been trephined, whilst in the adult sheep, under similar conditions, no bony reproduction was observed.

KARPINSKI ON OSTEOPLASTIC RESECTION OF THE EXTERNAL NOSE, FOR THE REMOVAL OF NASO-PHARYNGEAL POLYPI.—Dr. Karpinski (*Berliner Klinische Wochenschrift*, no. 17, 1874) relates a case in which he removed a large naso-pharyngeal polypus, according to the method recommended by Professor Von Bruns of Tübingen. The advantages

of the method are: a direct approach to the insertion of the polypus, plenty of room for the introduction of instruments, facility for the arrest of hæmorrhage, possibility of keeping the wound open a long time to complete the radical cure by cauterising the pedicle of the polypus, easy performance of the operation, and union without deformity or loss of function. The patient in question was twenty-one years old, and suffered from severe hæmorrhages from the left side of the nose. The septum was pushed to the right side, the soft palate was much depressed, and there was difficulty in respiration and swallowing, with loss of hearing on the left side. The examination of the tumour was followed by severe hæmorrhage, and it appeared to be growing rapidly. The author modifies Von Bruns's operation merely so far that the outer angles of the incision are rounded in place of being angular. The bones are to be divided in the lines of the superficial incision with a key-hole saw. In the case reported by the author, when this division was half completed, hæmorrhage took place to such an extent from the right nostril, from the wound, and from the mouth, that the patient became collapsed, and the operation had to be deferred. The hæmorrhage was arrested by plugging the parts, and its occurrence was explained by the saw having injured the vascular polypus. Two days later, the operation was completed without further bleeding. The flap of bone and soft parts was turned over to the right side, and the entire nasal cavity exposed. The polypus was now easily twisted off, and a plug saturated with chloride of iron was introduced to prevent loss of blood. The following day this was removed, and a fresh one introduced; and finally, a week later, the external parts were united by suture. The nature of the tumour was myxo-sarcoma. The patient recovered with a nose of normal appearance; hearing returned, and the only deficiency was the absence of sensation in the left side of the nose.

WILLIAM MAC CORMAC.

MATERIA MEDICA AND THERAPEUTICS.

INCE ON CORTEX RHAMNI FRANGULÆ (BLACK ALDER BARK).—Mr. Joseph Ince writes as follows in the *Chemist and Druggist* for June 15.

Knowing from recent investigations that the Rhamnus frangula bids fair to be a valuable addition to our list of purgatives, I venture to bring before the notice of the reader what is at present known respecting its introduction, its history, and its remedial application.

The Rhamnus catharticus has long enjoyed a popular reputation: the botanical difference between that and the alder buckthorn (*Frangula*) is pointed out by Bentham, who describes the latter as growing in hedges and bushy places throughout Europe and Russian Asia, except the extreme north. In Britain it is rather more frequent than the common Rhamnus, but is still rare in Scotland. It flowers in the spring or early summer. An elaborate analysis of the two barks is given by M. Gerber (*Pharm. Journ.*, vol. ix. p. 537, Old Series) and commented on by M. Binswanger. The inference drawn from the results obtained was, that on the peculiar nature of the *bitter matter* depended the variation in medical efficacy.

That contained in *R. frangula* had more of the

nature of resinous than of extractive matter, and was very soluble in cold alcohol. The bitter matter of *R. catharticus* was crystallisable, soluble with difficulty in alcohol, but very readily in water; the taste also differed from that of *R. frangula*, being not disagreeable, but purely bitter.

The first memorandum on *Rhamnus frangula* is a note from Mr. George Mennie, of Plymouth, who recommends it as an aperient (April 7, 1843). When Mr. H. C. Baildon made some brief remarks on *Rhamnus frangula*, at Edinburgh, his suggestions, being very short, did not excite particular interest, but to that gentleman is entirely due the introduction of this bark. A Dutch friend, Mr. Baruchson, sent a small sample to Scotland for examination. Senna we well know, and children better; and it was claimed for the new aperient that it would act as an efficient purgative without the griping and nauseous qualities of that unhappy Alexandrian leaf. In Holland it was in constant use, being there prepared simply as a decoction. The formula was:—

Cort. Rhamni Frangulæ ʒiv.
Aque Oj., decoque ad Oss.

Dose: Two or three table-spoonfuls for an adult, night and morning occasionally.

I have tried it in that form with admirable success; but seeing that in private families few are sufficiently skilful to make an accurate decoction, and that in aristocratic circles none will take the trouble, I recommended a proof-spirit tincture, but was anticipated by Mr. Giles, who proposed a liquor, the production of which was further improved by Mr. Baildon. One precaution, however, must be borne in mind. There are two classes of bark, the one obtained from trees of older growth, or from the thick part of the trunk; the other, 'the bark of the younger trunks and the larger branches of the indigenous shrub, gathered in the spring.' This description is taken from the *Pharmacopœia Germanica*, and it is this latter variety that should alone be used. I have permission to quote the formula to which reference has just been made.

Liquor Rhamni Frangulæ (Black Alder).

R. Cort. Rhamni Frang. 60 ozs.
Exhaust by decoction (*more* Giles), and reduce to 320 fluid ounces. Add
Rectified spirit 80 ozs.
Product, 20 pints.

Mr. Giles's process will be found in the *Year-Book*, 1873, p. 258. Its object is 'to effect the exhaustion of a drug with the minimum volume of solvent by submitting it to successive contact with fresh portions of the menstruum.'

Proceeding in this manner, the reduction is effected by careful evaporation in the water-bath to a suitable consistence. Mr. Baildon uses the same proportions, but prepares his concentrated decoction *in vacuo*, and then adds the rectified spirit. The liquor is exactly three times the strength of the ordinary decoction.

It is hardly needful to observe that the establishment of a non-drastring purgative in our *Materia Medica* would be a boon of no secondary order. Numerous experiments, medically conducted, have been initiated, and with satisfactory result.

The dose of liquor *Rhamni frangulæ* is one dessert or table-spoonful, in a wineglass of water, night and morning as required. For children, in whose case its use is specially indicated, one tea-spoonful occasionally in a little water. When the

time comes for a new Addendum, I would venture respectfully to suggest that this bark, and the intrinsic value claimed on its behalf, should receive the attention of the Medical Council. It has made its way without adventitious aid, and already has been accepted as a safe, pleasant, and efficient purgative.

THORNE ON PERMANGANATE OF POTASS IN OXALURIA.—Dr. Thorne, of Chicago, praises, in the *Michigan University Medical Journal*, the use of permanganate of potass in oxaluria. He gives a case, and says:

'When we consider the fact that uric acid may disappear entirely from the urine, and that oxalic acid is not normally present, is it not fair to conclude that the uric acid must, in the normal condition of things, undergo decomposition in the body? We find that by adding an excess of permanganate of potass to uric acid out of the body, it is directly converted into urea and carbonic acid; and that when the oxidation is less complete, it passes into the form of urea, oxalic acid, and carbonic acid. If, therefore, we would prevent the formation of uric acid and oxalic acid, we must supply the seven equivalents of oxygen, and four of water. This is most conveniently done in the form of permanganate of potass.

R. Permanganate of potass grs. viij
Water ʒij. M.

One teaspoonful to be given three times a day.

'It should not be given except on an empty stomach; for, in contact with organic matter, it is decomposed, yielding its oxygen to any element, simple or compound, that will receive it. I have repeatedly directed, during the last two years, the permanganate to be given as above, in oxaluria, with the most happy result.'

KALISCHER ON TRANSFUSION IN THE TREATMENT OF CHOLERA.—G. Kalischer reports (*Inaugural Dissertation*, Berlin, 1872 and *Philadelphia Medical Times*), two cases of cholera, treated by transfusion of blood, in Berlin, during the last epidemic of this disease. In both cases the blood was injected into the basilic vein; the operation in one case being followed by recovery, and in the other by death. He reports also another case, treated in the same manner, in which the operation was followed by recovery. Among fourteen cases which he found reported in the journals, there was but one recovery. After the operation, however, there was usually noticed some amelioration of the condition of the patient, the pulse became stronger, and the occurrence of death seemed to have been retarded. A. Netter (*Gazette des Hôpitaux*) states that Lorain, after injection of water into the veins, always noticed an improvement in the general condition of the patients, and in one case in which life had been despaired of, recovery took place. The amount of water injected in this case was but 400 grammes, but the patient drank large quantities of the same fluid while under treatment. Netter agrees with Goltz in thinking that the injection of water into the veins is as satisfactory as that of blood or saline solutions, and concludes that the only use of transfusion is the introduction of fluid, by which the circulation is again rendered possible.

REYNOLDS ON ACETATE OF LEAD IN TOOTH-ACHE.—Dr. Henry T. Reynolds, of Baltimore, writes

to the editor of the *Medical News* that, for eighteen months, he has been using acetate of lead as a remedy for toothache. He finds it better than any of the numerous remedies proposed in the books, and in cases in which it is applicable, the relief is instantaneous. He advises the sufferer to apply from one to three grains to the cavity for a moment or two, then to spit it out. It fails in fewer cases than any other remedy that Dr. Reynolds ever tried—not more than eight per cent.

PUBLIC HEALTH.

ON THE USE OF ZINCED OR GALVANISED IRON FOR THE STORAGE AND CONVEYANCE OF DRINKING-WATER. BY W. E. BOARDMAN, M.D., OF BOSTON.*

(Concluded from page 369.)

With regard to the carbonate of zinc, which is ordinarily found in water drawn through galvanised iron pipes, Vauquelin and Deyeux, Devaux and Dejaer, Orfila and, recently, Bouchardat and Fonsagrives,† were unanimous in their opinion of its innocuity. Eminent chemists, physicians, and accepted authorities on *materia medica* and toxicology in Boston and its vicinity, confirm this view. This compound has been administered internally as a medicine for many years, though not very generally, its effects being considered so slight that it has been regarded as of little service. Gmelin, Merat and Lens and others, mention its employment in various affections, but make no reference to any injurious effects resulting from its use. Pereira remarks of its physiological effects, that its action is probably similar to that of the oxide. Oesterlen expresses the same opinion. Van Hasselt remarks, that it does not appear to be so harmless as some writers have asserted, referring to Leclaire, Chevallier, and others; but he bases this opinion upon the cases reported by Bouvier, whose deductions, as we have seen, Bouchut showed to be untenable, and upon those communicated by Landouzy and Maumené, which Bouchut, Chevallier, Tardieu, and others proved were not occasioned by the action of the carbonate. Dr. T. Stratton, surgeon, R.N., who treated two cases of poisoning with the chloride of zinc, states,‡ that the best antidotes are the carbonated alkalies, which act by converting the poison into the carbonate. Ringer § asserts, that the carbonate being but slightly soluble in the animal fluids, its action on the tissues is very weak, while in large doses it produces some nausea and vomiting; that zinc does not become fixed in the body, nor does it produce chronic affections, like lead or mercury. In fact, the almost universal testimony appears to point conclusively, also, to the innocuity of this compound.

It remains for us to consider the effects of the zinc which is contained in water in a soluble condition. It has been stated in a former part of this paper, that we are unable to say positively what salt or salts of zinc are present in such solutions. In some instances, however, it has been assumed, that the

chloride and the sulphate have been present. With equal reason, we might assume, in the case of many drinking-waters, the presence of nearly all the salts of zinc, the acetate, valerianate, iodide, etc. Admitting, then, that water which has been stored in reservoirs or drawn through pipes of galvanised iron always contains zinc in solution, in the form of one or more of its salts, the innocuity of these salts, in the quantities in which they occur, is attested by the experience and experiments of various distinguished observers to whom we have already referred. Vauquelin and Deyeux, Devaux and Dejaer, Orfila, Merat and Lens, Christison, Gaultier de Claubry, Chevallier, Tardieu, Bouchardat and Fonsagrives, Winsor, W. R. Nichols and others, while they admit the deleterious influences which may be occasioned by the soluble salts of zinc, when taken internally in sufficient quantity or for a long time, are unanimous in the recommendation of the use of zined iron for the storing and conveyance of water. This observation naturally suggests the inquiry, what quantity of the different salts, and how long a time, is required for the development of apparent injurious effects? It is impossible, of course, to decide these points absolutely. Approximative conclusions, however, are readily obtainable by reference to the statements and experience of reliable authorities.

Devaux and Dejaer,* in opposition to the conclusions arrived at by Vauquelin and Deyeux,* concluded, from a series of experiments made with Spanish prisoners, that the citrate and acetate of zinc, produced by the action of vegetable acids upon zinc culinary vessels, cannot exert any action upon the human system, in the dose in which they can be found in food and swallowed without being aware of their presence; that in a stronger dose they impart an intolerable flavour, which would constantly cause any aliment to be rejected in which they might chance to be found. Exceptions, however, were taken to the general application of the results of these experiments, by Orfila,* who is sustained by numerous eminent authorities,† on the ground that they were made upon persons of good constitution and in good health, and they were not tried as well with delicate subjects, whose nervous systems were extremely irritable. In the process of cooking, too, other ingredients take part in the energetic action upon these utensils, and in increasing the amount and variety of soluble salts of zinc contained in the food. Most of these authorities, however, assert, at the same time, or imply, that no danger is to be feared from the employment of zinc or zined material for the storage and conduction of drinking-water.

The sulphate and chloride are known to be the most active poisons of all the salts of zinc; but their harmless character, as they occur in drinking-water, may be shown by reference to experience in their administration as medicines. If this, then, is true of these salts, it will be apparent that objections to the use of galvanised iron pipes for the conduction of water, on account of the presence of the milder salts, are groundless.

The sulphate has been used for a long time in the practice of medicine. In small doses, from one-half to three or four grains, it has often been administered as a tonic and astringent. But it is observed that the system soon becomes habituated to its use, and in consequence of this fact it is always necessary to

* *Loc. cit.*

† See various articles and works cited in previous pages.

increase the dose gradually in order to obtain the desired effects. In this way, very large doses have been given. Babington* gave as much as thirty-six grains three times a day, without producing any ill effects. Another physician reports† that he has given forty grains, three times a day, for a long period, without any ill effects. Ordinarily, however, it acts as an immediate emetic in large doses. Christison,‡ in regard to the effects of frequent small doses, remarks that he has often given, medicinally, from three to six grains daily, for weeks, without observing any particular effect, except, in some persons, sickness when the larger doses were taken. He adds, that others have frequently made the same observation. In fact, it would seem that if the sulphate, which might occur in drinking-water, had any action upon the human system, it would be favourable, in the way of a tonic, rather than otherwise. As an argument, too, in support of the harmless nature of the very small doses which we have under consideration, mention may be made of the very general silence of authorities on the subject.

On the other hand, the acrid, corrosive nature of the chloride of zinc very naturally occasions a suspicion that even small amounts of it would prove injurious. But it has been administered internally, in small doses, for the relief of certain affections, when it has been considered to act as a slight tonic and stimulant. Pereira‡ observes that, taken in very small doses, no obvious effects are produced, except sometimes the amelioration of certain diseases. He states, further, that when applied externally, as a caustic, there is no danger of any constitutional disorder arising from the absorption of the poison, as is the case with the arsenical and mercurial caustics. Common testimony also establishes the fact that the system becomes habituated to the presence of this compound, so that doses of it require to be increased gradually in chronic affections; in this way, even twelve grains have been given daily without ill effects, though ordinarily one generally commences with a dose of about one-half a grain.

Oosterlen † states that, in small doses, it produces no obvious effects, being similar, in this respect, to the other soluble salts of zinc.

Van Hasselt‡ observes that the long-continued administration of two to four and more grains daily is reported to have given rise to affections simulating chronic mercurial poisoning, but makes no mention of ill effects from more minute doses.

Indeed, there seems to be no authority for the assumption that the chloride is injurious, even if it be allowed that the greater part, or the whole, of the zinc, which occurs in solution in water drawn through galvanised iron pipes, is in this form. Further, the fact must be borne in mind that the zinc salt or salts in this water are in an extremely dilute condition—usually but a small fraction of a grain of metallic zinc being detected in the gallon. Now, it has been estimated§ that a healthy adult man consumes a little over four and a half pounds of water daily, in food and drink, or a little less than four and a half pints (apothecaries'). If, then, a given water contained, in solution, one grain of zinc salts to the gallon, which would be absolutely exceptional, only

about one-half a grain would enter the stomach in twenty-four hours; and it has been shown that any of these salts may be taken in larger doses, three times daily, with slight, if any, effect upon the system.

Notwithstanding the prejudice existing in a few localities (which we have shown to be unsupported by the facts), against the use of zinc pipes, the general opinion is decidedly opposed to the idea of danger from their employment, and this fact is attested by the constantly increasing demand for such pipes. In Philadelphia alone, where there are five establishments for the manufacture of galvanised iron, about five million feet of pipe were sold during the year 1873 and sent to different parts of the country.

Inquiries addressed to the superintendents of the water-works of Salem, Beverly, and Cambridge, Massachusetts, and of Portsmouth, New Hampshire, where galvanised iron pipes have been used extensively for several years, have elicited replies, based upon the observation of the writers, the opinions of the water consumers and of reliable physicians and chemists whom they have consulted, to the effect that the use of these pipes is unattended with danger to health. The following extract, from the communication of Mr. D. H. Johnson, Jun., superintendent of the city water works in Salem, will serve to illustrate the general opinion expressed in the above and other communications received by the writer.

'It is only my province, as a practical man, to give you facts. We have, upon these works, 4,300 services inserted to the walls of buildings, containing 128,500 feet of galvanised iron pipes, or say twenty-four miles. There are as many more feet of pipes inside the walls of the houses, running (as is generally the case) across the cellars to the back part of the houses, and then up to the draw-faucets in the sinks and to tanks in the top of the buildings. In round numbers, it is safe to say, forty-eight miles.

'Our medical men in this city have been consulted during the past five years upon the subject, and they have failed to trace, even in a single instance, any disease arising from, or to find any evidence of injurious effects from drinking-water drawn through such pipes.'

In the extensive zinc and galvanised iron manufactures of Europe, practical experience and expert testimony* have demonstrated conclusively that the workmen suffer no deleterious effects which could be ascribed to the zinc to which they are exposed in various ways. The same is true of the galvanising works in this country. In reference to this point, communications have been received from the directors of large establishments in Philadelphia and Pittsburg, Pennsylvania, stating that 'the workmen employed are as stout, strong, healthy and able-bodied men as can be found in any of our iron mills,' and that none of them have ever been affected with any sickness which was attributed by themselves or physicians to the effects of the zinc to which they are constantly exposed. Some of them have been employed in these and in European manufactures for twenty years and more, without having experienced any ill effects, and still do a good day's work.

Many entertain a suspicion that the use of these pipes and tanks may be dangerous, in consequence

of the poisonous impurities which, it is said, the zinc coating may contain.

It is known that zinc ore contains many impurities. In the process of smelting, however, it is freed from these to a great extent, though not completely, and commercial zinc or spelter is never absolutely pure, but contains, generally, traces of sulphur, iron, and arsenic (Brande and Taylor). Other authorities also mention, in addition to the above, lead, tin, cadmium, and carbon. In the process of galvanising iron, again, these impurities become separated from the zinc to a still greater extent, so that the zinc coating contains but the merest trace of them. The essentials of this process have been given before. The zinc is placed in large vats, generally holding about twenty tons, and subjected to a heat of about 740° Fahr. This heat necessarily expels nearly the whole, if not all, of the remaining sulphur and arsenic which were not separated from the original ore by the primary smelting process. At the same time the contained lead, iron, cadmium, &c., are melted with the zinc, but are rapidly deposited at the bottom of the vat, in consequence of their greater specific gravity. These precipitated matters form a waste, called the 'dross,' which amounts, in each vat, to six or seven thousand pounds weekly, and is shown by analysis to be composed as follows:—

| | | | | | | | | |
|-------------------------|---|---|---|---|---|---|---|--------|
| Zinc | . | . | . | . | . | . | . | 94.88 |
| Iron | . | . | . | . | . | . | . | 3.55 |
| Tin | . | . | . | . | . | . | . | 1.00 |
| Lead | . | . | . | . | . | . | . | .30 |
| Balance of other metals | . | . | . | . | . | . | . | .27 |
| | | | | | | | | 100.00 |

The specific gravity of this dross is 7.06, while that of ingot zinc is 6.86. Now, as all iron is zincd from the top of the vat, it does not come into contact with these impurities, which are at the bottom, and hence the zinc coating can contain but mere traces, if any, of them; at all events, not enough to be the occasion of any deleterious effects upon the human system.

Most of the galvanising in this country is done with the German spelter, which is preferred by manufacturers to the American article, notwithstanding its increased cost, 'because it is thought to make the best finish, running brighter and thinner on the iron than the product of our native mines.' Now this German zinc contains usually, according to numerous analyses, but a fraction of one per cent. of lead, the only ingredient which can possibly be the occasion of suspicion. As the greater portion of this minute quantity is precipitated to the bottom of the vats, the still more minute quantity which is present in the zincd product, evidently is unworthy of attention in the way of its endangering health.*

To recapitulate: it is proved theoretically, experimentally, and practically, that zinc is acted upon by ordinary drinking-water; that water, allowed to stand in reservoirs, or drawn through pipes of zincd or galvanised iron, usually contains an appreciable amount of zinc, more or less, according to various influences; that the zinc, contained in the water, is in the form of undissolved oxide and carbonate and of dissolved salts, the exact nature of the latter not being known; that probably under no circumstances is the oxide or the carbonate an active or gradual

poison, much less in the amounts in which they can occur under the conditions mentioned; that, at least with water fit for drinking purposes in other respects, the contained zinc salts in solution do not exert any deleterious effects upon the human system; finally, that, even if all the zinc in solution were in the form of the chloride, which is known to be the most active poison of the zinc salts, the amount would still be insufficient to endanger health.

OBSTETRICS AND GYNÆCOLOGY.

ZWEIFEL ON THE INFLUENCE OF INHALATION OF CHLOROFORM ON THE FÆTUS DURING DELIVERY.—Dr. Zweifel (*Berliner Klinische Wochenschrift*, May 25, 1874), observing that children born when chloroform had been administered to the mother were frequently jaundiced, was induced to make some investigation to see whether the anæsthetic could be traced to the child, which might explain the excess of jaundiced children when the mothers were chloroformed.

He first searched for chloroform in the placenta. This was carefully washed and then cut up into small pieces and placed into a retort, and distilled by means of the sand-bath. There was a perceptible odour of the vapour; but to be more sure he tested for it, and in every case a trace was found. He then proceeded to examine the urine of children whose mothers had been anæsthetised, and without exception found chloroform.

In one case, whilst the anæsthetic was being given to the mother, the fœtal pulse suddenly became less frequent and the sounds scarcely audible. Delivery had to be hastened to rescue the child.

From the experiments made he came to the conclusion that chloroform inhaled by the mother passes to the child, and it is anæsthetised with the mother. As narcotism is contraindicated in children, Dr. Zweifel intends prosecuting his investigations to see to what extent it can be given without injury to the child.

W. C. GRIGG, M.D.

GILLESPIE ON CAUTERISATION OF THE UTERUS. Dr. Wm. A. Gillespie, of Louisa Court House, Virginia, writes to the *Boston Medical and Surgical Journal* as follows. 'Much has been said about the difficulties and different plans of cauterising the internal surface of the cervix uteri and of the body of the uterus, and of the dangers of injecting any liquid caustic preparation into it. I am, therefore, prepared to give a simple, easy, and efficient plan for cauterising the canal of the cervix, and even the cavity of the body of the uterus. I have practised it repeatedly, in a large number of cases, with the happiest results.

'Take an ordinary sponge-tent and coat it with beeswax, and then roll it for some time with a knife in powdered nitrate of silver, which will sink into, and adhere to, the wax. Then through a suitable speculum carry the prepared tent through a cervix, and if desirable, to the fundus, and let it remain twenty-four hours. No remedy in my hand has done more good in as short a time, in chronic inflammation, engorgement, enlargement, or ulceration of the os and cervix uteri, and I have never known any unpleasant results from it.'

* Compare Report of State Board of Health of Massachusetts for 1871, p. 42, as to amounts of lead required to produce injurious effects.

MISCELLANY.

A COMMITTEE on Medical Statistics is about to meet in Berlin under the Presidency of Herr Bitter.

SMALL-POX IN STOCKHOLM.—During the week ending June 5, there were 122 cases of small-pox in Stockholm, with 28 deaths. From the outbreak of the epidemic, the number of cases was 4,021, and of deaths, 857.

It is stated that Professor Piazzi Smith, who has an extraordinary affection for the great pyramid of Egypt, has resigned his fellowship in the Royal Society because that body refuses to receive a paper in which he claims to have proved that the said pyramid was built by Melchisedec under Divine inspiration.

THE COMMERCIAL VALUE OF ABSTRACT SCIENCE.—Though the possibility of producing alizarine by artificial means was demonstrated only in 1868, the production in Germany during 1873 reached the figure of 1,100 tons, with a value of 600,000*l.*; and it is announced that one single establishment of Germany, where there are ten or twelve in all, is preparing for a production of 5,000 tons of alizarine paste per year.

THE HORSE AND HIS RIDER.—M. Perret, a French pharmaceutical chemist, has discovered a very simple and economical method of saving horses, particularly when they are not in motion, from being tormented by flies. It consists in merely rubbing them with a little concentrated oil of laurel, which is extremely disliked by the flies. The oil should be specially applied to the parts where the flies usually settle. With about three pennyworth of this oil a horse can be anointed for three days. There is not the slightest danger in using it, and, indeed, its slightly stimulating action is beneficial to horses, and keeps their coat in good order. This expedient may also be usefully replaced by a solution of 60 grammes of assafoetida mixed with one glass of vinegar and two of water. The strong odour of the assafoetida drives away the flies, and if horses be well washed with this, not a fly will settle on them. No apprehension need be felt in using the assafoetida, which has no deleterious properties.

A NEW SUBMARINE THERMOMETER.—Dr. Carpenter lately placed before the Royal Society a new meteorological instrument constructed for him by Negretti and Zambra. This instrument enables the true temperature of the sea at any given depth to be ascertained. Up to the present time there has been no certainty of an exact determination of the temperature at the actual depth, by sinking the thermometer in submarine soundings; because the registering instrument was subject to the influence of the layers of water through which it passed both in descending and in ascending. The new thermometer avoids this uncertainty. It is composed of an ordinary glass thermometer with a round bulb, which bends back in the form of a siphon, and has a small reservoir of mercury at the lower end of the retroverted limb. A very simple mechanical arrangement gives this apparatus a tilting movement, which completely inverts it when it reaches the precise depth at which it is desired to observe the temperature. By a rotatory movement round an axis, the bulb of the thermometer is raised and then sunk again, and the mercury which has then passed from the limb bearing the reservoir, into that which corresponds to the scale of degrees, remains there and indicates the exact temperature of the medium at the moment of rotation. A clock-work movement analogous to that of an alarm, applied to the rotatory mechanism, allows it to be used both on land or in a balloon, at any hour of the night or day, regulated in advance by the alarm. The instrument thus modified indicates the temperature of the medium, into which the thermometer was plunged at the moment of rotation. By the aid of this movement, the instrument described can be as easily applied to terrestrial as to submarine observations.

THE fourth International Pharmaceutical Congress will be held in St. Petersburg in August next, commencing on the 1st (13th) of the month.

THE new Pathological and Anatomical Institute in Padua was opened on May 20, in the presence of a large assemblage. An address was delivered on the occasion by Professor Brunetti; and busts of Morgagni, Rokitanaky, and Virchow were unveiled. Padua, it will be remembered, was the scene of Morgagni's teaching.

THE LIFFEY AND THE IRISH PUBLIC HEALTH BILL. The abominable and poisonous stench with which the Liffey infects the air of Dublin may possibly be borne with a nearer approach to resignation, if it may be reasonably hoped that the progress of the Public Health Bill (Ireland) in the House of Commons will not be checked by the obstructions which the Corporation of Dublin are interposing to its passage. The poisonous state of that gigantic sewer—for as it runs through Dublin the Liffey is nothing else than an open ditch, of which the water is thick with putrefying sewage—is a standing example of the manner in which the Dublin Corporation understands and carries out its sanitary duties. For years it has delayed, and jobbed, and quarrelled over the purification of the Liffey, and it wakes up to find that while it has been delaying, values have been rising. To purify the Liffey now will cost the ratepayers half as much again as it would have done ten years ago. All the sanitary affairs of Dublin have been managed in the same way. Three years ago, when the *British Medical Journal* sent over a commissioner of inquiry, he reported that fever patients were carried about the city in costermongers' carts, that the so-called disinfecting chamber was nothing else than a smoke-cupboard, and that the whole sanitary administration was a mockery and a sham. The Dublin journals followed suit, and a voluntary sanitary association has been formed, which has forced the Dublin Corporation into some pretence of activity; but a very pitiful and hollow pretence. It is characteristic of their whole spirit in sanitary matters, that their main ground of opposition to the Public Health Bill now is, that it does not give them enough of patronage in the posts to be created.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 1*7s.* 4*d.*; free by post, 1*9s.* 6*d.*

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2*s.* 6*d.* each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & CO., London; and through their Agents—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 1*9s.* 6*d.* Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1*s.* 6*d.* each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & CO.—Calcutta: THACKER, SPINK & CO.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & CO.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & CO., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JULY 1, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

LECTURE UPON THE GENERAL THERAPEUTICS OF THE NERVOUS SYSTEM. BY E. C. SEGUIN, M.D.*

Gentlemen,—I have thought that the last hour of your survey of nervous diseases could not be better spent than in a rapid review of certain principles of therapeutics, and in a partial study of the remedial agents classified as much as possible in accordance with these principles. In offering you the following classification, I wish to warn you that it has little in common with the therapeutic propositions which you will find in text-books, whether upon the practice of medicine or upon diseases of the nervous system. Inasmuch as the ground to be gone over is large, you will pardon me if I restrict myself to short practical remarks upon the various heads of the lecture.

The following is the classification which I have long had in my mind, and which I now submit to you:

- | | | |
|---|--|------------------------------|
| A—Agents which affect the blood-supply of nervous system. | 1. Agents which increase the blood-supply. | |
| | 2. Agents which diminish the blood-supply. | |
| B—Agents which affect the substance of nervous system. | 1. Agents which increase action of | a. brain. b. spinal cord. |
| | 2. Agents which diminish action of | a. brain. b. spinal cord. |
| C—Restoratives and Tonics. | | |
| D—Counterirritants. | | |
| E—Electricity. | | |
| F—Hygienic means. | | |

CLASS A.

Means which affect the Blood-supply.

The indication for affecting the blood-supply of a nerve-centre is sometimes a perfectly correct and logical one. In practice, we have a certain class of cases in which the symptoms are due to hyperæmia of nerve-centres, and also a certain class in which the symptoms are due to anæmia of nerve-centres. The vital question is to determine whether the hyperæmia or anæmia be primary or secondary.

Few questions in pathology are of more importance than this, and few have caused such prolonged discussions. This is not the place to examine this matter, and I must limit myself to stating the conclusions to which experience has led me. I believe that true primary hyperæmia of the brain or spinal cord is a very rare affection, infinitely rarer than the teaching of books would lead us to suppose. In many so-called cases of cerebral congestion there is, I believe, no hyperæmia, but only malnutrition, which may be attended by a secondary and passive congestion. In all such cases, the leading indication

is not to deprive the nervous centre of blood. The effects of anæmia are better known and more commonly observed; and it is an instructive fact to recollect that what we to-day consider as typical of anæmia (epileptic loss of consciousness) was not many years ago looked upon as typical of hyperæmia. In brief, I believe that the indication to diminish the amount of blood circulating in the brain (and spinal cord) is very rarely presented to us practitioners, and that the contrary indication is much more commonly encountered.

The first class of means is subdivided into two subclasses.

1. Means which increase the blood-supply.

This subclass may be still further subdivided as follows:

- a. Decubitus, or posture.
 - b. Compression of arteries of limbs.
 - c. Stimulants.
 - d. Agents paralyzing the vaso-motor nerves.
 - e. Measures which act by increasing the activity of the nervous centres.
- a. The amount of blood in the spinal cord can be materially increased by placing the patient upon his back. The amount of blood in the brain can be materially increased by elevating the legs and arms. In syncope, therefore, and in all cases where we may suppose that anæmia of the brain is present, the first thing to be done is to place the patient upon his back, and we may, besides, elevate the limbs and trunk. Anæmic patients, who have no positive disease, but who at times feel weak and faint, or suffer from attacks of vertigo, should also have recourse to this means.

b. Compression of the arteries of the limbs is a very important and powerful means. This should be done by tourniquets, as ordinary bands alone will not arrest the circulation carried on through the arteries, but will prevent the return of blood to the body. This procedure is one which is rarely resorted to, and I would recommend its execution only in extreme cases of cerebral anæmia, as a means next to transfusion. The tourniquets should be applied not simultaneously, in order that you may study the reaction of the heart. In the days when epileptic seizures were regarded as due to cerebral hyperæmia, compression of the carotids was advised and done to cut short the paroxysms. Insensibility can in this manner be produced in the healthy individual. In epileptics the results obtained were not satisfactory, and the measure is one which we now condemn as unphysiological. Besides, in pressing upon the carotid we act upon the vagi, and influence the heart in that way.

c. Of the stimulants, alcohol is the best. Preparations of ammonia are employed, but they are less efficient than alcohol. The dose of alcohol in cases of anæmia of the nervous centres is to be gauged only by the degree of reaction observed. In the drowsiness and exhaustion which result from prolonged exposure to cold with or without over-exertion, in cases of loss of blood, brandy will be tolerated in enormous quantities, and the subject saved. In general terms, food is to be regarded as a stimulant, for the general circulation is made more active by taking it. Probably many of you have had an afternoon headache magically cured by dinner.

d. Paralyzing the vaso-motor nerves, by producing enlargement of the arteries, is productive of hyperæmia in the arterial district to which the nerves are distributed. This proposition is demonstrable by

* From *The New York Medical Record*.

experiment upon animals. If we cut the sympathetic nerve in the neck (as was done by Pourfour du Petit in 1712), we obtain a dilatation of all the arteries of the superficial parts of the head, and of all parts of the face, together with contraction of the pupil. As signs of hyperæmia, we observe increased size and pulsation of arteries, redness, increased heat, increased secretory action. If we excise the superior cervical ganglion of the sympathetic, we produce hyperæmia of the brain itself. In medicine, we cannot resort to this radical means of paralysing the vaso-motor nerves. Of means to be used for this purpose, the most effectual is inhalation of the nitrite of amyl. The proper dose is from two to five drops. If the remedy is to be administered by the medical attendant, it needs no preparation; five to ten drops may be poured upon a cloth or handkerchief, and a part or the whole of the quantity allowed to enter the patient's nostrils. In many cases the physician is away during the illness or seizure requiring the use of nitrite of amyl, and the nurse may give it safely, diluted in alcohol, in such a way that a teaspoonful shall hold the proper dose. The effects of nitrite of amyl, apparent in a few seconds, consist in hyperæmia of the head and face, of increased action of the heart, and of redness and heat in the remainder of the body sometimes. From the condition of the face and the external parts of the head, and from the sensation of fulness in the eyes and within the head, associated often with giddiness, we infer that there is hyperæmia within the cranium as well as without. One indication for the use of this remedy we find in the condition present at the commencement of an epileptic convulsion. In the very earliest stage, during the occurrence of the aura, or the period preceding the aura, which is recognised in some patients, is the proper time to resort to this remedy. If used then, or at the moment the spasm of the vaso-motor nerves commences, indicated by the first signs of failure of consciousness, in many cases the attack can be aborted; in others diminished in severity. Nitrite of amyl has also been used with success in angina pectoris, in asthma, and in various spasmodic affections, involving muscular or vascular parts.

Chloroform has been used in the same manner, but its mode of operation is unknown, and it is much less effectual.

Another means is by overstimulating the sympathetic nerves, but this cannot be employed with any great degree of certainty. This is more theoretically than otherwise correct (*vide infra*, subclass 2, e).

e. The means which produce functional hyperæmia are exceedingly numerous, embracing as it does all those agents which increase the activity of the nervous centres. Hyperæmia of the nervous system occurs as the result of functional activity in the same manner as it is developed in the various organs of the body as the result of the same cause; such as the congestion present in the stomach and intestines and liver, during digestion, etc. In this connection it is well to remember that it has been shown that increased temperature about the head is developed during exercise of the mental faculties, or by the operation of emotion.

The medicines referred to will be found in class B, subclass 1.

2. The second subclass of A embraces all the means employed to diminish the amount of blood circulating in the nervous centres.

a. Venesection.

b. Decubitus.

c. Compression of veins of the limbs.

d. Cold.

e. Those means which stimulate the vaso-motor nerves.

f. Means which diminish the activity of the nervous centres.

a. There can be no doubt that blood-letting, if sufficiently large, will produce cerebral anæmia, for, although physiologists still believe that the quantity of contents of the cranium is invariable, yet they to-day admit that the amount of intracranial blood may be reduced; serum taking its place about the vessels and in the subarachnoid space. I need hardly tell you that bleeding is out of fashion, and that we nowadays never use it. I would, however, say that with sufficient symptoms of sudden and violent cerebral hyperæmia occurring in a subject full-blooded enough not to be injured by the loss, I should bleed without hesitation, by a large opening, and to impending syncope.

It is perhaps right for me to speak here of leeches and wet cups, in order to express my belief that these agents do not relieve hyperæmia of deeply placed organs so much by withdrawing blood, as by irritating nerves, and thus acting upon the vaso-motor nerves of the affected parts. These means should therefore be placed in class D, with counterirritants.

b. If the brain is the nervous centre to be affected, the *decubitus* should be with the head raised; or the patient should be placed in a chair with his legs and arms in a dependent position. This latter posture is useful in certain cases (rare, I believe) of insomnia dependent upon true, primary cerebral hyperæmia.

In cases of spinal congestion, myelitis, or any affection of the spinal cord attended by congestion, place the patient upon his face. Relief may be secured by permitting the patient to occasionally lie upon the side, but lying upon the back should be almost entirely forbidden.

c. Compression of the veins of the limbs may be effected by means of ligatures. Formerly employed in convulsive affections, it has now fallen into almost complete disuse.

d. Cold, when used in a proper manner, undoubtedly has the power of diminishing the amount of blood in a part deeper than the skin. It must, however, be applied continuously if any benefit would be derived. In the treatment of meningitis and all affections in which there is present hyperæmia, either primary or secondary, within the cranium, ice should be placed upon the head and at its base for considerable periods of time, carefully watching the effects in order to remove it at once if there is evidence that too much depression is being produced. The same means may be used with benefit in intraspinal inflammation and congestions.

Cold is also applied to the back of the neck and upon the spinal column with the object of acting, through the spinal cord, upon the vaso-motor nerves going to distant organs.

A word as to the means of using cold. You will hear Chapman's India-rubber bags highly recommended, but I suspect that their cleanliness and ease of application are what have caused their fame. It is best to apply the ice in block immediately to the skin, well guarded by cloths to catch the drippings; or pounded ice (with or without salt), enclosed in a cloth or bladder, may be used; or, lastly, the ether spray-douche may be employed.

e. The vaso-motor nerves may be directly stimulated by galvanism, causing contraction of the arteries supplied by these nerves, and consequently anæmia of the parts to which these arteries go. This may be experimentally demonstrated, for the face, by galvanising the sympathetic in the neck; for the fundus of the eye and the brain, by localising the action of the current upon the superior cervical ganglion. The positive pole should be applied under the ear, in front of the mastoid process (small electrode), the other electrode be placed upon the fifth cervical vertebra; the current of from four to eight Stöhrer's cells, allowed to pass for one to two minutes. Evidence of spasm of the cerebral arteries is obtained in the shape of vertigo developed at the moment of closing and opening the circuit. The vessels of the fundus of the eye have been seen to grow smaller under this application. Anæmia of a part of the brain is no doubt the inevitable immediate result of thus irritating the superior cervical ganglion, but a law of physiology stands in the way of our accepting this as a means to be used to meet the indication of diminishing the supply of blood. The law I refer to is that of neverfailing relaxation after spasm, of exhaustion after stimulation. This law leads me to believe that after the primary cerebral anæmia produced as above described, there is a consequent, equally inevitable relaxation of blood-vessels and hyperæmia produced. This is how I would justify the placing of this means, galvanisation of vaso-motors, among those which increase the amount of blood in the brain (*vide supra*, subclass 1, d).

Among medicinal agents, I know few which will stimulate the vaso-motor nerves, which are not medicines that should be embraced in another class. One exception, perhaps, is ergot. Some recent observations seem to indicate that ergot diminishes the amount of blood circulating in the spinal cord and in many other tissues. It has been demonstrated that belladonna in small doses will accomplish the same thing. These two remedies, therefore, are quite generally used in the treatment of congestions and inflammations affecting the nervous centres. We are indebted to Dr. Brown-Séquard for their introduction into practice upon correct indications.

f. Diminution of the activity of the nervous centres may be brought about by mental and physical rest. By mental rest I understand, not inactivity, but a cessation of the strain, intellectual or emotional, which has acted upon the patient. The merchant or professional man should diminish or cease altogether his work, whether in the way of actual labour or responsibility; he should resort to other occupations and to amusement. On the contrary, the emotional girl, or the insane subject, should be given work, physical if possible, in order to withdraw the attention from the contemplation of delusive sensual or pure emotional subjective creations. The operations of grief, of misery, of concentration in a diseased self, should be remedied by a variety of means (including amusements) which will suggest themselves to you. At all events, please remember that mental rest is not synonymous with inertia or idleness.

Physical rest is of great utility, and has been employed in locomotor ataxia with especial benefit.

Various remedies may be used for the purpose of diminishing the activity of the nervous centres, and these will be referred to in subclass 2 of the next class, B.

(To be continued.)

HITZIG ON EXPERIMENTS ON THE BRAIN.*

In this volume Hitzig reprints the first paper on the electrical excitability of the brain, which he published in conjunction with Fritsch in Reichart and Du Bois-Reymond's *Archiv* for 1870 (Heft 3), as well as a second by himself on the same subject in a subsequent number of the same *Archiv* for 1873 (Heft 3 and 4, published in January, 1874.) Besides these, there are other papers containing new researches relating to the physiology of the nervous system. The third paper in the volume is entitled 'Kritische und Experimentelle Untersuchungen zur Physiologie des Grosshirns, im Anschluss an die Untersuchungen des Herrn Professor D. Ferrier in London.' This paper is devoted to an examination of the researches on cerebral physiology and pathology which were published by the reporter in the *West Riding Lunatic Asylum Medical Reports*, vol. iii. 1873, which appeared in the beginning of August of that year, and of which an abstract had been published in the *British Medical Journal* for April 26, 1873.

Hitzig complains in a spirit of great bitterness of the relatively greater amount of credit which has been accorded to the reporter than to him; claiming for himself the discovery and clear enunciation of all the main facts of the research so long as three years ago, and charging the reporter with having given too little credit to his labours, and published as new discoveries what he had already ascertained and described. He speaks of the reporter's experiments as being merely a repetition of his own, and as adding little new to the facts already made out by him. He likewise contests many of the statements made by the reporter, and endeavours to show that the method of experiment followed by him is full of fallacies, and that the conclusions founded on it are untrustworthy as compared with those obtained by the method of galvanic excitation which he himself follows. The applications of the facts of experiments to the elucidation of obscure points in the physiology and pathology of the brain made by the reporter, he regards as unwarranted and hypothetical, and in general endeavours to depreciate the value of the reporter's contributions to cerebral physiology, as compared with the much greater accuracy and definiteness of his own.

Much of the animus in which Hitzig writes may be excused by the feeling of disappointment naturally arising in the mind of one who, having in his hands a potent instrument of research, makes but a limited application of it, and fails to push the facts of his discovery to their logical termination.

The merit of the discovery of the method of exciting the functional activity of the brain by electrical stimulation belongs to Fritsch and Hitzig, and this the reporter has distinctly recognised and willingly accords to them. But though a new method potentially contains the germ of all that grows out of its application, the discoverer of the method can hardly lay claim to all the facts and their applications to which it may lead in the hands of another. Fully three years had intervened between the publication of Fritsch and Hitzig's results, and the appearance in full of the reporter's first paper; and before Hitzig had added to the facts already published by him and Fritsch in 1870, the reporter had communicated to

* *Untersuchungen über das Gehirn.* Von Dr. Eduard Hitzig. Berlin, 1874, p. 276.

the British Association in September 1873, the facts and conclusions founded on them of an extensive series of experiments not only on dogs, but on cats, rabbits, guinea-pigs, jackals, numerous monkeys, and also on birds, frogs and fishes. Abstracts, of an imperfect nature it is true, of the reporter's paper at the British Association, appeared in the *Times* of September 22 (from which Hitzig quotes), as well as in the other papers and medical journals of about the same date. The results of these later experiments, in all essential particulars the same, but with numerous additions, were embodied in detail in a paper on 'The Localisation of Function in the Brain,' presented to the Royal Society on February 20, 1874, of which a short abstract of the main facts has been published in the *Proceedings of the Royal Society*, no. 151, 1874.

In the second paper, which, however, Hitzig has not seen in full, all the facts of Hitzig's late experiments on other animals have already been anticipated, and much more.

Hitzig's second paper was not published till January, 1874, and in this he has added but little to the facts narrated in the paper he wrote in conjunction with Fritsch, already alluded to. The reporter's allusions to Hitzig's researches are of necessity to be considered as referring to the first, which alone he could have seen, seeing the second paper did not appear till some months subsequently to the announcement of the reporter's results. Hitzig's experiments were confined to a very imperfect exploration of the hemispheres in dogs, and it can hardly be said that the reporter's research is merely a repetition of Hitzig's, when in the first paper not only had the hemispheres of dogs been almost completely investigated, but also those of cats and rabbits, along with the corpora striata, the optic thalami, the corpora quadrigemina, and in rabbits the cerebellum. Without alluding to the more complete series of experiments described at the British Association, and embodied in the paper presented by the reporter to the Royal Society, it will be sufficient to examine Hitzig's claims and charges by reference to his first paper, which was the only one which had appeared when the reporter had published his in the *West Riding Reports*. In this the reporter thus alludes to Fritsch and Hitzig's researches: 'We owe to Fritsch and Hitzig a demonstration of the fact that the brain is not, as has been generally stated, unsusceptible to every kind of irritation. They showed that irritation of the anterior parts of the brain by a constant current gave rise to certain movements on the opposite side of the body, and they attempted to localise in certain definite points the centres for such muscular movements. Their researches in this direction were not carried very far, nor do they, I think, clearly define the nature and signification of the results at which they arrived' (p. 32).

The exact extent of Fritsch and Hitzig's research will be best described in their own words. (The references are to a woodcut of the brain of a dog on which the five points—and they are only points—are marked).

'The centre for the neck-muscles (Δ Fig. 1) lies in the lateral part of the præfrontal gyrus, at the point where the surface of this convolution abruptly descends. The outermost end of the post-frontal gyrus contains (*birgt*) in the neighbourhood of the lateral end of the frontal fissure (+ Fig. 1) the centre for the extensors and adductors of the fore-limb. Somewhat behind the same and nearer the coronal fissure

(+ Fig. 1) lie the ruling centres (*vorstehenden Centralgebiete*) of the flexion and rotation of the limb. The centre for the hind-leg ($\#$ Fig. 1) is also found in the postfrontal gyrus, but nearer the middle line than that of the fore-leg, and somewhat farther back. The facial (\odot Fig. 1) is innervated from the middle part of the supersylvian gyrus. This region generally has an extension of over 0.5 centimètre, and stretches from the principal bend (*Hauptknickung*) above the Sylvian fissure before and behind.

'We must add that we did not always succeed in setting the neck-muscles in action from the first-mentioned point. The muscles of the back, tail, and abdomen we have often enough excited to contraction from points lying between those marked, but no circumscribed point from which they could be isolated irritated could be satisfactorily determined. The whole of the convexity lying behind the facial centre we found absolutely unexcitable, even with altogether disproportionate intensity of current,' (pp. 13-14).

This forms the sum and substance of all that Fritsch and Hitzig made out in their research. Whether they had observed the definiteness and purposive character of the actions which the animal is made to perform when these centres are stimulated or not, it cannot be said that they have clearly expressed the fact in their description. What is meant by the 'facial centre,'—what is the nature of the action which it excites, they nowhere describe. The facial nerve innervates numerous muscles, but they leave it entirely vague as to whether the actions they observed can or cannot be compared with the definite results described by the reporter. A centre for the hind leg explains nothing of the character of the action which stimulation induces. So also 'centres for the extensors, flexors, and rotators of the fore-limb,' merely vaguely indicate that which is the real and essential nature of the acts which the animal is made to perform. What may have been the result of stimulation of the 'centre for the neck-muscles' is nowhere indicated. The definite and purposive character of the actions excited, and their evident relation to the habits and intelligence of the animal, are not brought out; and the grounds of comparison are so indefinite that the reporter could scarcely bring them into exact relation with the results of his own method. He is inclined to think that the method followed by Hitzig was not the best calculated to express the real meaning and extent of the muscular contractions they observed.

As regards the 'neck-centre' the reporter has differentiated different points for definite actions, and determined the respective effects on the eyelids, eyeballs, and pupils. Such a compound result can hardly be generalised into a 'neck-centre.' The individual movements of the fore and hind limbs and paws are definitely described by the reporter, and the extent of the respective areas marked off. What Fritsch and Hitzig call the 'facial centre' is only a minute point in an extensively differentiated area of complex movements. All the rest of the brain giving the definite results described in the reporter's paper is absolutely unexplored.

Thus far in proof of their 'not having carried their researches very far.' What interpretations these authors put upon the results of their experiments may be gathered from the following, in which it will be seen that they come to a view entirely different from that which the reporter holds, and one which he regards as radically erroneous. Fritsch and Hitzig, after

discussing the various possibilities as to the relation of these centres to the 'will' and '*Seele*,' come to the conclusion that the only method of 'experimentally solving the question as to the signification of the individual parts of the cortex, is the extirpation of circumscribed and accurately ascertained parts of the same' (p. 28).

In pursuance of this, they performed extirpative experiments of certain centres in the brain of dogs.

The following words express their views, founded on these and their other experiments. 'Both the animals experimented on, had, after the extirpation of a part of the by us so-called centre for the fore limb, only partially lost the power of moving it, and probably sensibility was not at all affected. But they had clearly only an imperfect consciousness of the condition of this limb, the power to form a complete conception (*vollkommene Vorstellungen*) of the same was lost; they suffered therefore from a symptom, which in a very similar manner occurs in a form of the disease tabes, only that here there was no lesion of the sensory tract. More nearly to indicate this condition, it might be thus expressed:—there remained still some motor conduction from the mind (*Seele*) to the muscle, while in the conduction from the muscle to the mind, an interruption existed somewhere. Possibly this interruption hit the end-station of the hypothetical tract for the muscular sense (*Muskelsinn*); at all events it had its seat at a position in the centre destroyed by us' ('Mögllicherweise betraf diese Unterbrechung die Endstation der hypothetischen Bahn für den Muskelsinn, jedenfalls hatte sie aber ihren Sitz an Stelle des von uns verletzten Centrums,') p. 30.

Whatever interpretation Hitzig may have subsequently put on his experiments, the reporter thinks that by these words they clearly gave it to be understood that they regarded the motor centres as centres of the muscular sense. Having performed similar experiments, the reporter came to a totally different conclusion. He regarded the same centres as the centres of voluntary motion, differentiated above the lower co-ordinating basal and spinal ganglia, and as forming the motor substrata of mind.

From the foregoing analysis of Fritsch and Hitzig's labours, the reporter thinks he has not done great injustice to them by characterising their research as imperfect. And he might have said that not only had they not clearly defined the nature of the results they had before them, but had, in his opinion, absolutely misinterpreted them.

The reporter willingly admits the great service done to physiology by Fritsch and Hitzig in inaugurating a new method of exploring the functions of the brain, and exploding notions which had retarded investigations in this direction, and if he apparently undervalued them by not comparing in every instance his own with their results, it is to be ascribed in great measure to the indefiniteness of their statements. The reporter was likewise following a method which Fritsch and Hitzig regarded as unsuitable for the purpose. In some minor points the reporter has omitted in his first paper to indicate the coincidence of his own observations with those of Fritsch and Hitzig, omissions which he much regrets, on account of the construction which Hitzig puts upon them. He freely allows that they had noted the sensitiveness of the dura mater, and some of the conditions of excitability of the hemispheres. And in reference to the artificial production of epilepsy, he admits that Fritsch and Hitzig observed

epileptic convulsions in the case of two dogs which they were experimenting on. But after noting the facts, they make all their comments thereon in the following words: 'It might be said in objection that the dogs had been previously epileptic. The one dog had, however, been already kept by the same master for six years without having suffered from convulsions. The antecedents of the other remained unknown,' p. 17. With these words the whole subject is dismissed, and no attempt is made to explain the facts, or bring them into relation with the motor centres of the brain or the facts of pathology. It is one thing to state an isolated fact, and another to state it in its various relations and bearings. Fritsch and Hitzig have given no evidence of having appreciated the significance of the facts which lay before them.

Thus far the reporter has considered Hitzig's claims and criticisms in the light of the first papers published by him and the reporter respectively. Before Hitzig had materially added to his first results, the reporter had developed and greatly extended his researches, and announced them publicly at the British Association in September last year. Hitzig's later experiments are made the basis of his criticisms on the results, in some respects imperfect, contained in the reporter's first paper. This is so far excusable, inasmuch as the full details of the reporter's subsequent experiments have not yet been printed. But Hitzig will there find that the reporter has not only confirmed in all essential particulars his former results, but has explained in the light of new experiments the signification in regard to the localisation of sensory centres of many of the external phenomena which result from stimulation of the hemispheres. Hitzig, even in his most recent experiments, fails to add anything new to the facts already detailed in the reporter's first paper, and has not succeeded in localising function to the same extent as he has done, and apparently has no conception of the possibility of localising centres of sensation in what he regards as 'unexcitable' regions. Hitzig has repeated the reporter's experiments on dogs and cats, and he gives a minute analysis of the facts as compared with those related by the reporter. It is impossible without figures to criticise the points of agreement and difference. This must be reserved for another place.

In the main, as far as relates to positive results, Hitzig has discovered nothing new, and does not always succeed in obtaining the results narrated by the reporter. With a curious inconsistency, Hitzig accepts the results in so far as they agree with those obtained by his own method of galvanic excitation, but when he fails to obtain others in which the reporter has succeeded, he invariably denounces as untrustworthy the method of faradisation, and attributes the results to conduction from over-intense currents, reflex action, and the like. The reporter did not experiment with total disregard of such contingencies, and the results he describes are not haphazard, but definite and capable of repeated demonstration. The more rational course would be for Hitzig to adopt a method which succeeds when his own fails, a method which has in the reporter's hands demonstrated the localisation of function in the brain to an extent far beyond that attained by Hitzig. With respect to the conclusions which the reporter has founded on his experiments, which, according to Hitzig were undertaken 'entirely without the necessary physical training, without self-criticism (*Selbstkritik*), without consideration of

foreign not disputed statements,' (p. 112) his critic thus sums up his opinion. 'In short, Ferrier has used these experiments, which with one stroke were to unveil the secrets of every individual province of the brain, to draw the widest conclusions in reference to the pathology of the nervous system, in addition to their bearings on physiology. We went on the opposite principle, with the conviction that the conclusions are easy to draw if only the facts are well substantiated. The reader will be able to judge by which method the subject is more advanced. The results of his hitherto researches will hardly in many respects recall the wish that Ferrier's "ingenium," should once again come to the aid of our imperfect understanding (*mangelhaften Verständnisse*),' p. 111. Whether 'ex pede Herculem' was scorned by Hitzig's 'ingenium' or beyond his 'mangelhaftes Verständniss,' the reporter will not presume to judge; but he is of opinion that Hitzig will yet require to show much better cause than he has done for invalidating the trustworthiness of the facts which the reporter has related, and the applications which he has made of them.

D. FERRIER, M.D.

PATHOLOGY.

NEUMANN AND OTHERS ON THE PATHOLOGY OF MALIGNANT SMALL-POX.—The following is an abstract of a debate a few months ago in the Vienna Society of Physicians. Dr. Neumann read a paper in which he detailed the morbid anatomy of ten cases of 'purpura variolosa.' In three of them he found hæmorrhage in the perineurium of the spinal ganglia of the lumbar nerves; in a fourth there were opacities of the pia mater and arachnoid in the same region, with a nuclear inflammatory exudation on the corresponding part of the dura mater; and, in a fifth, extravasations of blood and granular opacities between the lumbar arachnoid and pia mater. In a sixth case, that of a young woman who died on the ninth day of the disease, there was hæmorrhage in the sheath of the roots of the lumbar nerves. On these facts Dr. Neumann propounded the theory (1) that 'the pains in the back' of malignant variola are due to implication of the posterior roots of the lumbar nerves in hæmorrhage; and (2) that the ecchymoses characteristic of the disease depend on vaso-motor lesions acting through the communicating branches between the posterior roots of the spinal nerves and the sympathetic. In conclusion, the author stated that the results of his inoculation of animals from the pustules of ordinary small-pox were without result, whereas injections with the blood of purpura variolosa did them harm.

Dr. Kaposi asked why any likeness should be assumed between the pathology of variola and that of zona; the latter was a disease of a single nervous trunk, the former one of the entire organisms; nor could accurate localisation of the pain be expected from patients who became very early stupid, and unconscious in a few hours. The occurrence of ecchymoses in the nervous system in this form of disease was no new fact, and could not explain the lumbar pains which exist in smallpox without hæmorrhage. Would Dr. Neumann pretend to separate 'purpura variolosa' from other forms of variola, when transitional cases often present themselves, and when probably the only reason for the ordinary eruption not occurring in the former is their rapidity? Lastly, he

thought no explanation of the locality of cutaneous eruptions could be accepted which did not take into account the zones of Langer and the hair-regions of Voigt. [See LONDON MEDICAL RECORD, March 4, 1874.]

Dr. Auspitz suggested that lumbar pains are not peculiar to the hæmorrhagic form of smallpox, nor even to smallpox at all, since they occur at the outset of most fevers. He could not admit any pathological resemblance between purpura hæmorrhagica and zona.

Professor Hebra (who was in the chair) remarked that lumbar pains are often most severe in the non-malignant cases of variola. As to the distribution of ecchymoses and all kinds of eruption over the skin, he believed it to follow definite laws of which the three factors are nervous supply, the regions of splitting observed by Langer, and the hair-territories of Voigt. On this subject, he hoped before long to make a communication to the society.

P. H. PYE-SMITH, M.D.

BERGERON ON SPONTANEOUS FRACTURES AND DISLOCATIONS IN ATAXIC PATIENTS.—Under this title M. Bergeron (*Le Progrès Medical*) has just published an interesting article which is based on a fact that M. Richet mentioned in one of his last clinical lectures. The readers of the *Progrès Medical* are already acquainted with the subject, for they have had the first communication made by M. Charcot to the Société Anatomique.

Dr. Charcot's case, which gave rise to discussion in which several members of the Society joined, has been since reproduced in all its details in the *Archives de Physiologie* (Jan. 1874), and has besides been inserted by M. Forestier in his Inaugural Thesis (*Thèses de Paris*, 1874). As in cases already mentioned, in the one related by M. Richet, the fracture occurred spontaneously without any traumatic cause, and the union was rapid. On the patient dying M. Richet found an osteitis, which had thinned the bone, and to which he attributed the occurrence of the lesion. This osteitis, which would itself seem to be dependent on the morbid changes in the spinal cord, and at the same time the cause of these spontaneous fractures, would also constitute a condition eminently favourable to a rapid reunion. It is possible that this explanation may be correct. However we ought to receive it with some reservation, and for these reasons; 1. Because in Dr. Charcot's first patient, one of the fractures—that of the left thigh—did not unite; and 2. Because in old men in which an analogous osteitis occurs, as M. Richet remarks, the formation of a callus takes place very slowly, whenever it does take place.

However unimportant these explanations may be, the fact recorded is nevertheless extremely instructive. It remains to be studied, and for the future to decide.

M. A. Bergeron concludes his article with some remarks on spontaneous dislocations in patients suffering from locomotor ataxy. This is a new subject in surgery, but it dates back six years, when M. Charcot made known, for the first time, the occasional existence of this complication with sclerosis of the posterior columns of the spinal cord. A patient suffering from locomotor ataxy, says M. Bergeron, was admitted under the care of M. Béhier. Without any exertion or effort, a dislocation of the shoulder-joint ensued. The patient died of the ataxy, and at the necropsy there was found, not a pure and simple dislocation, but a disruption of the head of the hu-

merus, which, thus deprived of its ligaments and muscles of attachment, had become displaced, and simulated a dislocation.

J. LOCKHART CLARKE, M.D.

MEDICINE.

ROBERTS ON REST IN THE TREATMENT OF CHEST-AFFECTIONS.—Dr. F. Roberts (*Practitioner*, June, 1874) recommends the following methods of treating various diseases of the chest.

Pleurodynia is to be treated by applying two or three strips of plaster firmly round the side over the seat of pain. The emplastrum roborans is a good form of plaster for these cases. In pneumothorax and pleurisy the strapping needs to be very firm and resisting, and therefore the best form is that of plaster covered over with two or three layers of strips of bandage, steeped in a mixture of gum and chalk. Should the pleural sac be much distended, however, the best plan of treatment would be to remove the air from the pleura by means of the aspirator, and then immediately to put on the apparatus. In acute pneumonia a complete state of general rest must be enforced. The physical examination of these cases should be made as seldom, and with as little disturbance to the patient, as possible. The patient should be instructed to limit the number of his respirations, to check his cough, and to speak as little as possible. Strapping does not appear to benefit these cases.

In acute bronchitis the object should be to disturb the patient and the respiratory organs within due limits, and to try and empty the bronchial tubes. Frequent examination is here to be commended; the patient should be directed to take full and deep inspirations from time to time, and coughing is to be encouraged. A half-sitting posture should be adopted, and prolonged sleep is to be forbidden at night as well as in the day time. The act of coughing is often aided by applying a bandage tolerably firmly round the abdomen, including the lower margin of the thorax.

In cases of broncho-pneumonia, the treatment must be determined by the exact conditions of each case.

H. SUTHERLAND, M.D.

FRÄNZEL ON ACUTE PURULENT INFLAMMATION OF THE MEDIASTINUM IN TYPHOID FEVER.—Dr. Fränzel of Berlin records a fatal case of this very rare complication of typhoid fever in the *Berliner Klinische Wochenschrift* of March 2, 1874. A waiter aged fifty-two was admitted into the Charité 'in the course of the second or third week of the disease.' There were no uncommon symptoms: the cardiac dulness was found normal at the first examination: slight dulness existed at the left posterior pulmonary base. The patient was treated with baths. A few days after admission the stools became more frequent and liquid; on the sixth day the strength was manifestly failing, and liquor ferri sesquichlorati, in doses of five drops every two hours, was prescribed, with red wine. In spite of the continuance of the diarrhoea for the next six days, the condition of the patient was not apparently worse on the thirteenth day of his residence in the hospital; the iron was now stopped. Next day a new set of phenomena began. The patient was found to be worse; the pyrexia was increased; there was com-

plaint of sore throat, and pain and tenderness in the neck, and the pharynx presented the signs of catarrh. Slight dulness was found at both posterior lung-bases. On the following evening great dyspnoea set in, compelling the erect posture, and preventing sleep. The appearance of the patient next morning was that of extreme orthopnoea and collapse. The countenance was anxious and cyanosed; the respiratory movements were frequent and superficial, with loud groanings and powerful action of the extraordinary muscles of inspiration. The patient complained of pain in the neck—back and front, and of a severe feeling of constriction in the chest. The jugular fossa in the neck was discovered on examination to have completely disappeared, and to be replaced by a soft somewhat doughy prominence, which extended upwards as far as the lower border of the larynx, and laterally to the outer head of the sterno-mastoid muscles. No other swelling was appreciable about the neck, but all the muscles were tender to the touch. There was a constant and profuse flow of saliva from the mouth; the palate and pharynx were more hyperæmic and swollen than on the previous day; deglutition was not seriously affected. The larynx was apparently healthy. Marked dulness on percussion existed over the manubrium sterni, decreasing in intensity downwards, but reaching the third rib. There was no marked alteration of the pulmonary signs beyond general feebleness of the respiratory murmur. Fränzel's diagnosis was phlegmonous inflammation of the pharynx with suppuration of the connective tissues between the deeper cervical muscles, and extension of the process into the mediastinum. Death speedily followed from suffocation.

The results of the *post mortem* examination confirmed the accuracy of the diagnosis. The subcutaneous and intermuscular connective tissue of the front of the neck was found highly cedematous. The swelling was continued into the connective tissue of the anterior and posterior mediastina, and the exudation here was more opaque and in places even distinctly purulent. The trachea in its whole length was firmly compressed from before backwards. The mucous membrane of the pharynx and œsophagus was swollen, hyperæmic, and soaked with semi-purulent fluid. The laryngeal mucous membrane was not cedematous, but on the right side of the epiglottis, on the upper border, was found a shallow, rather elongated ulcer. The other viscera presented the appearances usually found in typhoid fever.

Dr. Fränzel remarks that this is the first instance on record in which typhoid fever has been complicated with fatal mediastinitis. The inflammation of the connective tissue in this situation was manifestly an extension of the phlegmonous pharyngitis, but it is not so easy to account for the development of the latter disease. The author himself believes that it must be attributed to the prolonged use of the liquor ferri sesquichlorati. Such a result might *à priori* be expected when the frequency of slight ulceration of the mucous membrane of the throat in typhoid fever is considered: and Fränzel's experience of the drug has verified this opinion. Having had occasion to prescribe liquor ferri sesquichlorati in numerous cases of intestinal hæmorrhage in typhoid fever, he observed among these a disproportionately large number of severe affections of the pharynx. As for the treatment of acute purulent mediastinitis—neither bleeding nor even tracheotomy can be expected to be of any use. Long and deep incisions, carried down

to the trachea, would seem to Fräntzel to be the only rational measures to be adopted.

J. MITCHELL BRUCE, M.D.

SURGERY.

AZÉMA ON TRAUMATIC ANEURISM OF THE DORSALIS PEDIS ARTERY: ANOMALOUS COURSE OF THE ANTERIOR TIBIAL.—At the meeting of the Société de Chirurgie de Paris on May 6, 1874, M. Azéma, of the Île de la Réunion, communicated a rather unusual case. A man seventy-one years of age slipped and twisted his foot. This caused the formation of a small traumatic aneurism, only of the size of a nut, on the dorsalis pedis artery just below the annular ligament. After a few months the tumour had attained the size of a pullet's egg. There was a marked bruit. It was so painful as to prevent the patient from sleeping. Compression of the femoral artery stopped the pulsation and bruit.

It was determined to tie the anterior tibial in the lower third of the leg, but on cutting down in this situation M. Azéma could find no artery, though he met with two veins and the nerve. As the course of the artery was anomalous, he recommenced the operation in the upper third of the leg, and there he exposed an artery, pressure on which stopped the pulsation and bruit of the aneurism, and the ligature of which cured the patient. M. Azéma concludes that the dorsalis pedis artery in this case was furnished by the anterior peroneal. Another speaker related an incident which happened in an anatomical examination at Paris, where the candidate, having to tie the anterior tibial artery, could find only a single vein and no artery at all.

[We must confess to some doubts, both as to the propriety of the surgical treatment in this case, and as to the accuracy of the anatomical details. With regard to the former, surely a small traumatic aneurism, the symptoms of which were immediately controlled by compression of the femoral, and which was subcutaneous, might have been treated by some less dangerous operation than the ligature of the anterior tibial artery at the age of seventy-one. Intermitting digital pressure on the sac and on the artery leading to it, is ordinarily quite sufficient in such cases, without exposing the patient to any pain or risk. Yet, if we understand the account aright, the surgeon resorted at once to the ligature, without even giving a trial to any milder measure.

As to the anatomy, if the dorsalis pedis were furnished by the anterior peroneal, which is a branch of the peroneal from the posterior tibial at the back of the leg, how could its pulsation be stopped by tying the anterior tibial on the front of the leg? Allowing that the artery was really absent in M. Azéma's operation, and in the operation on the dead subject which was referred to in the debate (and there is no strict proof that it was really absent in either case), it would seem more probable that it was merely an accidental deviation of the anterior tibial from its usual course. The dorsalis pedis is known to be often deflected outwards from the line which it ordinarily follows, and a similar deflection might in this case have occurred at a higher point in the leg.—*Rep.*]

LE DENTU AND OTHERS ON THE TREATMENT OF TETANUS BY CHLORAL.—At the Société de Chirurgie de Paris on May 6, a discussion took place

on the treatment of tetanus by chloral. M. Le Dentu referred to five cases under M. Verneuil's care, in which cases of tetanus so treated had recovered; but it does not seem to have been alleged that these were of the acute form, and M. Lefort was of the opinion that chloral, whether given by the mouth or injected into the veins, is useless in acute tetanus.

M. Tillaux, however, related a very striking case as follows. A woman who had had a hydatid cyst of the liver opened, complained, about ten days afterwards, of difficulty in mastication, and next day had decided trismus; chloral was given by the mouth but was vomited. This was the day before the discussion. On that morning she appeared dying; the face was blue, asphyxia threatened, the mouth could not be opened, the conveyance of fluid into the pharynx set up spasms. An injection of four grammes (about 3j) of a solution of one part of chloral in two of water was passed into the cephalic vein. She then opened her eyes and began to speak. Six grammes more were injected, producing universal relaxation and calm slumber. She slept for two hours, and then awoke and was calm; but there were slight rigidity and mild spasms. M. Tillaux promised to let the Society know the event of the case.

M. Verneuil testified to the efficacy of chloral in calming the spasms, and seemed to attribute the recovery of his five patients to its use.

T. HOLMES.

SYPHILOGRAPHY.

FOURNIER ON TERTIARY SYPHILIS.—Fournier (*La France Médicale*, May 23, and June 3, 1874) defines tertiary syphilis to be that group of manifestations which is developed when a long interval has elapsed since contagion. He says the natural tendency of syphilis is to reach the tertiary period, though it is not of necessity attained by all the affected. He believes the following reasons to explain why some individuals are attacked more than others. 1st. The conditions peculiar to the individual, such as weakness of constitution, scrofula, lymphatic or anæmic conditions, chronic alcoholism, old age, and any depressing cause, though they have a certain predisposing power, may not unfrequently be all absent and yet the disease may be developed. 2nd. A far more potent cause of tertiary affections is absence or insufficiency of treatment in the early period of the disease. Throughout his paper Fournier insists upon the disastrous effects produced by 'expectant' or 'simple' treatment of syphilis. In attempting to distinguish between the periods of secondary and tertiary affections respectively, Fournier acknowledges the impossibility of laying down a hard and fast line between the two periods. The disease passes from the earlier to the later stages in one of two ways. In one, the phenomena gradually change from one form to the other, or the later ones appear before the earlier forms have wholly disappeared. In the other, a more habitual one, there is an interval of quiescence before the tertiary affections break out. As a general rule, tertiaries are rare before the second or third year, while the interval may be prolonged frequently for ten to twenty years; and Fournier relates a case from his own experience where the tertiary period had continued fifty-five years after infection. The general character of the tertiary period is one of full health interrupted by morbid phenomena, which have

no stated period for their appearance but may occur and recur during many years, indeed, while life lasts. When present they are scattered, even isolated or solitary, while no part of the body is exempt; their outset is insidious, their development slow, and in many latent. Their anatomical seat is the parenchyma of the tissue attacked, the deeper structures rather than the superficial part. Thus they destroy the tissue or organ in which they are developed. They set up two kinds of tissue-change: one, inflammatory fibrous increase and contraction of the parenchyma; the other, the gummy tissue peculiar to syphilis. Lastly, tertiary syphilides are almost always curable.

In establishing the diagnosis of tertiary syphilis, attention must be paid to three points: 1. Special characters; 2. Coexistence of specific affections elsewhere; 3. Previous syphilitic affections. But any of these conditions may be wanting, and render the diagnosis often dependent on two or even one of the others. With regard to the special character of the affection, unfortunately tertiary syphilitic affections more often want special characters than possess them. Most frequently, again, the affection is isolated, the sole one present. Again, the history of previous syphilis is most commonly wanting, in women as often as in one out of four or five cases. Former syphilis is often forgotten or not suspected, on account of the length of time that has elapsed, and the determination of some patients to deny any fact which casts a slur on their moral conduct. This obstinacy, combined with the social reputation of the patient, sometimes puts the questioner off his guard. All these circumstances impede the practitioner in reaching a true diagnosis.

The prognosis of tertiary syphilis is always serious, often grave, and more often fatal than is generally believed. It is influenced by position and by the condition of the patient. Nevertheless, speaking generally, tertiary affections are eminently curable [*i.e.* the lesions, not the diathesis]. Though the iodides alone, or combined with mercury, are the remedy *par excellence*, there are cases in which both these remedies fail. For example, over the inflammatory changes produced in an organ by the irritating presence of the syphilitic affection, mercury and iodine have little or no influence. In conclusion, Fournier insisted most strongly on the great importance and possibility of *preventing* tertiaries by a well-sustained and prolonged treatment of syphilis in its early stages. He attributes much of the subsequent disease to the inefficient treatment of the patient during the first two years after infection, and utters a powerful protest against the custom of withholding mercury when the early symptoms begin to abate. At this time, it should be continued steadily for several months after the patient is apparently well.

BERKELEY HILL.

PUBLIC HEALTH.

PROPOSED SANITARY LEGISLATION.

The first attempt to realise the aspirations of the Public Health party and the hopes which had been raised by the advent of the present *sanitas sanitatum* Government to power, is not very encouraging, and hardly justifies the exulting cheers with which Mr. Stansfeld's downfall was received by certain sanitary reformers.

Mr. Sclater Booth and Mr. Clare Read have introduced 'A Bill to amend and extend the Sanitary Laws.'

The first part of this measure contains 18 clauses, relating to the Public Health Act, 1872—a series of amendments, verbal and explanatory, of the provisions of that Act. It is difficult to fix on one which can be fairly called an important extension of sanitary law, or a recognition of any hitherto neglected principle of legislation. They simply supply notorious deficiencies in that Act.

Clause 5 directs that the joint action of several local authorities in the appointment of a superintending medical officer of health shall be in a manner prescribed by the Local Government Board:—thus pledging that Board to act regularly and systematically in this matter.

Another application of the principle of combination is shown in Clause 12, by which the Local Government Board is empowered to order all the riparian authorities connected with a port, to send representatives to the port authority; though it is difficult to comprehend why 'two or more' riparian authorities should be ordered to unite in electing only one representative. Several port authorities on the same coast or river may also be combined, with a new title, as a united district.

These clauses are the first distinct admission of the principle of unification, followed by combination, of local authorities.

Clause 16 gives the Local Government Board power, by provisional order, to alter, extend, or diminish the areas of local sanitary administration.

The second part relates to other Sanitary Acts.

Clauses 19, 20, and 21, are simply to fortify the provisions of existing enactments:—enabling the police officer who may act in default of the sanitary authority, under Section 16 of the 'Sanitary Act, 1866,' to recover his expenses from that authority;—enabling the Local Government Board to enforce, *by mandamus*, any order made under the celebrated 49th section of that Act; and enforcing by penalty the removal of nuisances, and the cleansing of receptacles, &c.

Under the third head—Constitution and Election of Local Board—there is little of importance. Clause 25 empowers the Local Government Board to settle, after local inquiry, disputes as to boundaries, of which, according to the evidence given before the Boundary Committee, there is an abundant crop ready for adjudication. Clause 28 also empowers that Board, on application and after inquiry, to increase or diminish the number of members of local boards.

Under the fourth head—Provisions as to the Acquisition of Property—Clause 33 makes an important addition to, and confirmation of the powers of local authorities, enabling them to purchase water-mills, dams, &c., which are often serious impediments to the improvement of the public health.

Under the fifth head, 'Borrowing Powers,' conferred by the Act of 1858, may be extended in most cases from 30 years as now, to 60 years in future. This also is an important amendment of the law; but the term of borrowing might well be further extended, for the more permanent works.

Nothing need be said about the sixth head—Audit of Accounts.

The seventh head—Bye-Laws—contains some useful additions to local powers. Clause 41 prohibits the commencement of any works of which notice,

plan, or description may have been laid before the local authority, until approved by such authority. The power of making bye-laws in regard to the walls of buildings, is extended by Clause 44 to roofs, foundations, and water spouts. By Clause 45, the lodging, and other treatment of hop-pickers, may be regulated by bye-laws; and the confirmation of regulations under the Common Lodging-Houses Act, 1851 (omitted from the Acts of 1871 and 1872) is transferred from the Secretary of State to the Local Government Board;—the powers of the Central authority, with regard to Common Lodging-Houses being also extended (Clause 47) by removing the restriction contained in Section 35 of the Sanitary Act, 1866.

Under the eighth head—'Miscellaneous,'—the most important provision is that of Clause 50, for the closing of wells and pumps which supply polluted water. Clause 51 enables the Local Government Board to declare that any hospital for the reception of infectious cases which is within a convenient distance of the district of the local authority, shall be deemed to be *within* that district. Sections 51 and 52 of the Public Health Act, 1872, which authorise the destruction of 'infectious bedding,' and which regulate the treatment of persons suffering from infectious disease on board ship, are by Clause 52, to be extended to the metropolis. By Clause 54, the provisions of the Nuisances Removal Act for England (Amendment) Act, 1863, are to extend to milk. Clause 55 empowers any justices of the peace to grant to every sanitary officer a warrant of entry and search for unsound food of all kinds. By Clause 56, there is to be a penalty of 20*l.* upon lodging-house keepers for false representation with respect to infectious disease.

These various corrections and supplements to our sanitary code are of a practical kind, and should doubtless be enacted. But they only touch the outside of much greater questions. Such imperfect legislation makes one call the more loudly for a general revision and consolidation of our many complicated sanitary laws, to which this Bill, if enacted, will make another addition, for the benefit of the lawyers.

The great *desideratum* remains unnoticed and unprovided for,—namely, the want of properly constituted authorities, of uniform jurisdiction, and of like nature and composition, in every district, whether urban or rural. Preparatory to this unification of authority, there must be a rectification of areas for statistical and administrative purposes. We are surprised that none of the recommendations, made by the Select Committee, 1873, on Boundaries of Parishes, Unions, and Counties, are to be adopted. Certainly, on this question, Mr. Stansfeld held sounder and more enlightened views than his successors in office appear to hold.

H. W. RUMSEY, M.D. (Cheltenham.)

OPHTHALMOLOGY AND OTOLOGY.

ROBERTSON ON REPOSITIO CILIORUM FOR TRICIASIS.—This operation—recommended by Celsus—has again been brought to the attention of the profession by Dr. Argyll Robertson in the *Edinburgh Medical Journal* of May. Few text-books make any mention of this simple method; and its reintroduction,

about twelve years since, is due to Dr. Snellen, of Utrecht. The following is the method of operating. A very fine curved needle has the two extremities of a very fine waxed silk ligature (or hair, as Celsus directs) passed through its eye. The needle, being firmly grasped by suitable forceps, is then passed through a narrow fold of skin, at the very margin of the lid, close to one of the inverted eyelashes. The point of introduction should be external to the point of emergence of the eyelash, but as close to it as possible; and the needle should be brought out after passing through about three-fourths of a line, or a line under the skin. The needle and ligature should be drawn through until a small loop alone remains, when, by means of a fine pair of forceps, the eyelash is passed through the loop. Traction is then made on the ligature, and the loop with the entangled eyelash is drawn through the tunnel in the skin.

KEYSER ON 132 CATARACT EXTRACTIONS.—The *Philadelphia Medical Times* for May 23 gives an abstract of a report read by Dr. Keyser at the meeting of the Pennsylvania State Medical Society, on 132 cataract extractions made by him during the last six years, on patients ranging from seventeen to eighty-two years of age. The success of these he classifies with regard to vision as follows:—86 $\frac{4}{11}$ per cent. as perfect, 6 $\frac{9}{11}$ per cent. as moderate, 3 $\frac{3}{8}$ per cent. as imperfect, and 3 $\frac{3}{8}$ per cent. as complete loss. It must, however, be noted that he considers vision to $\frac{1}{10}$ as perfect, from $\frac{1}{10}$ to $\frac{2}{20}$ as moderate, and in no case did the patient recover $\frac{20}{xx}$. Twelve of the cases were equally divided between Daviel's corneal, Pagenstecher's, Liebreich's, and Bowman's suction methods, the remaining one hundred and twenty being operated on by Von Graefe's modified linear method, the incisions being made 'in the sclerotic, beginning at the sclero-corneal junction, and the most of them brought out in the same with a large conjunctival flap, while in others the incision was brought out in the cornea close to its edge. Those brought out in the cornea did not heal so quickly, although quite as well, when there was a conjunctival flap.' Astigmatism, requiring the use of cylindrical glasses, was found in fifty-eight cases after operation.

FITZGERALD ON THE OPHTHALMOSCOPIC APPEARANCES OF THE OPTIC NERVE IN CASES OF CEREBRAL TUMOUR.—In a paper on this subject in the *Dublin Journal of Medical Science*, June, Dr. Fitzgerald relates a case of *Stauungs-papilla*, and gives a short *résumé* of the theories which have been put forward to account for this congested condition of the disc in cases of cerebral tumour. He particularly desires to correct what he considers a widely-spread but erroneous impression, 'that Von Graefe regarded the *Stauungs-papilla* as *absolutely* diagnostic of the presence of a cerebral tumour,' and points out that Graefe looked upon this condition of the disc as 'merely the expression of increased intracranial pressure.' Dr. Fitzgerald concludes his paper by insisting that, though the appearances of the disc in *Stauungs-papilla* cannot be looked upon of themselves as of any special diagnostic value, those appearances, combined with a careful study of all the symptoms in any particular case, must prove of invaluable assistance in forming a diagnosis.

BERGERON ON SPONTANEOUS IRITIS SUPERVENING IN THE COURSE OF A BLENNORRHOEA.—

In *La France Médicale*, M. Albert Bergeron relates a case which has occurred in the Hôpital de la Charité under the care of M. Gosselin, where the iris alone was affected during an attack of blennorrhagia, neither traumatic injury, rheumatism, nor syphilis being detected. He considers it an example of the monarticular rheumatic type, differing from the ordinary rheumatismal form of iritis by the latter almost invariably affecting the two eyes.

BURNETT ON MENIÈRE'S DISEASE.—In the *Nashville Journal of Medicine and Surgery* for May, Dr. Burnett relates a case of Menière's disease, or, as Knapp and other American surgeons prefer to call it, apoplectiform deafness. In this case, which Dr. Burnett considers a typical one, a single application of 'electricity' restored for several hours the hearing power of a previously 'completely' deaf ear. Unhappily, though without any assigned reason, only one application was made. He concludes that there is such a disease as Menière's disease, which is caused by a sudden extravasation of blood or serum in the auditory nervous apparatus, and in those where the range of audition is affected located in the cochlea, and considers that the vertigo of the affection is probably entirely of a reflex character, as there is 'not sufficient evidence to show that the office of the semicircular canals is to regulate the equilibrium.'

W. LAIDLAW PURVES, M.D.

DERMATOLOGY.

HILLAIRET ON LEPROSY.—M. Hillairet relates the following case from his wards in St. Louis Hospital (*L'Union Médicale*, 1874, p. 154). The patient, a Mexican, found that the great toe of the right foot had lost sensation as early as 1861, when he was twenty years old. For the next four years he was engaged in civil war, and suffered no further inconvenience; but in 1865 anaesthesia rapidly spread up to the right knee. A patch appeared on each cheek in 1868, and the patient then came to Paris and put himself under treatment. In December 1869, after five months' treatment with alkaline baths and applications of glycerine to the 'tubercles' of the cheeks, they had almost disappeared, though the leg was still insensible. He then began taking arsenic, but was immediately afterwards attacked by an outbreak of leprous nodules, which appeared on his face and body, and rapidly ulcerated. This continued from January to August 1870, and became steadily worse during the following winter, when Paris was besieged. 'At the time of the Commune there was a period of arrest, and even a slight improvement.' In June 1872 the patient entered the hospital, St. Louis, under M. Hillairet, who gave him tonic regimen and gradually destroyed the nodules with carbolic acid. On January 1, 1873, the face had again become covered with flattened nodules, which deformed the features and even invaded the tongue. Similar lesions occupied the hands and feet, but his general health continued good. In February, however, he began to vomit after each meal, and the urine was then (apparently for the first time) examined, and found to be albuminous, with a low specific gravity. Epistaxis succeeded, the temperature became low, and death ensued three weeks after the first symptoms of constitutional disturbance.

At the necropsy, an ulcerated patch was found on each side of the larynx above the vocal cords. There were extensive pleuritic adhesions, with miliary tubercles, on the right side; and the corresponding lung contained two vomicae at the apex and small masses of unsoftened tubercles. The kidneys were atrophied and granular, presenting all the characters of chronic interstitial nephritis. The liver was affected with lardaceous degeneration, as were the renal arteries, and probably the spleen. The brain, cord, and nerves were unfortunately not examined. No dropsy was observed during life, and there was an entire absence of general symptoms until the last attack, the symptoms of which, including the low temperature, may all be referred to uræmia. There were, however, no convulsions. The following are the temperatures of the last few days of life:—

| Morning. | Evening. |
|----------|----------|
| 97°34 | 95°18 |
| 97°88 | 97°52 |
| 96°08 | 95°9 |
| 96°08 | 96°8 |
| 95°18 | 95°18 |
| 95°36 | 95°54 |
| 95°54 | 95°36 |
| 95°36 | 95°36 |

MICHELSON ON TRANSFERENCE OF RINGWORM FROM A CAT.—Dr. Michelson (*Berliner Klinische Wochenschrift*, 1874, no. 11) relates the following interesting case. Three children and their father and mother were found to be affected with ringworm. It appeared first on the scalp and body of the children, and was evidently thence transferred to their parents. In seeking for the primary cause of contagion, Dr. Michelson discovered that a cat with which one of the boys had been playing was the subject of scabies; and, when the crusts were examined, beside acari and their eggs, a multitude of spores and filaments appeared, which were recognised by the writer (supported by the judgment of Professor Kœbner), as *Trichophyton tonsurans*. Pieces of the crusts from the cat were next bound on to the arms of three medical students. Itching soon followed, and became so violent that one of them took off the bandage, and cured its effects with balsam of Peru. The other two experimenters were rewarded by a patch of apparently ordinary scabies, which died away of itself in ten or twelve days from the date of inoculation. One of them showed no further effects of the experiment; but the other, some weeks later, found on the place where the crust had been applied a patch of *Tinea circinata*, which furnished specimens of the *Trichophyton tonsurans*.

The entire history (which is minutely related, and illustrated with figures of the acarus and the fungus) shows the correctness of Gerlach's conclusion, that the scabies of cats cannot be transferred to man. This does not appear, from the figure and description, to depend on a specific difference in the acarus of human and that of feline itch, but on the change of habitat. It also shows that animal parasites are very efficient carriers of epiphyta. This was well shown by the fact that scales from the patches of ringworm in the boy, which were transferred to the arm of the same person, produced no result, while the crusts from the cat succeeded. [At a recent meeting of the Société Méd. des Hôpitaux, MM. Hillairet and Besnier related cases of the transmission of *Herpes circinatus* and *Herpes tonsurans* to human beings from horses and from a calf.—*La France Méd.*, May, 1874, p. 301.]

HILLER ON ONYCHOMYCOSIS.—Dr. Hiller records the following case (*Berliner Klinische Wochenschrift*, May 18, 1874). A soldier, twenty-two years old, came to him with one thumb greatly inflamed, and the nail loosened. A large bleb was opened, and thin yellowish fluid ran out, with numerous white flakes. On microscopic examination, beside leucocytes and cells of the rete mucosum, there was found abundant branching mycelium, with undivided hyphæ, sporangia, and numerous small, bright, nucleus-like spores. The fungus was referred to *Mucor mucedo*, and had evidently been derived from the dungheaps of the regimental stables. A second superficial abscess was opened, from which only pus and spores escaped; the nail, which had become very loose, was removed, a fresh one formed, and the whole thumb soon returned to its normal condition. The man's hands had been excessively dirty, and a deep black deposit was found between his nails and the flesh, separating them more than natural, and thus forming the most favourable bed for the growth of spores. They had penetrated under the nail by this channel, and there excited the superficial but extensive inflammation. [The mould does not appear to have invaded the nail itself, as in other cases of onychomycosis proper.—*Rep.*]

NEUMANN ON ERUPTION FROM POTASSIUM BROMIDE.—Dr. Neumann (*Anzeiger der K. K. Gesellschaft der Aerzte in Wien*), publishes a case of a pustular and bulbous eruption on the scalp, cheeks forehead, and legs of a child five months old, who had been taking this drug for convulsions. The affection appeared after four drachms had been taken. Microscopical examination (apparently from the same case) showed that the hair-follicles and sebaceous glands were chiefly implicated.

P. H. PYE-SMITH, M.D.

COURRÈGES ON ALOPECIA.—In an article on alopecia published in the *Thèses de Paris*, 1874, no. 76, Dr. Courrèges states that he has demonstrated that the fungus of the *Alopecia areata*—the *Microsporon Audouinii*—is not situated, according to the statements of Gruby and Bazin, in the hair, nor even around it, but in the most superficial portions of the horny layer of the epidermis. M. Malassez has made this cryptogam a subject of special study, and presented a note regarding it to the Société de Biologie on December 27, 1873. The fall of the hair would not be due to a cryptogamic change in it, but to a vice in nutrition, induced by the presence of the vegetable parasite in the superficial parts of the epidermis. M. Courrèges therefore admits, like Gruby, Bazin, and Luiller, that alopecia is of a parasitic nature, but in an indirect manner. He rejects Hebra's theory, which makes alopecia depend on a disturbance of the organs of nutrition.

Alopecia achromatosa and *alopecia decalvans* would therefore be only two forms of the same disease. With regard to treatment, M. Courrèges prefers shaving to epilation, which is in conformity with M. Malassez's latest researches. The head should be shaved at least once a week, or even twice, and then washed with a solution of hydrochlorate of ammonia and corrosive sublimate, each one gramme, in 500 grammes of water. Sometimes M. Courrèges substitutes an ointment of 1 gramme of sulphate of mercury to 30 grammes of lard.

BROWNE ON A METHOD OF TREATING TINEA TONSURANS.—Dr. Edgar A. Browne, writing to *The*

Practitioner of May, recommends the following method of treatment as requiring no attention on the part of a nurse or parent, and needing only to be renewed at intervals of three or four days. A margin of healthy hair is to be cut quite short or shaved round the patch. A brisk rubbing with the oleum picis rectificati, or some similar hydrocarbon, is the next stage, and the reddened and saturated patch is to be thickly dusted with a powder composed of tannin, iodine, and gum arabic. This is to be moistened with a few drops of the oil, and gently but firmly pressed into the skin with the end of a small cork. The process is repeated till the whole patch is covered with a layer of paste about an inch thick, which is allowed to dry. The firm hard scab thus formed may be left undisturbed for three or four days, when it should be moistened and scraped off, and a fresh application made.

DUHRING ON PSORIASIS AND SYPHILIS SQUAMOSA.—Dr. Duhring, in a clinical lecture printed in the *Philadelphia Medical Times* (February 7, 1874), arranges the diagnostic signs between these two diseases as follows. *Age.*—Psoriasis is not uncommon in children; the scaly eruption of syphilis is almost entirely confined to adults. *Transmission.*—Psoriasis is often hereditary, but congenital syphiloderma is rarely or never of the scaly variety. *History.*—There will be generally an account of a precisely similar attack of psoriasis before, and there may be a history of a primary syphilitic lesion. *Duration.*—A tendency to relapse is characteristic of psoriasis, but a syphilide, when once thoroughly cured, rarely returns. *Symptoms.*—The general health in psoriasis is good, whereas some amount of cachexia is present in all cases of scaly syphilitic eruptions. The form of the eruption is more regular in psoriasis than in syphilis; and its edges are well-marked and sometimes raised in the latter, but fade gradually into the surrounding skin in psoriasis. Psoriasis is far more symmetrical than the syphilide; and, though no region is exempt from either, the former, as a rule, is more extensive, and seldom fails to attack the elbows and knees, while the latter may be found affecting the palms and soles alone. Itching is characteristic of psoriasis, absent or slight in syphilis. Thickening of the cutis is characteristic of a squamous syphilide, as is also the presence of papules, pustules, or any other lesions than scales. The bright colour of psoriasis, and its abundant, silvery, loose, and imbricated scales, contrast strongly with the 'lurid' hue and scanty, dirty-white, adherent scales of syphilis. A patch of psoriasis bleeds easily when the scales are removed, but one of syphilis is far less vulnerable. Moreover, the former disease is never complicated with ulceration; and the subsequent maculæ are less deep in colour, and less persistent than those of syphilis. Lastly, local treatment affects psoriasis, and has no influence on syphilis: the former is benefited by steel or arsenic, the latter by mercury or iodide of potassium.

P. H. PYE-SMITH, M.D.

PSYCHOLOGY.

SAMT ON THE PHYSICAL METHOD IN THE STUDY OF MIND.—At the Medico-Psychological Association of Berlin, held in November, 1873, and

reported in the *Berliner Wochenschrift* of 9th a discourse was given by Samt on 'The Physical Method in Psychiatry.' The psychologist, said he, studies manifestations of the mind and the brain, understanding by the former perception, ideation, and will; by the latter, the various parts of the nervous system. The proofs of this arrangement stand in two categories; the first, which comprises the proofs derived from the history of development and comparative anatomy, can only affirm a relation. Not much can be said of the history of development, for we know nothing in detail about periods of development of the mind corresponding to certain stages of development of the brain. Comparative anatomy is more satisfactory, but it has no causative significance; for, even though empirical observation declares that as we proceed higher in the animal kingdom, from the coelenterata to man, the development of the brain and the mind show an absolutely proportioned relation, still the mind might always be regarded as extracerebral, the brain being only the means of soul manifestation. In the second category come the proofs by pathology and experiment, which are stringent, and maintain a relation of causality. The demonstration depends on a general principle which may be called that of 'empirical actualism,' (*empirische Actualismus*). When the relation of brain and mind is proved as a fact, the manifestations of the latter being without exception functions of the former, the question arises, in what manner this relation occurs. Here we are in presence of the two limits fixed by Du Bois-Reymond, the second of which Samt would extend by dividing the manifestations of mind into the conscious and the unconscious, the latter of which, however, can only be motor, for unconscious perception or unconscious ideation is a nonentity. As to the unconscious phenomena of mind, he mentions that they are to be understood mechanically, but only on the presupposition that they really happen without consciousness, and he explains this point by two examples and an experiment which he borrows from Goltz, who found that a frog deprived of the cerebral convolutions contrives to avoid exactly obstacles placed in his way, and that the direction of his efforts varies according to the position of the impediment. The second example is a very complicated one, and represents a general who, in a feigned state of somnambulism, designs an ingenious plan of battle. To these examples are added the experience derived from subjective observation. The reasoning is apparently as follows. Whoever, from the actions of a certain person rendered unconscious through the action of medicines, or from those of a frog deprived of its brain (however voluntary they seem, though the individual knows nothing of them, and the frog can say nothing), maintains that they must be accompanied by consciousness, simply makes an assertion for which he can adduce no proof. But on this acceptance alone the actions cannot be understood, for he must of necessity point out the exact central mechanism, for the adaptability (conformity to ends) of an executed movement depends on consciousness alone and on a suitable apparatus; the second acceptance only of an exact mechanism of the nervous apparatus can be received, since of two views on any matter that one is the best which requires the least amount of theory. Those who maintain that every action which appears voluntary must be followed by consciousness, require, besides Samt's own acceptance (theory) another, viz., that

of consciousness. With the last two theories the debated actions are, however, scientifically incomprehensible; according to Samt's theory, they are to be understood on mechanical principles.

So far, the reasoning is purely theoretical. The lecturer now adduces a practical result which opponents cannot do. It is a known fact, that thoroughly unconscious hysterical persons move about in a co-ordinate manner, as in ascending staircases and performing other complicated movements. This shows that certain actions which seem conscious are, in part at least, without doubt unconscious, for the consciousness of these non-perceptive hysterics has no knowledge of objective signs; the apparatus itself must therefore be responsible for the management, and so the lecturer proposes a scheme for making his views plainer. The conscious phenomena of mind are not to be comprehended on mechanical principles; they constitute the record of Du Bois-Reymond's limitations. But the conscious phenomena of mind are also functions of matter. As the brain-mechanism produces ideas, perceptions, and acts, so does the man think, feel and act, and pathology proves this by the constrained (forced?) ideas, feelings and acts of the insane. He then proceeds to enumerate a third scheme regarding hallucinations of special sense, and adduces hallucinations of hearing as examples, especially in the voices heard by the insane, which afford a direct view of the course of the mechanism, the consciousness hearing the work of the machinery of the unconscious. Finally, the lecturer avoids identifying his psychic unconsciousness with that of Hartmann; his psychic unconsciousness is a brain-function, that of Hartmann is a metaphysical principle without nervous substratum.

In finishing his paper on the nature of mental diseases, Samt went on to say that he was a supporter of the view of the essential differences between diseases of the mind. There are different diseases of the mind just as there are of the lungs or other organs; and the opposite view, which makes them to be different stages of one particular brain-disorder, beginning with melancholia and ending with incoherence or dementia, is proved by observation to be false. Mania, which is the most typical form of mental disease, is quite *sui generis*, is not developed out of melancholia, and does not pass into craziness. *Folie circulaire* proves nothing as to the secondary nature of mania, it is equally a special clinical form with more or less variations; and just as little does a combination of mania and melancholia, which has been noticed in cases of periodic insanity, prove the secondary nature of melancholia. Epileptic and transitory mania must be separated from mania proper, for with it they have nothing in common, and are clinically different. Under the falsely so-called 'transitory mania' we have a moderately well characterised form of acute insanity, of favourable prognosis, complete recovery, and average duration of eight to fourteen days. He then went on to describe a form of incoherence of a *depressed* kind attended with hallucinations, which in pure cases shows a very typical range of development. It is oftenest seen in women at the climacteric. After an incubation period of more or less duration there arises hallucinations of hearing, then of feeling, smell, and taste, with delirium of persecution. Memory and objective judgment may remain intact for years, and there is no transition into an exalted form of the disease. It is generally classed under the generic term 'delusions of persecution,' but these may depend

on the most different states of brain. To it is opposed a form of an exalted kind which has also a typical beginning, and where hallucinations of sight predominate. It is a primary disease and is also of an exalted nature from the commencement, but its course is not yet quite defined. Other forms of insanity are very different from mania and incoherence, and so are the conditions present in fevers. Together with diseases of the mind those psychopathic natures are to be studied which, presenting more or less definite stages of constitution, are arranged in a long series, rising from the speechless idiot at the bottom and passing through a middle stage comprising the morally perverse man or the criminal, culminating at the summit with the intellectually-gifted individual. As regards the connection between changes in the brain-substance and mental perversions, nothing is known. We have isolated anatomical facts which enrich our positive knowledge, but explain nothing. If even we knew the definite changes for paralysis, or the exact microchemical reactions of the ganglion bodies in mania, they would not explain the paralytic and maniacal symptoms of the zone. He therefore thinks it premature to attempt to explain melancholia or mania by anæmia or hyperæmia, or by a plus or minus state of excitement of a hypothetic controlling centre.

T. CLAYE SHAW, M.D.

GRAY ON THE PATHOLOGY OF INSANITY.—Dr. John P. Gray, Superintendent of the New York State Lunatic Asylum, has for several years past been engaged in pathological investigations, and more recently in special microscopic work, and in the number of the *American Journal of Insanity* for January last gives a brief summary of some points of interest.

He states that, although the cases thus far examined may be regarded as insufficient to establish general conclusions, they go to strengthen the conviction sustained by the laws of general pathology, that insanity is a physical disease of the brain, and that the mental phenomena are symptoms; further, that the microscope, with patient and close investigation, will continue to disclose structural changes in the cerebral tissue, as marked as those heretofore unsuspected, when examinations were limited to the scalpel and naked eye; and in these investigations, when the entire range of the disease, in every stage of its progress, shall have been brought under the microscope, we may be able to solve the problem of the morbid processes denominated insanity.

Another conclusion to which these investigations would naturally lead, is, that the variety and changes in the predominant symptoms of insanity may acknowledge their cause, not so much in the variety of lesions as in the special parts of the cerebral centres which are morbidly involved in each case; or, to bring the idea within narrower limits, that emotional, ideational, and motor disturbances, have their foundation in the extent and degree to which the nerve-elements that minister to the execution of intellectual and motor acts are involved in the lesion. When the disease reaches its ultimate stage, all distinctions cease, dementia being the same closing stage of every so-called form of insanity.

NICOLSON ON AUDITORY HALLUCINATIONS.—Dr. David Nicolson, in a paper on the 'Morbid Psychology of Criminals,' (*Journal of Mental Science*, April, 1874) makes some observations on the pathology and seat of auditory hallucinations, with reference to the question whether the seat of the

disorder is in the supreme centres of the brain or in the sensory ganglia. 'If we are speaking,' he says, 'of uncorrected hallucination—hallucination as an evidence of insanity—it is impossible for us to get rid of the testimony which the supreme brain-centres themselves, as the seat of the intellectual faculties, afford as to their participation at least in the morbid process going on. But it is altogether another matter when we come to consider the probable seat of origin of the morbid action; when we come to ask ourselves whether the hallucination arose in some deranged or diseased condition of lower centres, and revealed itself through the higher; or whether any cerebral derangement, giving rise to hallucination, is confined to the higher centres.' Dr. Nicolson sees no reason why the location of the *origo mali* may not be in the higher or lower centres. Prison hallucinations are, in his opinion, examples of the former class. They arise from solitary confinement, with limitation of thought and concentration of ideas in particular directions. The treatment consists in removal to a ward where others are present, and the readiness with which the hallucination is thus cured shows that it was due to some disturbance in those higher centres of the brain immediately concerned in the intellectual processes rather than to any morbid condition in the more remote centres. But while we must accept the possibility of uncorrected hallucination having its primary morbid seat in the intellectual centres of the brain, we are not, he thinks, in a position to deny the possibility of the sensory ganglia being the primary seat of derangement. The ganglia of sensation, in common with every other part of the body, are liable to become the seat of disease, and equally liable to disturbance or derangement of function. They may be the seat of morbid sensorial impressions; these are transmitted upwards to the centres of perception and ideation, where, if they are corrected, the best possible proof, viz., that of the *sane* individual himself, is afforded that he is the subject of a deceptive sensation, which, however, he is able to dispel by the evidence of his other senses and his reason. If the morbid impression is left uncorrected and irrational behaviour comes to be indulged in, the hallucination is an evidence of insanity, but its seat of origin remains the same, *i.e.*, in the sensorium. Again, in an insane person who becomes the subject of hallucination, the pre-existence of insanity from disease of the supreme cerebral centres does not prove that those centres are likewise the primary morbid seat of the hallucination. For, if the disease have existed prior to the advent of hallucination, it is possible to conceive that the particular hallucination did not come on until the general disease had extended to and involved the ganglionic centre to which reference is made. In such a case, the particular hallucination is to be looked upon as having had its seat of origin in the morbid state of the sensory ganglia, notwithstanding the evidence of pre-existing disease of the higher centres. In other words, the seat of origin, as regards the insanity, is not necessarily the seat of origin as regards the hallucination.

The following propositions embrace the leading suggestions.

1. The hallucination may have the same morbid seat as the insanity, and may arise before, with, or after the insanity, *i.e.* its primary and sole seat may be in the higher or intellectual centres of the brain; it may be purely ideational.

2. The hallucination may differ from the insanity (of intellectual centres) in its seat of origin; it may take its rise in the sensory ganglia

a. *Prior to the insanity*: corrected hallucinations becoming persistent, and leading up to insanity;

b. *Subsequently to the insanity*: the ganglia becoming involved, secondarily, in the morbid process; thereafter giving forth morbid impressions which are left uncorrected;

c. *Simultaneously with the insanity*: improbable but not impossible.

The utility of investigation into the primary morbid seat of hallucination bears upon the treatment, in addition to the pathological interest of the question.

WILLIAMS ON PHOSPHORUS IN MELANCHOLIA.—Dr. S. W. D. Williams, the Superintendent of the Sussex Asylum, gives a *résumé* of half-a-dozen cases of melancholia treated by phosphorus (*Journal of Mental Science*, April, 1874.) The medicine used was in the form of the pills prepared by Messrs. Kirby and Co., which are stated to contain each the thirtieth part of a grain of pure phosphorus. The first case was a male, aged fifty-one, agricultural labourer, no hereditary taint, but father given to drinking; admitted September 6, 1873. The attack was pure melancholia, uncomplicated with delusions, and had been coming on for twelve months. Sleeplessness was at first treated by chloral, which was changed for opium and chloric ether. He then began to refuse his food, and on November 12 was ordered one phosphorus pill night and morning. In a few days the depression was less, and in a month had quite left him. The second case was that of a female aged thirty, who recovered from two attacks of melancholia, relapsing almost immediately. She was then put on phosphorus: the third attack only lasted twenty-seven days, and she has now (two months) remained cheerful and well. The third case was also a female, aged fifty-four. The disorder was hereditary, and had lasted five months. She had a constant desire to commit suicide, but no delusion. Phosphorus was given, and persevered with for seven weeks, without any benefit. Opium was then given, with immediate result, and recovery took place. In the fourth case, a female aged thirty-three with a strong suicidal and homicidal impulse, phosphorus was prescribed after she had taken iron and cod-liver oil. She improved so as to be able to employ herself in the laundry, but relapsed, and refused to take the pills. Since then she had become worse. The fifth case was a female aged twenty-seven, who was admitted in an attack which was said to have lasted ten days. Chloral and opium were tried without effect. After taking phosphorus a week she had much improved, and there was every prospect of recovery. The last case was a male patient, aged thirty-nine, who had been intemperate both in smoking and drinking. He suffered from acute mania, which had supervened upon symptoms of locomotor ataxy. The latter increased, but the mania passed off, and was followed by melancholia. Phosphorus was given, and the mental symptoms disappeared, but there was no improvement in the locomotor ataxy.

Dr. Williams remarks that in all these patients there was noticed within a few days of beginning the phosphorus a peculiar coated state of the tongue, not unlike the silvery tongue which follows the prolonged use of arsenic, as stated by Dr. Eames. No toxic or other disagreeable symptoms were observed.

WILKES ON INSANITY DEPENDENT ON SYPHILIS.—Dr. Wilks, after narrating the particulars of two cases of insanity dependent on syphilis (*Journal of Mental Science*, April, 1874), makes some observations upon this question. He is of opinion that the mental symptoms denote no more than the presence of a local source of irritation, and do not in their character point to any new or special cause requiring another form of insanity styled 'syphilitic,' to be added to our nomenclature. The well known local morbid conditions in the brain known as 'gummata,' are efficient causes, and therefore no new ones need be sought. There are also sufficient general reasons for doubting the existence of some other more diffused pathological state of the cerebrum proper, which can be attributed to syphilis. The word disease is so commonly used in two different senses, that it is important we should more distinctly define its meaning. At one time a wide and theoretical signification is given to it, and at another time it bears only a precise pathological interpretation. If we take affections of the cerebro-spinal system we find that they fall into two great classes, according as they are organic or dynamic, or as they show on *post mortem* dissection actual structural alterations to the eye or not, the word 'structural' being also very limited in meaning. This division is not only pathological but clinical, and that it is true is seen in the various nomenclatures of insanity which are constantly made. Confusion has arisen from associating together a theoretical or imaginary morbid anatomy, and that which is actually discovered by *post mortem* examination, forgetting that morbid anatomy in our present state of knowledge is almost synonymous with destructive anatomy. All which we recognise is decay and destruction, and if those latter terms were used when we speak of pathological alteration the discussion would be much simplified. It is idle to say that in all cases of insanity, as in all other disturbed functions of the body, there must be some material change in the organs. Every one admits this, and when we say that a diseased mind means a diseased brain, we are uttering a truism founded on no known fact and leading to none. The statement leads to confusion, for it confounds the known with the unknown, and may tempt us to associate under the name of disease two opposite conditions; for the use of the term 'disease' in the general sense is not an expansion of the known, being intended to signify a departure from health in an upward and downward direction, whereas in the precise and known sense it means only a change in the downward direction. In the former or theoretical sense, meaning any departure from health, it might advantageously be discarded from use, whilst it cannot be too distinctly stated that disease of an organ, in our present state of knowledge, signifies destruction of that organ. Morbid changes are destructive changes, and correspond with loss of function. Morbid anatomy has hitherto done little more than show us this. As regards the cerebro-spinal centres, when we speak of disease we mean either the evidence of destruction, or of morbid changes which lead to destruction. This, of course, means loss of function; therefore, whatever our eyes or microscope have hitherto discovered in the brain or spinal cord implies dementia or paralysis, or an approach to these conditions. We should never suspect that there had existed mania, chorea, epilepsy or tetanus; and one cannot well see how symptoms showing an exalted activity, or activity in any

form, could be associated with the destruction of the organ on which the function depends. It may be true that disease in the neighbourhood of the centres, exciting them to over-activity, may be found, but this is not disease of the organs themselves. As regards the brain and spinal cord, Dr. Wilks is not aware that any other changes are known but those which lead to destruction, and are associated with loss of function. All analogies, as well as facts, lead us to think that nothing coming under the denomination of morbid anatomy can be looked for in cases of mania, epilepsy, chorea, and similar affections. If it were not so, and we had any inkling of the peculiar state of the cerebral substance in these diseases, we might know in what manner all our brains differed from the healthy standard; but none of us would expect that the person who was somewhat eccentric in his habits had such a peculiar quality of brain that the eye could discover it, much less that the differences were of that kind which are recognised by the pathological anatomist. If this be so, there is no reason why in another person, whose eccentricity has reached that further stage which obliges him to be secluded in an asylum all his life, the brain should present any morbid peculiarities. To take, therefore, a number of cases in an asylum, and arrange them on a supposed pathological basis, can lead to nothing; the nomenclature should be wholly clinical, and this done, the pathological differences would fall into their right places.

G. FIELDING BLANDFORD, M.D.

MISCELLANY.

THE SELECT COMMITTEE ON ADULTERATION will, we believe, immediately present their report; and it is understood that, notwithstanding the late period of the session, the Government will favour an attempt to procure immediate legislation to remedy some of the defects in the existing Adulteration Act.

THE FLOWER MISSION.—This pleasing method of showing sympathy with those of our fellow-creatures who are less fortunate than ourselves, both in the gifts of fortune and of health, has made its way across the Atlantic. We learn that a number of the most charitable ladies in Cincinnati have associated themselves into a society for the purpose of distributing flowers to the sick poor, in the hospitals and their own homes. Few sick people are insensible to the beauty and fragrance of flowers; and even of those few, but a very small number would not be gratified by this evidence of a desire to in some measure alleviate the pressure of sufferings which, but too frequently, cannot be removed.

THE FRUGAL SWISS.—Many persons will learn with some astonishment that intemperance is as great a scourge in Switzerland as in many other countries. The Swiss are not great smokers, and the quality of their tobacco perhaps does not tempt to the indulgence of the habit, but the consumption of wine in the playground of Europe, and the consequent drunkenness, are said to be enormous. M. Merille de Colleville, corresponding member of the French Temperance Society, asserts on information derived from a medical man in Jura, that the majority of the male population of Switzerland die before they have attained their fiftieth year, from the effects of drunkenness. Statistical returns show that the average consumption per head of the Swiss is sixty litres per annum of wine only; without taking into consideration the cider, beer, and other fermented and distilled liquors which they are in the habit of drinking.

AMUSSAT'S PLAN FOR THE ABLATION OF TUMOURS BY MEANS OF THE THERMIC GALVANO-CAUSTIC PROCESS.—Since 1852, M. Amussat has employed several plans for the ablation of tumours by means of the thermic galvano-cautery. He first pediculated them with steel grooves, also intended to direct the course of the platinum wire; at a later stage he removed them with the galvanic *sécateur*; then with the platinum bistoury. Ablation with the *sécateur* is one of the most simple plans of operation; and the one to which M. Amussat generally has recourse. But when the tumours do not pediculate well, the thread slips, and the section is not satisfactorily performed. To obviate this inconvenience, M. Amussat places one or more ivory stems in the plane of the section, below which he makes the end of the thread pass before introducing them into the *sécateur*, and thus makes certain of the regularity of its action. In the case of a lady who had an ulcerated tumour in the internal portion of the mammary gland, one ivory stem was enough to guide the thread, and allow a very clean section of the tumour, without the least flow of blood. This very simple plan is applicable to tumours of all kinds which do not pediculate sufficiently.

GOOD NEWS FOR BATHERS.—M. Gosselin has invented a new safety swimming apparatus, which has been tried with successful results in Paris. This ingenious apparatus consists principally of an India-rubber pneumatic tube, which, starting from the top of the chest, passes under the left shoulder, down the spine as far as the loins, and then divides into two branches, which are rolled round and round the thighs as far as the knees. Some smaller tubes are joined on to the tube which goes down the back, and meet on the chest, following the lines of the ribs. All these tubes are enclosed in a double casing of flannel, which forms a shirt, buttoning in front. An opening at the upper part of the tube, closed by a copper button, serves to inflate the apparatus. This apparatus can be used for bathing, or in case of shipwreck. It is only necessary to open the aperture at the neck, and to blow into it; the loss of gas is said to be so extremely small that one inflation will last a whole day. To render the apparatus more complete for 'those who go down to the sea in great ships,' M. Gosselin has invented a buoy to accompany the swimming apparatus, which will hold provisions or valuables.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.: free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JULY 8, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

LECTURE UPON THE GENERAL THERAPEUTICS OF THE NERVOUS SYSTEM. BY E. C. SEGUIN, M.D.*

(Concluded from page 399.)

CLASS B.

Means which affect the Substance of the Nervous Centres.

I. Agents increasing action of nervous centres.—Excitants.

By nervous excitants I understand such means and medicines as produce (or can produce) an immediate stimulant effect upon the nervous centres, independently of any corresponding increase in vascularity. The certainty (specificity?) and rapidity of their action distinguish these medicines from tonics.

- | | | |
|-------------------------|---|--|
| A—Cerebral excitants | { | Alcohol, embracing wines, brandies, &c., Cannabis Indica, Belladonna, Opium, Ether, &c., Intellection, Emotional Influences. |
| B—Spinal excitants | { | Strychnia, Brucia, Quinia, Cantharides, Exercise (active and passive). |

A.—CEREBRAL EXCITANTS.—It is very probable that alcohol acts upon the tissue of the brain and superior motor centres, as well as upon the circulation. I have already referred to the dosing of alcoholic drinks, and would only add that for the present purpose small quantities often suffice. In order to secure uniformity in the dosing of alcoholic stimulants, I should be in favour of using diluted alcohol instead of wines or brandy or whiskey. The only obstacles to the adoption of this practice are the prejudice existing against alcohol, and the fact that some stomachs bear wines and beer better than spirit.

Cannabis Indica has been used in cases of melancholia and acute dementia, and in various neuralgic states. Its specific effect is to excite the imagination. A sort of delirium is produced which, in most cases, is not accompanied by absolute unconsciousness, although the patient has the most extraordinary fancies, hallucinations, and delusions. It is this power of stimulating the imagination which has placed it among the remedies to be administered in apathetic cases. The success of the remedy, however, has not quite equalled the anticipations of theory. In cases of cerebro-spinal malnutrition (migraine, etc.) its influence is beneficial.

Belladonna and opium are both stimulating to the brain when given in small doses, increasing intellection and producing hallucinations. When given in large doses they produce, besides, an after-effect of depression. It is only upon some few individuals that this peculiar effect of belladonna is manifested;

and many patients can take this remedy for a long time without complaining of any hallucinations or excitation of the imagination.

One of the dangers of administering opium is the temptation to continued indulgence in the use of the remedy for the sake of the intoxication which it produces. I would ask you always to bear this danger in mind, and to consider the responsibility attaching to the giving of opium as not ended until you are satisfied that your patient no longer uses the medicine. After treating a neuralgia, or other painful affection, with opium internally, or with hypodermic injections, you are to withdraw the narcotic very gradually—to wean your patient, as it were. I cannot conceive of a much greater cause of sorrow for a medical man, than to have been the cause of the enslaving of a human being by the opium habit.

Ether produces intoxication which is often very violent, when given by inhalation for purposes of anæsthesia. It is not ordinarily employed as a cerebral excitant.

Emotional excitement is not sufficiently employed as a means for affecting the nervous centres. It is seldom applicable where organic disease is present, but is more especially indicated where the mind is absorbed in contemplation of delusions, and in hypochondriacal and hysterical cases.

Cases of hysterical paralysis have been cured by an alarm of fire, or some other immediate danger. The pleasurable emotion of hope is very powerful, and its use makes possible the success of various quackish methods. In legitimate practice, we should, I think, make greater use (within the bounds of truthfulness) of the potent emotions of hope and faith.

Many cases of melancholia have been benefited in a remarkable manner by getting them interested in some matter, either of love, or affection, or emulation. There are patients who have a certain amount of dementia, produced by the presence of some convulsive disease, such as epilepsy, chorea, &c. In these cases intellectual exercise is to be recommended and insisted upon: some intellectual excitement should be daily enforced.

B.—SPINAL EXCITANTS.—Nux vomica, strychnia, and brucia are medicines which affect in an almost specific manner the motor parts of the spinal axis, stimulating it primarily. The result of over-doses of these remedies is spasm of muscles supplied by spinal nerves. In small doses these drugs act upon the same parts slowly, and improve their nutrition. The indication for the use of strychnia, etc., is the existence of simple exhaustion of the nervous centres, of spasm due to weakness and anæmia, of paralysis (inhibitory or reflex) not due to inflammation of the spinal centre.

We also make use of these remedies in some cases of functional nervous disorders. They are beneficial in cases of chorea and epilepsy, the morbid states grouped together under the name of 'spinal irritation.' In many of these cases the remedy (strychnia) should be given in the manner long ago pointed out by Brown-Séquard, that is, in doses necessary to obtain its physiological effects.

Bearing in mind that females are much more susceptible to the influence of these drugs than males, you should commence the giving of strychnia by doses of 1-40 or 1-32 grain, increasing rapidly to 1-16 or 1-12 grain three times a day for adults. There is not the same ratio of susceptibility to the influence of this remedy, with regard to age, as is seen in con-

* From *The New York Medical Record*.

nection with opium and some other remedies, children bearing large doses well. Nux vomica may be administered in 1-4 or 1-3 grain doses thrice a day, and the doses may be progressively increased.

It is better to use strychnia in solution. If it be given in pill, you will run the risk of the drug not having been carefully divided in the preparation of the pills; and the additional danger, which is much more likely to happen, that the pills will not be dissolved in the alimentary canal until an accumulation of them has taken place, which will develop results most undesirable. The necessity of using an acid to properly effect a solution of strychnia permits us to use diluted phosphoric acid, which is itself a serviceable remedy in the treatment of nervous affections; or we may use the various acid phosphates which are now offered to us in elegant preparations by druggists.

In cases of paralysis strychnia may be used hypodermically, with benefit, 1-40 to 1-10 grain being injected once a day, or once every other day. For this purpose I would recommend Barwell's solution at half strength, one minim of which contains 1-50 grain of strychnia.

Quinia sometimes acts in a manner which entitles it to a place in this class of remedies. There has been considerable doubt as to whether quinia affects the nervous system at all. There are, however, good reasons for believing that the phenomena of intermittent fever are of spinal origin. Quinia cures all forms of this disease almost with certainty. Another reason for believing that quinia affects the nervous centres is the fact that its administration aggravates spinal disease. According to Brown-Séquard, it acts as a poison to epileptics, and this effect will allow of only one explanation, namely, that the motor centres concerned in the production of the paroxysm are excited and rendered more susceptible by this remedy. Lastly, we have the general tonic effects of quinia, which cannot be denied. Quinia will also stimulate the cerebrum, as is shown by the fact that intellectual exertion is more easy and free after its use. Dr. W. H. Draper, of this city, has given small doses of the medicine to two well-known clergymen, with the result of restoring their power of extemporaneous speaking.

Cantharides excites the spinal cord, and seems to act more particularly upon its lower portion, manifesting its action by the development of symptoms especially connected with the genito-urinary apparatus. It is useful in cases of bladder paresis, of impotency, or simple genital inertia.

Exercise, both active and passive, is indicated in conditions of paralysis or paresis, or in simple spinal debility. Much of the passive exercise we make use of is obtained by means of electricity, which will be separately considered. Exercise should never be pushed to exhaustion; and I would have you bear in mind that exertion more easily produces exhaustion in the subjects of nervous diseases, and in the insane especially.

LOSSEN ON THE MECHANISM OF HERNIAL STRANGULATION.

Dr. Hermann Lossen (*Centralblatt für Chirurgie*, no. 4, 1874) states, that 'for the reduction of those cases of hernia in which, from inflammatory swelling, a protruding intestine has so much increased in volume that it cannot be pressed back through the

same aperture by which it protruded, there exist two rival theories. Roser's valve theory, and Scarpa and Busch's theory of pinching of the intestinal canal. To decide whether either of these be correct, and if so, which is the more so, I repeated Busch's experiments with fresh pig's gut; but, instead of water, I used melted wax which, on cooling, became a solid mass. The hernial apertures were represented by holes bored through the lid of a cigar box, through which a finger might pass. The casts of the loops after removal of the artificial hernial rings were now embedded in wax of another colour, and vertical sections made through them. In the same fashion a number of loops inflated with air were artificially strangulated and then dried.'

The following results are demonstrated by these preparations and experiments.

1. At the moment when the wax, or air, or, in the living gut, the faecal matter, enters the afferent end, the efferent portion of the gut, at the level of the hernial aperture, is pressed together, and by the constantly increasing pressure is finally completely closed.

2. This being accomplished, no pressure, however great, coming from above, will re-open the distal end of the gut.

3. The pinching (*Abknickung*) of the intestine, which is principally referred to the opposed folds of mesentery, is not the cause, but the consequence, of this closure.

4. The afferent end is never closed, which appears to contradict the hydrostatic law that in a closed space lateral pressure acts equally in all directions, and perpendicularly to the surface. According to this law, the pressure in a strangulated loop must exist up to the level of the hernial ring; and above it, in the afferent piece of intestine, a diminution or increase of pressure must manifest itself equally in all directions.

This may be demonstrated with extreme facility by means of a manometer attached to the afferent end of the artificially incarcerated loop of intestine. It may be shown in this manner, beyond all doubt, that in the living intestine the whole column of excrement presses upon the contents of the bowel in the strangulated loop. Therefore the pressure on the sides of the loop will depend upon the height and length of this column, and upon the resistance the intestine offers to the pushing back of the faecal contents. The height of this column may become considerable by reason of the long continuance of the strangulation. During this time the pressure constantly augments, but it possibly may be reduced by severe faecal vomiting. The impediments arising from friction are the most important. These, from the very outset, are in inverse proportion to the transverse section of the hernial aperture; they depend further upon the viscosity of the contents of the bowel, upon the number of 'pinchings' of the intestine occasioned by the gradual swelling of the convolutions of the bowel above, and also upon the contractile force of the pylorus and of the ileo-caecal valve. They increase with the increasing peristaltic motion and swelling of the intestinal coverings, in consequence of which the afferent end may ultimately assume the minimum transverse section.

The author's observations and experiments show how great the lateral pressure upon the loop may become. It is manifest that the maximum of lateral pressure immediately above the hernial aperture must be attained at the time when that pressure equals the sum of the resistance due to impediments in the

whole upper tract of the bowel. From this moment must commence a backward motion of the contents of the bowel, the fluid particles flowing back in the axis of the canal, whilst along the walls the peristaltic influence will urge the matter forward. In the strangulated loop these movements are reversed, and maintain the equipoise. Under these circumstances the pressure does not further increase.

In the living subject the resistance is much greater than in the dead, in consequence of the peristaltic action, the viscid nature of the bowel contents, and the smaller size of the hernial aperture.

The manometer shows that all species of direct pressure upon the tumour increases the tension, and aggravates rather than improves the condition of affairs. Neither Roser's nor Busch's theory explains this. It is the lateral pressure at the orifice of the sac which alone prevents reposition.

A rational taxis then will renounce attempting any alteration at the afferent end. The efferent end is the one to be opened. This is to be effected, Dr. Lossen says, as I am in a position by the manometric experiment to prove, by pressing the loop of intestine towards the side of the afferent end. The efferent end is by this means opened, and the loop partially empties itself, then a slight pressure upon the hernial swelling is sufficient to effect reduction.

Seeing that no practical diagnostic means are known whereby it can be accurately ascertained at what side, the right or left, the upper or lower, the efferent end may lie, the author recommends that sideward movements of the hernial swelling be carried circularly round. If this end be not attainable, an external herniotomy may be made, and then similar manipulations again tried before incision of the ring.

From the preceding it is also clear that, in the internal treatment, laxatives must not be administered, and that large doses of opium are to be commended immediately after the occurrence of strangulation. The peristaltic action will be thereby lessened, and thus one provocative of lateral pressure eliminated.

[The reporter had the gratification of seeing Dr. Lossen's striking and conclusive experiments at the late Surgical Congress in Berlin, and he has since repeated some of them himself. The attempt to draw down a strangulated hernia, which is sometimes successful in effecting reduction, probably is so by thus opening up the distal end of the strangulated loop. The experiments of Dr. Lossen are simple, and easy of execution by anybody who will procure a piece of intestine, cut a half-inch round hole in a cigar-box, and provide himself with the means of inflating the gut with air or fluid. The subject is one of very great interest.—*Rep.*]

WILLIAM MAC CORMAC.

BROWN-SÉQUARD ON THE CEREBRAL POWER IN MAN.

The last Tonar Lecture was delivered by Dr. Brown-Séquard, at Washington, April 22.

According to the report in the *Medical and Surgical Reporter*, he commenced by saying that he hoped that his views, being somewhat novel, would command attention. The facts on which he would dwell were new, probably would not be generally accepted, and, perhaps, would not be easily understood by those not familiar with medicine.

Have we two brains? and, if so, why not educate both? The views of science upon this subject were different from his. The left side of the body was the side affording volition to the brain, and, *vice versa*, the right side of the brain afforded volition to the body. Eminent authorities had declared that either side of the brain was competent for this purpose. But we use only one side, and, therefore, leave out of account one-half of brain-matter. We owe due education to both sides of the brain, or rather, to the two brains.

As to intelligence, the eminent authorities he had cited established the fact that either side of the brain was competent for full development of the faculties. There were many persons of two minds, because they were never able to make up their minds. Some men claimed to be rational while they were insane. There were many cases that showed clearly that there were two brains. He had known a boy in London that manifestly had two brains, whose peculiarities he described. He would fall into a comatose state, and suddenly open his eyes brightly, inquiring of his mother why he was not introduced to the gentleman who was present while he was asleep. Again, the lecturer saw him when the boy recognised him. He had two mental lives. He knew nothing of what occurred in his sleeping condition, when fully awake; and when in the latter condition he knew what had occurred when in the former. The lecturer had seen three cases of this kind.

As regards faculty of speech, the fact that we had two brains was not so easily proved. The loss of the faculty of expression depends upon disease of the left side of the brain; and this proves that the right side is distinct.

As regards sight, a theory has been put forth by a celebrated physician of London, that the right side of the base of the brain is the centre of sight. The inner half of the right eye and the outer half of the left eye have the base of the brain as the centre. A disease in the left side of the brain, where the optic nerve touches, would, therefore, affect only one-half of the brain. Notable cases were given in which parties had seen but one-half of certain objects that they gazed upon. If the disease exist only in the left side of the base of the brain, only one-half of the eye will be affected. So there are many cases that go to sustain the philosophers. But we do not accept conclusions unless theory be thoroughly supported.

There were three series of facts, but one would be enough to show that the theory should be rejected. Disease of the brain, where the optic nerve touches, would not be sufficient to cause loss of sight. One side of the brain would be sufficient to sustain sight. An alteration in any portion of the nervous system, acting upon other parts, can produce disease in that part. Injury to the spinal cord would produce loss of sight on either side. There was nothing more common than the loss of sight temporarily in children who suffered from worms in the stomach. An injury in one-half of the brain can exist without producing loss of sight. Either half of the brain may, therefore, serve to sustain sight.

As to the voluntary movements, these depended upon the action of the body. Yet there were many small muscles which were not affected in cases of paralysis. There were cases on record in which it was shown that the lower lobe of the brain could be destroyed without affecting these voluntary movements. There were several such cases. We must, therefore, look on one-half of the brain as being

sufficient to sustain voluntary movements on both sides of the body. An irritation in any part of the brain may affect any part of the body, and an irritation in any part of the body can produce paralysis in another part. The irritation could also act upon remote parts. This shows that the power of will does not control the entire action of the body. When paralysis occurs, it depends upon irritation.

The same reasoning applies to sensation. There were thousands of cases affecting the brain that did not affect the feeling. Passing these facts in review, we find vast differences owing to the fact that one-half of the brain was developed for certain things, and the other half for other things. To the left side of the brain belonged the faculty of expressing ourselves by speech. Articulation depended in great measure upon the left side of the brain. Difficulties in the mechanical point of speech were more frequently found when the left side of the brain was diseased. It was the mental part that was lost, and not the mere mechanical action. The left side of the brain was also the motive power of gesture. When the left side was diseased, patients lost the power of gesticulation.

As regards writing, it was lost more frequently in diseases of the left side of the brain. The right arm was paralysed by diseases of this side. Many thus diseased could not write from memory, although they could use their fingers and copy. In those cases, it sometimes occurred that persons could not write at all.

Intelligence depends more upon the healthfulness of the left side than of the right side of the brain. The right side of the brain in some cases has the power of the left, if properly developed. This serves to hysterical developments, and to nutrition of the body. One, the left, applies to mental; the other, to the natural life.

The right side of the brain operates upon the limbs in cases of paralysis and other diseases; also upon disturbances in the lungs, liver, and other parts. Hysterical and emotional symptoms are more common in cases of disease of the right side of the brain; out of 120 cases of paralysis that came under the lecturer's observation, there were 96 caused by disease of the right side. An alteration of the retina of the eye will come more frequently from diseases of this side of the brain. Out of 69 cases of convulsions of the eye, 47 were due to disease of the right side. Death occurs much more frequently by disease of the right side of the brain, and in cases where patients do not die it will produce more extensive and enduring paralysis.

All this shows, not that the two sides of the brain differed originally, but that there were different developments of each. The left side of the brain was much larger than the right side. If a person went frequently to the same hatter he would find that his hat had from time to time to be enlarged. There was no question that the brain grew. By studying a particular subject the person became more proficient, and the brain was more fully developed.

There was no doubt that the left side of the brain predominated in our system. Our being right-handed showed it. There was no population in the world that was not right-handed. The right hand of the body was mostly used. Left-handed individuals used the right side of the brain, showing the connection between these things.

There was primitively a difference between the two brains. In children, convulsions were sooner de-

veloped in the left than in the right side of the brain. This was attributable to excess of blood in the left side. Parrots roosted on the right legs, and their talking power came from the left side of the head.

There were four vital points to be considered. The first was that asphyxia was connected with the left side of the brain in persons that were right-handed, and with the right side in those that were left-handed. The second point was that children who were first learning to talk, if disease came in the left side of the brain, learned to talk just as well with the right side of the brain. Though losing half the brain, they got along just as well.

This proved that the right side could be educated, with the left hand for execution. The third point was, that four out of every hundred left-handed persons learned to write with the left hand; therefore, the left side of the brain, even with persons left-handed, could be educated better than the right side. The fourth point was that the leg was rarely so much affected by paralysis as the arm. He, however, would pass over this argument, as it could only be understood by medical men.

If the lecturer had established that we had two brains, then they should be developed. If we could develop the legs and the arms of both sides, we could develop both sides of the brain. If we gave as much attention to the left side of the body as we do to the right side, we would fully develop our two brains. The important point, therefore, would be to make children use both sides of the body—alternately using the right and left arm and the right and left leg equally. There would be no difficulty in thus training children to full development.

Even adults who had lost speech by disease of the left side of the brain could regain the power by cultivating the right side. In gesture, persons who had lost the use of the right arm could be trained to use the left. If children were thus trained, we would have a sturdier and healthier race, both mentally and physically.

EPIDEMICS OF CHOLERA IN FRANCE.

Apropos of the present sittings of the International Sanitary Conference, we take from the *Medico-Chirurgical Review* an excellent although rather long *résumé* of the Report on Epidemics of Cholera in France,* in 1832, 1849, 1855, and 1865.

The Academy of Medicine having appointed a committee of its members to investigate cholera, a number of reports were submitted to that committee on the epidemics which at various times have visited the country. From them an able report was drawn up by M. Barth; but for our present purpose it will be sufficient to notice only some of the conclusions at which an endeavour has been made to arrive—for it must be confessed that few, if any, have actually been reached.

France has been visited by four great epidemics of cholera, besides some partial explosions, which seem to have been appendices to them. Thus there were, (1) the epidemic of 1832, followed by a short re-appearance, in 1834, on the shores of the Mediterranean; (2) that of 1849; (3) that of 1854, which began in November, 1853, finished in January, but

* *Rapport sur les Épidémies du Choléra-Morbus qui ont régnés en France pendant les années 1854 et 1855.* Par M. Barth, au nom d'un Commission, &c. &c. Paris: P. Masson, Éditeur, 17, Place de l'École de Médecine, 1874.

recurred in March following, and did not disappear till 1855; and (4) that of 1865, which broke out in June, and continued throughout that year and the following, not disappearing till 1867.

With regard to direction, those of 1832, 1849, and 1854 invaded the north of France, advanced westward, ending in the department farthest in that direction. That of 1865, on the contrary, appeared on the French shores of the Mediterranean, extended northwards, and reached the remote parts of Brittany and Normandy. The epidemic of 1832 broke out in Paris with great violence in the latter days of March, ravaged several districts like a hurricane, attacked in succession 56 departments, ending the same year, after destroying 110,000 to 120,000 persons. That of 1849 also appeared in the end of March. It for a time was restricted to the parts immediately around Paris. It then attacked the city with a violence hardly less than that of 1832; ravaged 57 departments, and disappeared before the end of the year, having caused 100,000 to 110,000 deaths. The epidemic of 1854, on the contrary, began at the end of October, 1853, appeared to diminish soon afterwards, rekindled in March, having Paris for its principal theatre. Thence it extended over 70 departments, and ended the following year, after having destroyed more than 140,000 victims. That of 1865 appeared in June, prevailed for some time at Marseilles and Toulon; some months afterwards it appeared in Paris, where it lighted up in the following summer, causing at the same time cruel ravages in Amiens. It continued throughout the winter in the north-east of France, and was not extinguished till the end of 1867, having visited fewer departments and caused much less mortality than either of the preceding epidemics. Thus, while the epidemic of 1854 had a shorter period of duration, and caused more victims than either of the two preceding invasions, that of 1865, slower in the progress of its movement, continued longer, yet caused less mortality than either of the others.

In the two first epidemics the northern part of France principally suffered. Of 56 departments invaded in 1832, 52 only were so also in 1849. In 1854 the epidemic had a greater extent; it produced great mortality in Paris, and stretched thence to the Alps and the shores of the Mediterranean. Of 70 departments invaded by it, 54 had been previously ravaged by one or two epidemics, and of 16 respected in 1854, six had been previously visited by the disease. At the end of that year only nine departments had remained unvisited during the several epidemics. Of these one was slightly visited in 1855; the eight others preserved their immunity during the invasion of 1865-6. Thus, certain regions were visited by all the epidemics; others were visited by one or more, while a few have continued exempt from all. As a rule, the districts most spared were those in the centre of France, and most elevated above sea level; on the contrary, those most densely inhabited and of inconsiderable elevation, suffered most. In this, however, there is nothing either absolute or constant. Thus, in 1854, the epidemic was in sixteen departments more fatal than in that of the Seine. Amiens, previously spared, suffered greatly in 1866; Rouen was exempted in 1854, and Lyons was only slightly visited by any of the epidemics. For a time explanation of this relative immunity was believed to exist in conditions connected with the nature of the soil. The exemption of the regions in the north-east, in 1832 and 1839, was attributed to

the existence of sandstone of the Vosges; yet that region was mostly dealt with in 1854. In a similar manner, parts of an arrondissement or canton spared at one time, have been ravaged at another; while others, ravaged by the early epidemics, were exempted by subsequent ones, although they continued to rage around them.

In some places the epidemics of 1854 and 1865 were more distinctly preceded by derangement of the intestines than those of 1849 and 1832. Such derangement was by one set of observers looked upon as premonitory of the epidemic; by others, as independent of it, and only proceeding from ordinary causes incidental to the heat of summer; by some, as due to fear of the epidemic. In many localities, however, the epidemic suddenly appeared while the state of the public health had till then remained satisfactory.

In all the epidemics the disease showed itself in the forms of cholera and confirmed cholera. The affection becoming developed in a person arriving in a healthy district from one infected, seemed to have a period of incubation, varying in length from one to four days. Whether in the form of cholera or cholera, the attack for the most part occurred at night; this circumstance being variously attributed to the process of digestion after a heavy meal, to the body being at rest, and to the non-renewal of fresh air around the person. Sometimes the attack was sudden and severe, death taking place in a few hours; more frequently it was slower, being preceded during some hours or days by diarrhoea,—an indication of great importance when it does occur, as treatment employed in this stage often checks the further development of the disease, and consequent mortality by it. Diarrhoea is so constant a symptom, that its absence, recorded by some authors in cases of what they called *dry cholera*, is denied by the majority, or looked upon as an error of diagnosis. For the most part it is the principal indication of the disease, and that which first appears; being followed in their turn by vomiting, cramps, cyanosis, failing of the pulse, coldness of the extremities, alteration of the voice, and suppression of urine. All these indications characterise the several epidemics, presenting only some slight modifications here and there, as less abundant dejections, less violence of cramps, less cyanosis, and so on. In the epidemic of 1854, the dejections contained more lumbrici than in any of the others, these entozoa, besides being thus evacuated, appearing sometimes in the matters vomited. The appearance of characteristic complications seemed less sudden in the epidemics of 1854 and 1865, in some places, than in those preceding; in others they were more so, and progress of the disease to death in many more rapid. In some marshy districts the disease presented some characters of intermittence more or less marked. In some instances, in all epidemics, the disease did not advance beyond the state of cholera, convalescence more or less rapid taking place from it. In other instances diarrhoea, nausea or vomiting, cramps, and the other characteristic symptoms, were present in inconsiderable severity (*cholera léger*); but more frequently there were repeated evacuations of serous fluid, succeeded by violent and painful cramps, great coldness, alteration of expression, voice sunken, and pulse imperceptible (*cholera grave*), but between these extremes there were intermediate cases, having neither the moderation of the first group nor the intensity of the second (*cholera moyen*). For the most part death took place in the algid stage; often,

however, where treatment was early employed, reaction was obtained, characterised by diminution of the evacuations, cessation of vomiting, appeasement of cramps, re-establishment of the pulse, and return of warmth. This reaction, when excessive, gave place to congestions of the encephalon and lungs, followed by prostration and stupor, designated a typhoid state. In these respects the epidemics of 1854 and 1866 presented similar characters to the two preceding, with merely slight modifications. In the two latter, papular and erythematous symptoms, diphtherite and swelling of the parotids, were more frequent than in the former, and further, a diminution in the number of attacks and deaths by ordinary diseases was observed during the last two epidemics. In 1854 an exception to this occurred in regard to the prevalence of *sudamina*, or sweating sickness. It continued on that occasion to affect one set of patients, while cholera attacked another, the two diseases appearing to run their course independent of each other. In some instances, however, they succeeded each other in the same individual; the occurrence of *suetie* at times seeming as preparatory of cholera, in others, seeming to act as a preservative against it. In all the epidemics, relapses and the occurrence of sequelæ of the disease were observed. In some instances, persons who had been affected in one or both the epidemics of 1832 and 1849, escaped in 1854; others were attacked in each of the epidemics which occurred, and some who had recovered on the two earlier occasions were carried off in 1854.

The duration of the disease in the several epidemics was very various. As a rule, it was of shortest duration in the early period of an epidemic, the patients often dying in eight or ten hours. In the most part, however, they succumbed in thirty-six hours to two days in the algide stage, or at a later period their reaction and the typhoid state set in. Excepting slight cases, recovery did not take place completely in less time than a few days. In the greater number of instances, especially if attended by reaction, it did not take place in less than two weeks; often convalescence was slow, being accompanied by persistent debility. Frequently the occurrence of cholera causes the death of the fœtus *in utero*, and induces abortion. In a few cases abdominal dropsy has disappeared after an attack of the disease.

In all the epidemics, it was observed that cadaveric rigidity set in early. In some exceptional cases certain movements of contraction and extension in the limbs occurred after death. The anatomical changes did not vary during the various epidemics. The isolated follicles of the intestine were exaggerated; the heart and vessels contained ropy black blood; there was more or less injection of the mucous membrane of the digestive tube, suffusion of the lungs; vascularity of the pia mater and mucous centres in cases of death after reaction. These are the appearances found in all seasons, and in all latitudes.

On the subject of etiology, it is observed that cholera has visited regions the most diverse—continents and islands—all latitudes, from the equator to the polar circle—climates the most diverse, and elevations above snow level. With regard to France, it has prevailed in all seasons, temperatures, and barometric conditions—in dry weather and in wet—under electric conditions the most diverse, and in all conditions of the wind. From the reports received, however, it is clear that a high temperature is favour-

able to the development and increase of the disease, it being during the hot season that the attacks are most numerous, and in the cold that they are less so. According to the reports of 1854, great and violent atmospheric perturbations, as hurricanes and sudden variations of temperature, are often followed by an increase in the number of attacks and deaths by cholera. The wind seems to exert an influence as an agent of propagation of cholera at a short distance, and places fully exposed have been found more severely affected by the epidemics than others that were more sheltered. In France the disease prevailed throughout the four arrondissements, at altitudes the most diverse, including the mountains of the Vosges, Jura, Alps, and Pyrenees, and on the plains that border the Mediterranean. It has prevailed in districts of different geological formations, including primitive, secondary, and recent; on the sides of hills, and in valleys, plateaux, and plains; bare and wooded districts; waste and cultivated; upon dry soils and upon humid; sandy, gravelly, and clayey; chalky and marshy: quartz, sandstone, and granite; in districts the most healthy, and in those that are unhealthy. As a general rule, however, it is observed that low situated localities, and those that are marshy, are especially favourable to the development and spread the disease, and that such as are elevated and naturally healthy, afford comparatively the greatest security.

As no kind of locality remained free from the disease, so no class of persons were exempt. All social grades and positions suffered from it. In some places, even where the hygienic and social conditions seemed most favourable, the rich and well-to-do suffered the most severely; nevertheless, the result of careful analysis has been to show that cholera has prevailed most where the hygienic conditions have been bad;—that want of air, crowding, insufficient clothing or warmth, fatigue, bad food and privation, all conduce to it; also, that depressing moral influences have the same effect. In addition to these, the development of the epidemic is favoured by the occurrence of inundations during the hot weather, contamination of the water, vitiation of the air by telluric and fetid emanations of various kinds, great agglomerations of people, and in fact, all violations of hygienic laws. Several reports specially indicate the liability to attack of such as are employed in attendance upon the infected, as also of those who have to deal with and wash the linen used by them, and with the interment of the dead. No age was exempt from attack; yet the two extremes of age and youth furnished the largest proportion of deaths. The weak and enfeebled offered least resistance to attack; yet the strong and robust were in no way exempt from it. Those suffering from chronic diarrhœa, from phthisis, and such as were convalescent, seemed also to be peculiarly exposed to it. There appeared, moreover, to exist an individual predisposition to attack; and it is remarked, in regard to the epidemic of 1854, that this predisposition was traced in numbers by consanguinity of the same family, rather than among such as were only related by marriage.

Various opinions have been expressed in regard to the nature of the disease. It has been considered to consist of a species of intermittent fever, an affection of the ganglionic system, a variety of typhus, a disease of the liver, a special fermentation, a new disease *sui generis*, the cause being according to some unknown, according to others, existing in conditions which

induce sporadic cases of cholera, and these becoming more general and intense, affect the masses in the form of an epidemic. Others look upon it as consisting of a miasmatic poisoning, of an unknown nature, affecting the nervous system, of organic life, or the blood, and entering the system by the pulmonary or digestive canals. This uncertainty in regard to the nature of cholera is reflected in the different opinions expressed as to its propagation. According to some authors, the disease springs up, is developed and multiplied, in a given locality under the influence of various morbid causes, becoming fatal by their accidental co-existence. Others add to the presence of insanitary conditions, the concurrence of accidental causes, such as modification of the air by the existence of diseases of the vegetable kingdom, and general debility arising from deterioration of alimentary substances. Some consider that it is imported by persons arriving from an infected locality, that the disease becomes multiplied and developed, and communicable from one to another by *mediate* contagion in the same way that typhus does. This theory, generally denied in 1832, was more frequently brought forward in 1847, and in 1854 became predominant,—sixty-one out of ninety-seven authors who allude to it expressing their opinion that cholera is thus transmitted.

In 1865 the opinions in favour of the importation and mediate contagion of cholera became still more general. It had appeared at Mecca immediately after the arrival at that place of a caravan of pilgrims from India; it increased in an atmosphere rendered pestiferous by the presence of thousands of putrefying dead bodies; it broke out at Cairo and Alexandria with the return to those places of the pilgrims; it invaded afterwards Constantinople, then Mocha, Barcelona, and Marseilles,—these being the ports between which and Alexandria communication was most frequent; and while it extended in other directions, Sicily, at which no vessel touched, escaped. At the same time, attention being awakened, it was easy to follow the track of successive explosions, and to trace with certainty the transmission of the disease from one individual to another.

Methods of treatment the most various were employed. Bleeding used in 1832, was less frequently had recourse to in 1849. In 1854 it was used against complications, as secondary fever; but in 1865 was too much forgotten from the tendency there is to pass from one extreme to another. Opium, vaunted by one set of authors, was condemned by another, so also with ipecacuanha. Evacuants, praised by some, were declared by others to be deadly. Antispasmodics, notably ether and chloroform, were generally employed with advantage against spasmodic phenomena. Frictions and excitants to the surface were used, but opinions in regard to them seem to be unrecorded, and a similar remark holds good in regard to the employment of cold. Quinine, generally without success in the algide stage, was a little more efficacious during secondary fever. Sulphate of strychnine and nuxvomica were either followed by want of success or by distinctly unfavourable results, and the same is said of valerianate of zinc. Sulphate of copper, reported on favourably in one place, was condemned in others. Without enumerating many other remedies, homœopathy was employed in many places. At Dienville, of sixteen cases thus treated fourteen died; and at Marseilles, in 1854, out of twenty-six similarly treated, twenty-one died. It is added that

where success followed remedies it was mainly due to the hygienic care, particularly to the means taken to keep up the temperature of the body. Some writers disbelieve in the power of medicine during the algide stage, observing that the function of absorption is then destroyed. Indeed, whatever methods were adopted in the epidemics of 1854 and 1865 the results were equally unfortunate as in the two preceding, namely, 50 per cent. of the patients died. When the rate of mortality is only one-third of those attacked, the results must be considered satisfactory, and when under that, as exceptional; in fact, statistics showing a smaller death-rate are open to mistrust. The manner of preparing statistics varies also; some writers include all cases, whether severe or slight, even simple diarrhœa, thus showing very favourable results, even when actual success is the reverse. Different degrees of strength in patients themselves also influence the rates of mortality. As a rule, an epidemic is more severe at its commencement, and less so in its decline; more fatal in infancy and old age; less so in youth and mid age; more limited in civil life, where patients are isolated; more fatal in hospitals, where it attacks organisms already debilitated, and where cases of the most severe nature are taken.

According to the majority of writers, the principal cause of mortality is the too frequent neglect of the early symptoms, and delay in employing treatment. Nearly all insist upon the necessity to combat the disease at its origin. A great many writers place preventive treatment, even before the curative, and only see safety in the application of hygiene to preserve persons and localities threatened by the disease. These measures consist, for the individual, of temperance, and care to avoid fatigue and excess of all kinds; for the inhabitants, cleanliness, renewal of air and ventilation, disinfection of threatened houses, and especially of such as have been attacked; the removal of dejections, the disinfection of matters and linen soiled by excretions, and the prompt interment of the dead. The wards of hospitals ought to be fumigated, and chlorides sprinkled in public places. Some reports suggest the disinfection of the atmosphere, either by fires of oil or by means of blasting-powder, and in confirmation state that in the village of Thiénant the epidemic suddenly disappeared after the occurrence of a fire, which consumed several houses. House-to-house visits, for the purpose of early discovering persons attacked, are recommended. The committee observes, with regard to these measures, that although all are very proper, yet, would it not be better to strangle the evil at its primary source, or, at any rate, to prevent it from reaching the country?

ANATOMY AND PHYSIOLOGY.

BOEHM AND OTHERS ON THE PHYSIOLOGICAL ACTION OF ARSENIUS ACID.—Professor Boehm of Dorpat records in the *Archiv für Experimentelle Pathologie und Pharmacologie*, vol. ii. Heft 2, his own researches and those of his pupils, on the physiological action of arsenious acid. The experiments were conducted by S. Unterberger upon cats and dogs. On injection of a watery solution of arsenious acid into a vein, a gradual sinking of the mean blood-pressure occurs. The amount of sinking is in direct relation to the quantity

of arsenic employed. This sinking is never preceded by an increase of the blood-pressure, and is only temporary when it owes its origin to small doses (0.005 to 0.03 grammes). At the same time, the pulse is rendered slow. These phenomena can be ascribed partly to paralysis of the abdominal blood-vessels, and partly to a diminution of the capacity of the cardiac muscles for action. The cardiac nerves in animals poisoned with arsenic exhibit normal relations. The vessels of the sympathetic areas are not paralysed by the poison.

The action of this drug upon the intestinal canal was also studied. To arsenious acid is generally ascribed a local irritating action. The chemical reason for this irritating action is quite unknown. This substance exhibits no special affinity either for water or for albuminous bodies. The action of this drug was studied in similar animals (dogs of the same size, age, weight, &c.) and its effects contrasted according as it was introduced by the mouth or by injection in solution into the circulation. When one has before him two similar animals which have been poisoned with arsenic, it is impossible from the *post mortem* appearance to say which of the two animals has received the poison by the stomach or through the blood. Not only so, but the phenomena during life are similar, and the only difference is that the smallest lethal doses when given by the mouth, are not sufficient to kill a similar animal when injected into a vein; and that in the latter mode of poisoning, death always occurs somewhat later than in poisoning through the stomach.

After death, no matter how the poison was introduced, the mucous membrane of the stomach throughout its whole extent was tinged dark red, was considerably swollen, and presented a velvety appearance. The redness was always confined to the most superficial layers of the mucous membrane. In the serous membrane of the stomach, beyond a very pronounced filling of the vessels, numerous large ecchymoses were generally present; loss of the substance of the mucous membrane was never observed. The degeneration of the gastric glands, described by other authors in the rabbit, were not found. Essentially different was the appearance throughout the whole length of the intestinal canal. The mucous membrane was covered throughout its entire extent by a yellow-coloured, jelly-like, but still consistent membrane about one millimetre thick. Microscopically, this membrane appeared to consist of innumerable pus-cells, embedded in a structureless material. This membrane could be removed, when the mucous coat was exposed, generally filled with small point-like ecchymoses. The villi were greatly swollen, and were devoid of epithelium over their entire surface, and numerous pus-like cells were also embedded in their substance. In the other organs, nothing remarkable was found. The liver and kidneys had never undergone fatty degeneration. Ecchymoses in the endocardium of the left ventricle were constant, often also in the other serous membranes. These results are not favourable to the assumption of a local irritating action of the poison. The authors hold as unexplained the action of arsenic on the gastro-intestinal tract. Schmiedeberg remarks the resemblance of the action of sepsin to that of arsenic, in that the former exhibits no local action. In the intestine, only traces of arsenic were found on analysis of its contents by the Marsh method.

GÖRZ ON NATIVELLE'S DIGITALIS PREPARATIONS
IN THEIR CHEMICAL AND PHYSIOLOGICAL RELA-

TIONS.—Dr. N. Görz (*Archiv für Experimentelle Pathologie und Pharmacologie*, Band ii.) has prepared the three chief constituents of digitalis leaves after Nativelle's method, and studied these substances in their physiological relations. These three preparations are the crystallised digitalin, the amorphous (soluble in water) digitalein, and the crystalline digitin. The two former are the physiologically active principles, whilst digitin is quite inert. Digitalin could not be obtained in sufficient quantities for experiment. From 3,000 grammes of dried digitalis leaves, 1,298 grammes of pure dry digitalein were obtained. This substance is obtained by precipitating it with tannic acid from a watery solution. The precipitate is then treated with mercuric oxide, extracted with strong alcohol and evaporated over a water-bath.

Digitalein is a light yellow, almost colourless non-hygroscopic powder, with an aromatic odour and exceedingly bitter taste. When applied to the Schneiderian mucous membrane or conjunctiva, it produces a strong burning sensation and increased secretion. It is easily soluble in cold and warm water and alcohol; benzoin and chloroform dissolve only a trace of it, and when pure it is insoluble in ether. Sulphuric acid colours it to a dirty green. On analysis it was found to contain per cent. carbon, 55.76; hydrogen, 7.35; oxygen, 36.89. It is therefore free from nitrogen, and with dilute sulphuric acid it conducts itself as a glycoside.

Physiologically, it is exceedingly active. The watery infusion used therapeutically depends alone upon the digitalein extracted by the water. Whilst one milligramme of crystallised digitalin produces in from twenty to twenty-five minutes the characteristic stand-still of the heart in systole, the same result is produced with the equal quantity of digitalein from twelve to twenty minutes (in the frog).

The 'substance crystallisée inerte' of Nativelle has the following elementary composition: per cent. carbon, 53.26; hydrogen, 9; oxygen, 37.74. It occurs in white crystalline needles, is completely inodorous and tasteless, is soluble in hot alcohol, insoluble in water and cold alcohol.

BOEHM AND KNIE ON THE PHYSIOLOGICAL ACTION OF HYDROCYANIC ACID, AND THE PRETENDED ANTAGONISM OF HYDROCYANIC ACID AND ATROPIN.—Preyer affirmed that atropin was a certain antidote to hydrocyanic acid (*Die Blausäure physiologische übersucht*, Bonn, 1868-70). Professor R. Boehm and A. Knie (*Archiv für Experimentelle Pathologie und Pharmacologie*, Band ii.), from their experiments show that Preyer's affirmation is incorrect. They experimented for the most part on cats, which were often narcotised with chloral, which they recommend for this purpose. In all experiments tracheotomy was performed. Preyer employed almost exclusively rabbits. The hydrocyanic acid employed was the official, containing two per cent. It was always injected into the jugular vein. Preyer applied the drug to wounds, or to the mucous membrane, or injected it into the subcutaneous tissue, or let the animal respire it. The drug is most active when injected direct into the veins, and next to this comes inhalation.

The authors then criticise Preyer's experiments, and from their own investigations arrive at the following results.

1. Hydrocyanic acid acts on the central nervous system, the functions of which are abolished by large

doses after stimulation, *i.e.*, increase, of short duration. 2. The disturbances of respiration and circulation arise from analogous changes in the activity of their centres in the medulla oblongata. 3. The vagus does not play a part either by the action of hydrocyanic acid on the respiration, or by that on the heart. 4. Atropin is no antidote for hydrocyanic acid; the only rational method for the treatment of poisoning by this consists in the application of artificial respiration. WM. STIRLING, D.Sc., M.B., Leipsig.

MURIE ON THE HOMOLOGIES OF THE MUSCULUS STERNALIS BRUTORUM.—In the course of a paper 'On the Habits, Structure, and Relation of the Three-banded Armadillo' (*Tolyteutes conurus*) (*Transactions of the Linnean Society*, vol. xxx. p. 106) Dr. Murie discusses the much-vexed question of the homologie of the 'musculus sternalis brutorum'—a structure not unfrequently found in the human subject.

By some authors this muscle has been considered to represent a scantily developed layer of the panniculus carnosus; by others, an upward continuation of the rectus abdominis; by others, a downward prolongation of the sterno-mastoid; by others, as allied to the supra- or sterno-costalis; and, lastly, by the Dutch anatomist, Halbertsma, as a muscle *sui generis*.

[From the dissection of a Cape ant-eater (see *Transactions of the Linnean Society*, vol. xxvi. p. 568, pl. 45, fig. 1), in which the muscle in question coexisted with both a well-marked upward prolongation of the rectus abdominis and with a downward continuation of the sterno-mastoid, the reporter was led to conclude, with Professor Turner—'On the Musculus Sternalis' (*Journal of Anatomy and Physiology*, vol. i.)—that it is a true representation of the panniculus.—*Rep.*]

'From a study of the data,' says Dr. Murie, 'I am inclined to hold a middle view.' In the human subject its special name may be retained because of its variable nature and the possible junction of two different muscles and layers. It has evidently nothing to do with the supracostales, which lie at a deeper plane and whose fibres run nearly at a right angle to the overlying muscle. It can have no relation with the rectus, for this muscle, when produced upwards, may be as far as the first rib, runs beneath the supracostal. Its occasional connection with the pectoralis major and obliquus externus have been regarded by none, and rightly, as evidence of a relationship with either of these two structures. 'It may be admitted as unique in man, forasmuch as it frequently conjoins the sterno-mastoid and external oblique, &c.; but this by no means implies absence of its representative elements in animals. On the contrary, by its very irregularity is its composition best evinced.' When alone developed posteriorly it may be regarded as the true homologue of the panniculus, as Hallet, Turner, and the reporter have held; but its anterior end in relation to the sterno-mastoid has similarity to the rearward prolongation of that muscle existing in the three-banded armadillo, and so lends support to the views of Henle and Theile. The alleged objection of its lying on a plane beneath the platysma myoides rather strengthens the view as to its tegumentary character, for in the manatee 'an almost distinct sheet of the general robe of the panniculus starts from over the sternum, passes forwards beneath the transverse platysmal fibres *en route* to the malar arch.' If it can be shown hereafter, that as muscle

or tendinous prolongation, it goes superficially to, and does not become thoroughly fused with, the manubrial extremity of the sterno-mastoid, 'then, undoubtedly, the musculus sternalis is none other than a remnant of the lower mammalian cutaneous sheet.'

J. C. GALTON.

MORISON ON BONE-ABSORPTION BY MEANS OF GIANT-CELLS.—Mr. Alexander Morison (*Edinburgh Medical Journal* for October, 1873), taking up the researches of Kölliker on absorption of bone by means of giant-cells (see LONDON MEDICAL RECORD, 1873), finds, on examination of sections through the jaw prior to the formation of the tooth-sac, that many giant-cells contain clear round or oval holes of various sizes. The larger and more distinctly defined ones, in the centre of which a débris resembling fatty particles is sometimes to be detected, appear to be originated by a disintegration of minute portions of the protoplasm of the giant-cell. From this the author takes it as possible that the giant-cells, after having ceased to exercise their destructive, *i.e.* absorbing function, become disintegrated. Morison takes it also as probable that sequestra are separated from living bone by means of giant-cells, for, on examining a fresh sequestrum from a case of necrosis of the tibia, there were found Howship's lacunæ covering all aspects of the sequestrum, and the blood and pus around the preparation contained multinuclear giant-cells floating about.

As regards the origin of giant-cells, Morison agrees with Kölliker and others that many of them are in genetical connection with the osteoblasts, but that others probably develop from embryonic connective tissue; for there occur bone-spaces with here and there a giant-cell entirely destitute of osteoblasts, but containing the nuclei of embryonic connective tissue. These nuclei, generally scattered, are here and there closely aggregated and show an internuclear opacity, which, however, has not the distinctly granular appearance of the opaque cell-substance of a fully developed giant-cell; but this appearance is in variable degree, even in fully formed cells. It is possible that the aggregation of nuclei may be the first stage in the formation of a giant-cell; one has only to imagine that these nuclei prepare a cell-material each around itself, which, coalescing with that round its neighbours, produces the multinuclear giant-cell. E. KLEIN, M.D.

PATHOLOGY.

HANOT ON APHASIA IN GENERAL PARALYSIS. In the following abstract we have endeavoured to state the principal points of a paper by M. Victor Hanot (*Gazette Médicale de Paris*), upon the pathological history of aphasia, occurring during the course of general paralysis, and upon the indications of the thermometer in apoplectic seizures.

Aphasia, the author observes, is only exceptionally mentioned by authors as a symptom in general paralysis—*i.e.*, aphasia as distinguished from that hesitation in speech which may be regarded as an infallible indication of a diffused interstitial encephalitis (general paralysis). According to Baillarger, this paralytic hesitation results from spasmodic muscular action. Requin attributes it to feebleness

of muscular action. Slowness of utterance may exist for some time, especially at the commencement, before tremor of either the tongue or lips is apparent. At that time it is doubtless attributable to a morbid state of the cortical substance, involving disorder of memory and ideation. Subsequently, however, this is brought into association with muscular tremor of the tongue and lips, which M. Hanot subsequently refers to sclerosis of the white substance. Is it certain, the author asks, that these tremulous movements of the muscles concerned in phonation are of a convulsive nature? Doubtless, he adds, the tremor of the tongue and lips and the persistence, for a variable period, of muscular power in the limbs already affected with trembling, would seem to indicate a spasmodic character; but, as is well known, this apparent integrity of the muscles is followed by actual paralysis. Charcot is of opinion that the tremor in vocalisation depends upon muscular feebleness, and partakes of the paretic rather than the spasmodic or convulsive character.

This trembling of the muscles is, beyond doubt, solely attributable to changes in the cortical layer of the convolutions; but it should also be borne in mind that, by extension of morbid processes, sclerosis of the medulla oblongata, and even of the spinal cord, is ultimately superadded to the lesions of the convolutions.

Sclérose en plaques has been shown by Charcot and other pathologists to be one of the morbid conditions in paralysis agitans. Large modifications of this form of aphasia are met with, varying from simple hesitation and the misplacement of letters, volubility alternating with slowness of utterance, up to unintelligible jabber and the impossibility to articulate the simplest words, that is characteristic of the latest stages of the malady. It is difficult, sometimes, to distinguish between the hesitation of speech of general paralysis and of sclerosis (paralysis agitans). In the former, however, there is generally a complete unconsciousness of the defect.

A case related by M. Hanot showed that, although exceptionally, genuine aphasia may occur in general paralysis. It may, however, be asked why this coincidence should not be more frequently met with, since the frontal convolutions are more or less involved in diffused interstitial encephalitis. This is doubtless a question of degree, while it is probable, as observed by Parchappe, that aphasia does not occur from lesion of the grey matter only, but from implication also of the white fibres. The maximum degree of alteration was observed, in the present instance, in the left frontal lobes, although those on the right side were also atrophied.

Sections of the convolutions showed the degree to which the change had advanced in both the white and grey matter of the frontal lobes, and exhibited thickening to the extent of three or four times its normal volume over the atrophied convolutions. The want of symmetry is not indicated by any clinical signs, but on microscopical examination will be found to depend upon the greater or less extent of sclerotic changes, which may be so slight as to be scarcely detectible. Doubtless these changes in the connective tissue influence the nutrition of the nerve-cells, the trophic influence of which in the spinal cord has been dwelt upon in the writings of Brown-Séquard, Charcot, Vulpian, and others.

With reference to the diagnostic value of the thermometrical indications in these cases, M. Hanot states that, in his own and M. Westphal's observa-

tions, they found that in the sudden congestive seizures of general paralysis the temperature rises immediately after the attack and continues to rise until death. On the other hand, the author adds, MM. Charcot and Lépine have shown that in comatose attacks from cerebral or meningeal hæmorrhage, the temperature falls, or remains stationary after the attack, to rise before death takes place. M. Bourneville has observed the former state of things in uræmic seizures. W. B. KESTEVEN.

LUBIMOFF ON THE PATHOLOGY OF GENERAL PARALYSIS OF THE INSANE, WITH SPECIAL REFERENCE TO A COLLOID DEGENERATION OF THE VESSELS OF THE BRAIN.—Dr. Alexis Lubimoff, of Moscow (*Archiv für Psychiatrie*, 1874), agrees with most observers in thinking that there is a chronic interstitial inflammatory process, and an increased development of spindle-shaped connective tissue cells. These are shown best in preparations after Lockhart Clarke's method, and especially to advantage in slowly made ones. Taking his materials chiefly from the frontal convolutions, he has studied the blood-vessels, nerve-elements, and the development of connective-tissue. As to the first, he finds that there is no new formation, as some have asserted; but in no disease connected with psychiatry is there so great an accumulation of granules round the vessel. Meyer thinks these young elements are a result of proliferation, but Lubimoff that the walls of the vessel have undergone a process of decomposition; at times these granules look like extravasated blood, and certainly red blood-corpuscles and heaps of pigment are often found among them. The vessel walls are often found thickened by a homogeneous shining mass, which he calls 'colloid' or 'waxy' degeneration, in no way related to amyloid.

Rokitansky in his treatise describes colloid degeneration of the nerve-elements, but says nothing about the walls of the vessels. Billroth describes a yellow gelatinous decomposition of vessels in a cerebellum, but the patient had not progressive paralysis. Schüle and Arndt have met with appearances similar to Lubimoff's in the transition layers where the grey substance passes into the white. The vessels affected are chiefly met with in the deep grey layers, and vessels have been traced from the pia mater through the grey matter, and into the white, which only showed this colloid alteration in the deep grey layers. It consists of a homogeneous transparent shining thickening of the walls without striation, either regularly disposed, or in the larger vessels granular. These granules are of different sizes and placed irregularly, and cannot be mistaken for the proper nuclei of the walls. By transmitted light the vessel-wall is brilliant, but dark by reflected light. Chemically examined, it resists many tests. The granular form looks as if composed of lime, but it resists all the tests for that and for fat, amyloid, &c. Alkalies only cause a swelling of the vessel wall. Carmine is not imbibed, and the xantho-proteine reaction gives a faint yellow. Where this colloid degeneration has attacked the vessels, no proliferation of new elements is seen, as is so frequent in progressive paralysis, nor are there pigment-masses and spindle-shaped cells, though these can be seen in other sections where the colloid vessels do not show. The changes in the nerve-cells consist of diminution of size, and in substitution of granules for the proper nuclei; at another time the cell-wall seems to have decayed, and the nuclei are surrounded with granular matter.

The spindle-shaped cells of the connective tissue vary in shape in different parts of the brain, and much care is required in speaking of any change in them. They are to be seen principally with their long delicate processes (the Deiters' cells of Dr. F. Boll), and in Lubimoff's experience seem always more or less pressed out. He describes what he calls 'Nester'—groups of these cells surrounding the vessels, not closely hugging them, but placed at a little distance and apparently holding communication with the vessel by their long hairy processes. One explanation of the occurrence of psychic lesions alternating with lucid intervals, appears to rest on the temporary swelling of these spindle-cells as a result of hyperæmia. Most of the pathological changes in general paresis are to be found in the fifth grey layer and in the part near to it where the grey substance passes into the white, whilst the special lesions of the ninth and seventh nerves must be sought in the neighbourhood of the fourth ventricle, and in the aqueduct of Sylvius.

The author concludes by terming the spindle-cells of the fifth layer which have thin and tender processes, the 'mediums of association,' whilst those of the pyramids which are thicker and coarser he terms 'mediums of projection'; and he draws up a theory as to the functions of these cells in connection with the phenomenon so often seen in brain-disease, of memory of things long since passed away but forgetfulness of quite recent events.

MEDICINE.

EMMINGHAUS ON EPILEPTIC SWEAT.—Dr. H. Emminghaus (*Archiv für Psychiatrie*, 1874), recently met with two cases which confirm some of Griesinger's remarks on epilepsy. In both of them epileptic conditions were present, and in both paroxysms of sweating, which in the woman were accompanied by feelings of giddiness, though this combination did not invariably occur in the man. In the woman there had been attacks in childhood, sweating with fainting at the climacteric period, and she had the peculiar epileptic expression, contraction at the corners of the mouth, form of skull, etc. In the other case there had been no true fits, only indefinite signs of them, but there was strong hereditary predisposition, and he indulged in spirituous liquors. Griesinger's remark was that 'sudden outbreaks of sweat often are connected with epileptic nusus,' and that all sorts of symptoms such as cold in the feet, sudden blushing, gastralgia, greediness, should be borne in mind as connected with epilepsy, for then alone they get their true interpretation. The woman's case showed a fact noted by Griesinger, that often an epilepsy which appears in childhood disappears afterwards, and then returns after periods of ten years; she had been free from the fits since puberty, and the sweating began when she was fifty. In his book on diseases of children, Emminghaus relates the case of a boy affected with mitral disease, and whose sister had *petit mal*, in whom, besides constitutional weakness, there were muscular spasms and loss of consciousness when voluntary muscular efforts, such as running, were made. Many persons ascribe the sweating of epileptics to the excessive muscular action; but this is not always the case, for in the instances above noted the eruption of sweat was directly

connected with the vaso-motor affection of the complaint.

T. C. SHAW, M.D.

BARTELS ON PERIPLEURITIS.—Bartels (of Kiel) in the *Deutsche Archiv für Klinische Medicin*, 1874, narrates three cases of peripleuritis. By peripleuritis is understood a suppurative inflammation in the costo-pleural cellular tissue, occurring independently of traumatic causes or of pleurisy. This disease is rare. The only other reported cases are two by Billroth, two by Wunderlich, and one by Suadicani—making a total of eight cases. Respecting its etiology, Bartels says nothing is known. The abscess appears to have little tendency to open internally into the pleura. It sometimes by extension causes pericarditis. Nephritis is a common complication.

In speaking of diagnosis, Bartels says the important point is to distinguish this condition from empyema. The affected side of the thorax is sometimes as much bulged and as motionless in peripleuritis as in pleural effusion, but in the former disease the bulging has a much greater tendency to become especially prominent in one or two intercostal spaces. The form of dulness differs also in the two diseases. In peripleuritis the inferior portions of the thorax are usually resonant, and the lower border of the lung descends during deep inspiration. Another important feature of peripleuritis is the complete absence of any displacement of neighbouring organs. When fluctuation is discoverable in an intercostal space, the abscess usually becomes less tense during inspiration and more so during expiration. The prognosis is grave. Of the eight reported cases four died, in two recovery was complete, and in the remaining two fistulous openings and deformity were left. The important point in the treatment is evacuate the pus as early and as completely as possible.

SYPHILOGRAPHY.

BRUBERGER ON SYPHILITIC MENINGITIS AND SYPHILITIC CEREBRAL DISEASE.—In making this valuable contribution to the pathology of syphilis of the nervous tissues, Dr. Bruberger (*Virchow's Archiv*, May 6, 1874) narrates with extreme minuteness the clinical history and *post mortem* examination of a patient who contracted syphilis in 1871, had destructive ulceration of the soft palate two years later, and sudden complete motor paralysis of the arms and legs occurring while under excitement partly alcoholic, partly of another kind. The paralysis was so complete that the patient was unable to move a finger or toe, or make the slightest effort to change his position in bed. Meanwhile, the cutaneous sensibility of the body and limbs was ascertained by many careful experiments to be only very slightly diminished, and the susceptibility of the muscles to electrical stimulus was as keen as in health. The muscles of the face and of respiration were not paralysed, nor was control of the sphincters wholly lost. Consciousness was lost only for a few moments, and, having returned, remained unimpaired to the last. The intellect was also intact. Iodide of potassium, in large doses, was administered for four weeks, and then changed for mercurial inunction. Six weeks after admission the patient regained the power of slowly clenching the fist and opening the hand again, but no other improvement ensued. After lingering nearly four months, he sank exhausted by bed-sores and vesical

irritation. In making the diagnosis, no hypothesis explained all the symptoms. The bilateral symmetry of the motor palsy and the unimpaired sensorium suggested the cord to be the part attacked. The suddenness of onset indicated extensive hæmorrhage or plugging of a large artery, were it not that in syphilis paralysis does occur suddenly without either of these conditions being found after death. Again, a thrombosis or hæmorrhage would have almost certainly produced some hemiplegia. Local softening or the presence of a gumma in the medullary tissue was, like hæmorrhage, precluded by the undiminished intellectual power. Lastly, disease of the meninges at the base, a frequent form of cranial syphilis, was rendered improbable by the absence of peripheral irritation of all kinds; neither convulsions nor slowness of pulse, nor sinking in of the abdomen, &c. were present. But the *post mortem* examination revealed most unexpected conditions, the principal being inflammatory thickening of the dura and pia mater in the cervical portion of the spinal cord and base of the brain, producing a leathery sheath which had formed numerous attachments to the medulla and to the bony surfaces. There were also hæmorrhages into the spinal cord, with atrophy of the grey substance and considerable widening of the central canal. In the skull, inflammation had spread widely through the meninges over the basilar bone, and had changed the pia mater at the base of the brain into a thick grey glue-like mass. Another striking alteration was a peculiar change in the vessels of the skull, causing thickening of their walls and a nodular condition of their calibre; the arteries throughout the rest of the body being free from perceptible change. The remaining phenomena had nothing specially syphilitic. The author then recapitulates the points of interest in the case, and has collected the published records of syphilitic disease in arteries which consist mainly of the observations of Hughlings Jackson, Moxon, and Clifford Allbutt, and of one or two others. These observations show that ordinary atheroma, if at all a syphilitic product, is not the usual arterial affection, which consists of irregular thickening of the coats, especially of the middle tunic of the vessel, producing nodular projections with narrowing and some loss of elasticity of the vessel, but no fatty or calcareous degeneration of its walls: further, that this inflammatory change of the arteries is very local, attacking the vessels of one or two regions, and not spreading through the arterial system generally. After remarking that the extensive disease of the meninges caused no convulsive affection of any kind, again a peculiarity of syphilitic meningeal disease, the author notes, without offering an explanation, the curious fact that sensation was intact throughout the body, and yet the grey matter of the cord was far advanced in atrophy, while the white fibres were so tightly strangled at one point of the medulla as to produce almost total loss of voluntary muscular power.

BERKELEY HILL.

PUBLIC HEALTH.

THE SANITARY LAWS AMENDMENTS BILL.

The Parliamentary Bills Committee of the British Medical Association have submitted this document to a few of the leading Medical Officers of Health. From their report we learn that replies have been

received from the following medical officers of health: Dr. Bond, Gloucester; Dr. Child, Oxford; Dr. Fox, Chelmsford; Mr. Haviland, Northampton; Dr. Wilson, Leamington; Dr. Syson, Huntingdon.

Dr. Bond has not attempted to criticise or amend the proposed Bill, believing that it has been drawn up 'to meet the administrative exigencies of the office'; but has confined himself to 'suggestions for the consideration of the Committee as addenda to Mr. Sclater-Booth's Bill.' These 'addenda' comprise eighteen clauses as to 'sewers and drains,' 'removal of nuisances,' and extended definition of the word 'nuisance'; 'prevention of the spread of infectious diseases,' by providing hospitals and inflicting penalties for exposure; enlarged interpretation of 'person in charge'; also rendering it imperative on medical practitioners to forward as early as possible notice of infectious cases, and payment for such notice; also as to 'water-supply,' and 'provision of privies and water-closets.' Under this last head Dr. Bond proposes in certain cases to empower an owner of property not having any land on which to erect a privy or privies, to acquire such land from his neighbour, provided no nuisance or annoyance, public or private, is created thereby.

Dr. Child is of opinion that, 'if passed as it stands, much of the Bill would be a dead letter in country districts,' owing to its 'permitting people to do things which they have not the slightest intention of doing.' Dr. Child suggests that sections 50 and 55 (?) should be rendered compulsory, and considers sections 11, 50, and 41 to 49, as the most important in the Bill, particularly 47 and 48, as giving power to a rural sanitary authority to make bye-laws. But he thinks these clauses are by no means clearly expressed, and will be perfectly useless, unless rendered compulsory. As to omissions in the Bill, Dr. Child complains (1) that it contains no provision for rendering the appointment of a Sanitary Committee compulsory; and that, without the appointment of such a Committee, it is impossible for any ordinary Board of Guardians to do any serious sanitary work. Dr. Child therefore suggests that the appointment of a Sanitary Committee should be made compulsory, and that it should be put upon the same footing as the Assessment Committee. Another omission noticed is, that the Bill contains no clause conferring any legal status on the Central Committee for a compound district. Dr. Child also suggests that the power of compelling combination of two or more port sanitary authorities should be extended (under Section 14) to all sanitary authorities. In Section 41, Dr. Child would add, 'or inspectors of nuisances' after the word 'surveyor.' Attention is also drawn to the omission of all further provision for the prevention of the spread of infectious diseases, and 'of all systematic attempt to arrange, simplify, and consolidate the forty Acts or so which now constitute what is understood (?) by "sanitary law."' However, Dr. Child would take the Bill for what it is, as he thinks it professedly leaves more weighty and disputed matters to be dealt with more at leisure next session. The urgent need for amended legislation, Dr. Child thinks, is very great; and that, until medical officers are assisted by such legislation, their work is paralysed.

Dr. Fox thinks the designation of the Bill in the *British Medical Journal* as 'in the main an office Bill' is the correct one. He is of opinion that five clauses only will be of service in his districts—viz., 11, 20, 56 and 50; and suggests that in clause 50, after the words 'if it shall be represented to any

'sanitary authority,' the words 'by the medical officer of health' shall be inserted, as an inspector of nuisances is not competent to give an opinion as to the quality of water. Adopting the 'omissions' alluded to in the *British Medical Journal*, Dr. Fox calls attention to others, viz.: 1. The omission of any provision as to returns of mortality and payment for the same; 2. Omission of any clause empowering a medical officer of health to inspect, for the purpose of making his returns or reports, the books of a registrar of births and deaths; 3. The omission of provisions for checking the spread of infectious diseases; 4. Overcrowding.

Dr. Wilson, of Leamington, is of opinion that 'no urgent necessity for further sanitary legislation this session exists; but, as the bill is a Government measure, he would suggest that Clause 5 should also make provision for giving a legal status to the committee of delegates; that Clause 21 should also apply to every rural sanitary authority invested with urban power; that to Clause 33 should be added words giving any sanitary authority compulsory powers to acquire land for dealing with sewage; that Clause 50 should be altered so as to enable any sanitary authority to close any well, &c., immediately on having reason to believe that it was polluted; also that any sanitary authority should be enabled to call upon owners to provide proper water-supply. Dr. Wilson also makes several suggestions, in the main similar to those made by Drs. Bond, Child, and Wilson as to infectious diseases; and would like to see every rural sanitary authority endowed with powers to make bye-laws as to dwellings, ashpits, privies, and cesspools, common lodging-houses, and slaughter-houses. He also suggests that the Local Government Board should be empowered to enforce combination; and that such combinations should not be dissolved without their consent.

Dr. Syson suggests that Mr. Sclater-Booth's bill should be accepted as far as it goes, but that attempts should be made so verbally to alter Clause 45 as to make it clear that rural sanitary authorities can and may make bye-laws on all matters on which an urban authority may make bye-laws; and that, by order of the Local Government Board, any sanitary authority *shall* make bye-laws on one or all these matters; that Section 50 of the Act should be amended so as to enable any sanitary authority to order the closure of any well, &c., on the certificate of any public analyst or their medical officer of health; power being given to rescind such order on being satisfied that the water, etc., has become or been rendered fit for drinking purposes; that, looking at the Bill as an 'office Bill,' it is highly important to specify what drains, sewers, etc., do, and what do not, belong to a rural sanitary authority (the same as to urban authority); that all drains, privies, water-closets, cesspools, and ashpits, shall be under the control and survey of the sanitary authority, and shall be altered, repaired, or reconstructed from time to time as they may think fit. With regard to the seizure of diseased meat, Dr. Syson suggests that any policeman should be empowered to seize meat at any time, just as inspectors of nuisances are now empowered to do; and that, 'dealt with by a magistrate,' in 25 and 26 Vict., c. 117, s. 2, should be interpreted so as to facilitate and unify proceedings under that Act. Also that power should be given to all sanitary authorities to close any house, or part of a house, presented to them by their medical officer of health as unfit for human habitation, power being

reserved to revoke such order on proof of fitness for habitation.

The Parliamentary Bills Committee have recommended that a deputation should wait on the Private Secretary to the President of the Local Government Board, and urge the great desirability of the following amendments and addenda to the Public Health Amendment Act now before Parliament.

The Committee have divided their recommendations into two parts. Firstly, amendments and addenda, without which they believe Mr. Sclater-Booth's Act will be of little or no service, even as a temporary measure; secondly, points entirely omitted in any existing sanitary Act, but as to the necessity of which almost all medical officers of health and sanitarians are strongly convinced.

The Committee found, after extensive inquiry, that Clauses 10 and 11 were everywhere hailed with great satisfaction as removing serious existing obstacles in the way of sanitary work.

An unanimous expression of opinion was also elicited that the principle laid down by Clause 14, should be carried still further; the Committee therefore, recommend that the following Clause, or one similar in extent or purpose, be added to the Bill.

Sanitary Authorities may be combined.—The Local Government Board may combine the sanitary authorities of several districts, urban as well as rural, or both, and assign to such authority a title, and otherwise proceed, as in the case of an ordinary combination of sanitary authorities, rural and urban, or both. And such combination shall be an united district to which all the provisions of the Sanitary Acts which relate to sanitary authority shall apply, except a necessity for any previous application to the Local Government Board and previous inquiry.

In Clause 21, it seems most desirable that the words 'or rural' should follow the word 'urban,' or else the word 'urban' should be omitted. The great urgency and necessity for the addition of these words having been most strongly urged from all quarters. The Clause should, therefore, read, 'Every urban or rural sanitary authority (or Every sanitary authority) shall, where the Local Government Board direct, make due provision for the purpose—cleansing of streets, the removal of house refuse from premises, and the cleansing of earth-closets, privies, ashpits, and cesspools within its district.'

It appears desirable also to add 'and employing and removing the contents' after the word 'cleansing.'

As the adoption of the foregoing amendment might entail considerable responsibility on a sanitary authority, the following Clause is recommended as a necessary sequel. 'All privies, drains, ashpits, and cesspools shall be under the control and survey of the sanitary authority, and shall be altered, repaired, or reconstructed from time to time as the sanitary authority may think fit.'

It also seems desirable to add to such a Clause—'And no new privy, cesspool, ash-pit, water-closet, or earth-closet shall be erected without the plans for the same having been submitted to and approved by the sanitary authority.'

The Committee have been informed that several Local Acts contain Clauses similar to this suggested one, so no new principle or apparent infringement of private rights would be involved by its adoption.

The Committee think it would be desirable to state in Clause 40 that this Clause in no way affects the powers of a sanitary authority to conduct proceedings and issue notices through and by any officer

duly authorised by resolution, special or general, under 29 and 30 Vict., c. 90, sec. 48.

To Section 31, should be added, for the sake of the convenience of persons living in rural districts 'at the office of or to Inspector of Nuisances.'

Also, as the appointment of 'surveyor' is neither compulsory nor universal, a Clause to the following effect is recommended. 'Where no "surveyor" has been appointed by a sanitary authority, any notices or orders which a surveyor is appointed to receive or serve under any Sanitary Act shall, with the consent or by orders of the Local Government Board, be served or received by the Inspector of Nuisances.' This appears to be a most important addition, as many notices under the Sanitary Acts are to issue from and be signed from the 'surveyor,' who also has powers of immediate action in cases of emergency conferred upon him (*vide* page 29 Official Digest. Rural Sanitary Authorities).

As Clauses 47 and 48 are rather vague, it is suggested that the following Clause be added to the Bill. 'After the passing of this Act, any rural sanitary authority may, and by order of the Local Government Board shall, be endowed with and exercise any of the powers, duties, discretions or authorities vested in or exercised by any urban sanitary authority under this or any other Sanitary Act.' By Sanitary Acts in this Act is meant 'the Local Government Acts,' 'the Sewage Utilisation Acts,' the 'Nuisance Removal Acts,' 'Common Lodging-houses Acts,' 'Diseases Prevention Acts,' 'Bakehouse Regulation Act,' the 'Artisans' and Labourers' Dwellings Act,' 'Baths and Washhouses Act,' the 'Labouring Classes Lodging-house Acts,' and the 'Public Health Act, 1872.'

Clause 50 has been generally welcomed; but, at the same time, from the strictures passed upon its wording, the Committee recommend the substitution of the following.

'If it shall be represented in writing to any sanitary authority by the medical officer of health or the public analyst that, within their district, the water in any well, spring, pump, tank, or pond used for drinking purposes is so polluted as to be unfit for drinking purposes, such authority may, by their order conspicuously affixed at, to, or near such well, spring, pump, tank, or pond, direct the same to be closed, or make or take all necessary steps to close the same; provided always that they may at any time revoke such order, on proof being afforded that the water has become or been rendered fit for drinking purposes.'

'Any person aggrieved by such order may appeal to the justices having jurisdiction within the district, who, if they think fit, may order an analysis to be made, and may, if such analysis be favourable, revoke the order made by the sanitary authority.'

'In reporting on the water in any well, pump, spring, or tank, the medical officer of health or public analyst shall state whether, in his opinion, there is a probability of such water recovering its purity within reasonable time.'

The Committee would also suggest that Clause 55 be still further extended, so as to enable a police officer as well as a medical officer of health or inspector of nuisances (26 & 27 Vict. c. 117, sec. 2), at all reasonable times, to examine and, if necessary, seize any unwholesome food, etc.

Also, in order to be dealt with by a magistrate, it shall suffice, if one be not within one mile from the place where the meat was seized, to retain, or if necessary, destroy the meat, &c., and summon the

person in whose charge or possession the meat, &c., was found to the next petty sessions. But in no case must any meat, &c., be destroyed until it has been inspected and examined by the medical officer of health or his legally qualified deputy.

So far, the Committee have touched only upon points raised in or by Mr. Sclater-Booth's Act. They would, however, most emphatically urge the urgent necessity for immediate provision being made for the payment of registrars for mortality returns.

This has been suggested (and authorised) to sanitary authorities by a circular letter from the Local Government Board. As the Local Government Board possesses no compulsory powers in this matter, their recommendation has in numberless districts been unattended to. The circular letter above referred to recommended that returns should be furnished and payment made according to the scale laid down in Sir C. Adderley's Bill.

The committee urge the Local Government Board's suggestion on the Government, and would also suggest the following addition as an appendage to it.

'And it shall be lawful for any officer of health, at all reasonable times after one week's notice in writing, to inspect the books of the registrars or sub-registrars of births and deaths, and to make notes and extracts from them for the purpose of making or compiling his reports, returns, or statistics.'

At present, registrars may and do refuse to allow their books to be inspected, although, without such inspection, no officer of health can make the returns required of him by Act of Parliament and by the Local Government Board. No provision is made for preventing the further spread of infectious diseases; no provision of fever hospitals is made compulsory on sanitary authorities; nor is any provision made for early information of new cases of infectious sickness from medical men.

'Overcrowding' is entirely overlooked, and the Committee would suggest that, by the repeal in this Act of 18 & 19 Vict. c. 121, s. 29, of the words 'consisting of more than one family,' would leave the medical officer of health all-powerful under the definition of nuisances, 18 & 19 Vict. c. 121, s. 8; 29 & 30 Vict. c. 90, s. 19.

If it be the opinion of the law officers of the Crown that the definition of 'any house or part of a house so overcrowded as to be dangerous or prejudicial to the health of the inmates' is irrespective of the limitation as to 'more than one family' in 18 & 19 Vict. c. 121, s. 29, a declaration of this opinion will, of course, be equivalent to a new and amended clause.

On the above and many other matters, the suggestions of Dr. Bond, medical officer of health for Gloucester, are very valuable, and they are handed in as likely to diminish the labours of the Local Government Department in framing amended sanitary legislation. The Parliamentary Bills Committee of the British Medical Association have, however, through their deputation, endeavoured as far as possible to be very brief, and for the present only attempt to render existing legislation officially workable, and to render the duties required of medical officers of health by Acts of Parliament, the orders of the Local Government Board and public opinion fairly practicable. As a last word, the Committee was convinced of the desirability of the introduction of a clause rendering every Act permissible by any sanitary authority compulsory by order of the Local Government Board.

Also that, owing to the working of some of the

clauses in Mr. Sclater-Booth's Bill, the final clause should state, except where expressly repealed, all powers conferred were in addition to, and not in lieu of, any already conferred by existing Acts.

NEW INVENTIONS.

A NEW VAGINAL 'PORTE-TOPIQUE.'

At the sitting of the French Academy, held on May 19, M. Delisle laid before the meeting a new instrument, which he calls 'porte-topique vaginal.' This instrument is manufactured by M. Galante, of Paris, from vulcanised India-rubber, in different sizes. It gives the patient the power of applying with as much ease as she can administer to herself a liquid injection to the vagina and the neck of the uterus, any medicinal substances the medical man may desire to apply locally, such as plugs of wadding or lint, sponges, medicated bags filled with powder,

or poultices; ointments, unguents, and powders of all kinds. The 'porte-topique' thus enables the patient to wear, according to the orders of her medical attendant, all kinds of vaginal topical applications, whether solid, soft, or pulverulent, and even medicated liquids, either on wadding, lint, amadou, or sponge, or held in suspension by a powder or poultice. This topical application made by the patient herself has the advantage of giving her the power of renewing the dressings every day, and even, if necessary, several times a day; whilst now as a rule they are only attended to once or twice a week. The medical attendant is also able to substitute in his prescriptions a powder, ointment, or the application of a plug or bag, for liquid injections; consequently changing the transient and rapid action of a liquid by the sustained action of a permanent topical application.

Description of the Instrument.—Fig. 1, *Stroke* indicating the line according to which the 'porte-topique' is divided throughout its whole length into

two valves. *VV*, the sheath; furnished at its neck with a groove, in which is placed an India-rubber ring, *a*, which, from its elasticity, keeps the valves together. *e*, Stopper closing the opening of the sheath, *p*, and into which the stem of the piston, *t*, slips.

Fig. 2. Position of the hands whilst using the

instrument. The left hand, *g*, holds the instrument whilst the right hand, *d*, works the piston.

Fig. 3. Position of the instrument whilst it is being charged with the medicinal substance.

Fig. 4. Arrangement of the instrument to attach the string, *c*, of a plug, bag, or sponge, *s*, to the opening in the piston.

REVIEW.

Arrangement of Houses. A Paper read before the Belfast Architectural Association, January, 1874. By HENRY MAC CORMAC, M.D.

The common saying that the beautiful is not the useful is here virtually derided, for the pamphlet before us combines the æsthetical and the practical in a highly satisfactory manner.

Under each of the heads of air, water, sewage, light, warmth, convenience, and grace—the satisfactory treatment of which may be considered as the seven standard tests of the seven architectural orders—a few sensible remarks are grouped together. The paper is merely suggestive in character, yet contains hints which no one can afford to neglect if they desire a well-arranged, sufficiently lighted, properly drained, and artistically treated residence. According to the writer, the architect is often as ignorant as his client as to what, for example, constitutes good ventilation; and upon this subject, and upon that of heating, he has something noteworthy to say. It is a pamphlet with which no architect can find fault, and if our pupils of the house-constructing professions were made to translate it into another language, and back again into English, without the aid of the original, they would have impressed upon their memories what would benefit them throughout all their after life. We want more of these papers from the pens of our competent medical men, for they are best able to gauge the shortcomings of the houses which they visit. The physician, the artist, and the engineer, will never be discoverable to perfection in one man, but the powers of criticism in each should fairly be found in the architect, if not as well in the master builder.

MISCELLANY.

THE Chair of Pathological Anatomy in Vienna has, it is reported, been offered to Professor Cohnheim, of Breslau.

PROPAGATION OF FEVER.—We take the following striking passage from a 'Report on the Sanitary Condition of the Rural District of Aston Union,' by Dr. Hickinbotham, Medical Officer of Health: 'Children are daily sent to school whose brothers or sisters are "down with fever." I have known often the body and bed-linen of a patient suffering from contagious disease sent to the public washerwoman without the slightest attempt at disinfection, and, on the other hand, I have known laundresses have, at the same time, a house full of scarlet fever, and of clothes to be sent home and worn by half the neighbourhood.'

OVERCROWDING.—Medical officers of health and inspectors under the Public Health Act have been much hampered by the belief that, so long as the inmates consisted of one family, there was no legal remedy. The opinion is, however, expressed in a communication from the Local Government Board to the Rural Sanitary Authority of Bedford, that proceedings can be taken under clause 1 of section 19 of the Sanitary Act, 1866, although the house complained of is occupied only by one family. If this prove to be so, it will be an instrument of great sanitary and moral power in the hands of the local authorities.

USE OF ANILINE FOR COLOURING SAUSAGES.—E. Reichardt (*Medico-Chirurgical Review*), points out in a paper that the manufacturer, in order to give colour to inferior soluble matters used for sausages, sometimes adds

aniline to represent the colour of the blood. Sausage-meat thus tinted is charged with a substance which, habitually consumed, would prove very injurious to the health of the consumer, and in addition it may admit arsenic into the system as an accidental impurity of the aniline. To detect the fraud the meat should be finely minced and then digested with a mixture of alcohol and ether. In this solution the aniline, if it be present, will be dissolved and will give a tinted solution. Blood-colouring matter, on the other hand, if it alone be present, will not yield any soluble colour-stuff to the solution.

CONTAGIOUS DISEASES ACT.—Under this head we read the following in the recently published annual report of the health of the navy. The continued beneficial influence of the operation of the Contagious Diseases Act on the force at the various home ports is now so fully recognised by medical officers, that they have almost ceased to make any direct allusion to it, accepting it simply as a well-established fact. Whenever it is referred to, it is mentioned in the highest possible terms, and the only regret expressed in connection with it is that the Act is not more extended in its application. A large proportion of the disease that exists in protected ports is readily traced to importation from unprotected districts; and if these could only be reached by legislation strictly carried out there appears to be little doubt that the more destructive forms of disease might be almost altogether stamped out. The staff surgeon of the *Indus* at Davenport remarks, 'The number of cases of syphilis, both primary and secondary, have been very few; and the Act for the protection and examination of these poor creatures still continues to flourish and work good works. Regardless of its enemies and opponents, it still protects us from an overwhelming number of cases of disease.' On the other hand, in alluding to an unprotected port, Hull, the staff surgeon of the *Audacious* remarks, 'The port of Hull is the origin and cause of nearly all the cases (of syphilis), the town being a filthy focus for foul prostitutes, and native and foreign seamen, reckless, dissipated, and degraded. . . . Had the great benefits conferred by the useful Contagious Diseases Act on the more fortunate towns been extended to this port, we should not have to chronicle the fifty-four cases of secondary constitutional disease, which testify to an equal number of ruined constitutions, with the moral depravity, and consequently numerous, but necessary, punishments which must invariably follow.'

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S.W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JULY 15, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

GOODELL ON DISEASES OF WOMEN.*

In this short practical treatise on the treatment of prevention of uterine affections the subject is divided into two parts, treatment and prevention. A considerable portion of the latter part is addressed to the lay community, as the author considers that many uterine complaints are due to the Moloch of Fashion.

Instruments.—For the successful and intelligent treatment of ordinary uterine affections, the writer believes the following articles to be absolutely essential. A short bivalve expanding speculum with blades only $3\frac{3}{4}$ inches long; as by stretching the uterine end of the vagina the cervix is brought down nearer to the field of vision, and if required within the reach of the index finger. Two glass (Fergusson's) specula, one $5\frac{3}{4}$ inches long with smaller aperture $1\frac{1}{4}$ inch in diameter; the other 5 inches long, with an orifice $\frac{7}{8}$ of an inch in diameter. Two applicators of aluminium wire with an adjustable handle; an uterine tenaculum-sound, repositor, dilator, volsella-forceps, speculum-forceps, and a gutta-percha uterine syringe, with a long and flexible nozzle. The use of these instruments will be indicated in speaking of the affections for which they are employed. Aluminium is recommended for the applicators, as being flexible and not acted upon by the various corrosive agents used in uterine therapeutics.

Local Treatment.—The following agents are required: pure liquid carbolic acid (Calvert, no. 4) or a saturated solution of the crystals; a solution of nitrate of silver (one drachm to the ounce of glycerine), a saturated solution of tincture of iodine; fuming nitric acid; and a solid stick of nitrate of silver. With the exception of the last, each caustic is applied by means of a film of cotton-wool wrapped evenly round the applicator for about two inches of its length. This probe thus covered is dipped in one of the liquids, and is always carried, through a speculum, up to 'the fundus of the uterus whenever the internal os permits its passage.' In the majority of cases, this can be done if the anterior lip of the cervix be hooked down, which steadies the womb and straightens it out. The reasons assigned for cauterising the whole of the mucous tract are as follows. 1. If the mucous coat be alone involved, the symptoms often fail in showing how far the disease has extended. 2. Through absence of submucous areolar tissue, inflammation of the membrane must sooner or later involve the parenchymatous structure, and this is to be avoided at all hazards. 3. The passage of the armed applicator through the internal os is accepted as evidence that the disease is not limited to the

cervix. 4. This method, although empirical, is an error on the safe side, judged by the results. Nor is the bolder plan more dangerous than the ordinary limited one. The writer states that out of a yearly average of this kind of over 1,500 hospital cases without his private patients, he has not heard of a death from this cause. In fact none but slight and manageable attacks of perimetritis have followed, and these very seldom. Even sponge-tents have been introduced in the out-patient department, and in only one instance, and that in a woman with fibroid tumour, did any mischief result; in hers the tents were introduced in her own home. And in this case the mischief is attributed more to the repeated intrauterine examination. The most successful gynaecologist he believes to be the pluckiest. Should any pelvic inflammation arise from uterine treatment, from 16 to 24 grains of quinine are given during the twenty-four hours, quarter-grain doses of morphia to relieve the pain, and with a rapid pulse 60 to 80 grains of bromide of potassium. The abdomen is painted with a strong solution of iodine. With the exception of fuming nitric acid, the liquid applications are made once a week, and frequently changed. To be sure that the cauterisation is complete, it is necessary to repeat the application two or three times until the uterus is irritated to contract on the probe. When the cervical canal is not very patulous, it is advisable to enlarge the canal with the dilator. Fuming nitric acid should not be used unless the cervix be very open. Immediately after its use the uterus should be syringed out several times with water, and a tampon of cotton-wool, well saturated with water, left in contact with the os for twelve hours. Ten or fourteen days afterwards a milder caustic should be applied. In rare cases a second application of the strong acid may be found necessary, but a month at least should intervene, for fear of closure of the canal.

In menorrhagia, from congestion or subinvolution, or where the uterus is too tender to bear the pressure of a hard pessary, or in obstinate leucorrhœa, it is of great benefit to carry the application to the body of the uterus. The author is very partial to this application, and states that he has observed no worse symptoms arise from it than after milder ones.

In one case severe perimetritis followed the application of the solid stick of nitrate of silver to a granulating os. Its prolonged use is apt to produce a hard, gristly cervix, or a contraction, or even a closure of the canal. When the os is everted or very patulous it may be used. An easy method is to heat the aluminium probe, and then dip it into nitrate of silver; a thin film will be formed, and the probe can be carried up to the body of the uterus. This application is very liable to produce uterine colic. In stubborn cases of amenorrhœa, advantage may be taken of its tendency to excite hæmorrhage.

Respecting the use of the ethereal tincture of iodine, there is a fear of the vapour passing up the Fallopian tubes and into the peritoneal cavity if it be applied to the cavity of the uterus.

Vaginal injections should not be omitted during these applications. A very excellent one is a saturated solution of chlorate of potash; suppositories of tannic acid, and acetate or iodide of lead, are considered still better.

In obstinate congestions, drachm-doses of the liquid extract of ergot should be used, either as suppositories *per rectum* or as starch-clusters. Suppositories are preferred to vaginal injections, as the

* Reprint of articles published during January and February, 1874, in the *Philadelphia Medical and Surgical Reporter*.

latter are carried up into the uterine cavity either by capillary attraction or reversed peristaltic or suction action of the uterine fibres. Caustic applications should not be made more frequently than once a week, and only continuous about four to six times. There should then be a rest of nine or ten weeks; this affords an opportunity for impregnation. Conjugal relations should be moderate.

Local Depletion should be always performed whenever the cervix is crimson. Through the difficulties attending leeching, puncturing with a Butler's spear-pointed scarificator is recommended. The puncture should be from one-eighth to one-fourth of an inch deep, and a slight twist of the hand should be given, to enlarge the opening, when withdrawing the instrument. Before repeating the operation a short time should be allowed to elapse, as sometimes the bleeding may be excessive. Whenever the uterus is hypertrophied, or the uterus is tender, or unable to bear the pressure of the pessary, or when the pelvic pains resist ordinary treatment, or in flexions or dysmenorrhœa, depletion will be found beneficial. Its repetition at intervals of a week or two, until the symptoms are relieved, will be found sufficient.

General Treatment.—It is a cardinal rule that iron should be given unless contraindicated. To this may be added, when the uterus is hypertrophied or congested, ergot, quinine, arsenic, and bromide of potassium. Whenever cod-liver oil or syrup of iron has been tolerated, the author has invariably found that the case did well. Several excellent elegant formulæ are given. Patients should never be allowed to dwell on their ailments. The corset should be discarded, and the clothes supported by shoulder straps.

Retroversions and Flexions.—Hodge's pessary is used when there is no undue lengthening of the womb. Ring-pessaries are condemned as tending to overstretch the vagina laterally, and so impair the tonicity of this great supporting column of the uterus. They are also very liable to eat into the vagina and rectum. Again, when made of inferior India-rubber they will crack, and, through rusting of the wire, spring open and cause much injury.

A modification of Hodge's pessary, made by narrowing the anterior part, and bending it so as to be at right angles with the shaft, is most strongly recommended in retroversions or flexions. Should the body of the womb be too tender to bear the hard India-rubber pessary, an air one is advised, coupled with local depletion, and the intra-uterine application of carbolic acid as an anæsthetic, together with a warm douche. The pelvic pains are much relieved by a suppository at bed-time of a grain of morphia and two grains of belladonna. An occasional stretching of the utero-sacral ligaments by the repositr will be found advantageous. In redressing an uterus, care should be taken to push it up laterally, so as to avoid the sacral promontory, which may be done *per rectum* or *per vaginam*, pulling the cervix down at the same time with the volsella. In retroflexion, the uterine dilator appears likely to be of much benefit in obstinate cases.

The writer speaks in the highest terms of praise of the volsella. It is used for redressing or straightening out any version or flexion; in versions the reverse lip is seized to the name of the version, in flexions the same lip, as its object is to stretch out the side flexed. For applying sponge-tents it is of great advantage, and when the cervix is dilated the uterine

cavity is rendered more easy of exploration than by the usual method of suprapubic pressure, which is always painful, and in fat women almost impossible.

Anteversions and Flexions.—As these conditions are more or less the normal ones, it does not follow that certain hysteric or congestive phenomena are to be attributed to these causes, and the patient subjected to uterine treatment, when it might be only moral or a constitutional, or at most, ovarian treatment that was needed. The ovaries are believed to be too frequently overlooked, and their paramount importance in certain conditions disregarded. Without committing himself to the theory that hysteria is primarily or secondarily always an ovarian expression, the writer considers it pre-eminently an affection of the unmarried, newly married, or sterile. The diagnosis is not always clear; but when there is dysmenorrhœa and the uterus is tender or congested, and in addition the marriage is unfruitful, hysteria and other subjective symptoms may be referred to the uterus proper as the primary cause. The vesico-uterine folds should be stretched out occasionally, but not oftener than once a week. Tents of sponge, of lamina, or of slippery elm-bark, may be used as auxiliaries coupled with local depletion. In this affection pessaries are not well borne. Thomas's anteversion pessary may act in certain cases well, but of all forms the inflated ring-pessary will be found most successful. It acts by pushing the fundus off the bladder. Its great faults are over-distension, collapsing, and becoming offensive.

Intrauterine stems are not encouraging in their results; occasionally they set up much inflammation; their use requires so much watching and anxiety that the author has almost discarded them. Hewitt's modification of Hodge's pessary has given more than once great comfort. The chief means of cure is the rapid dilatation of the cervix.

Rapid dilatation of the cervical canal, a method which, in Dr. Goodell's opinion, bids fair to revolutionise the treatment of many uterine disorders, is performed by him by means of an instrument not unlike a strong pair of dressing forceps, but so constructed that a closing of the handles causes a divergence of the blades. Preference, however, is given to Dr. Ellinger's (*Archiv für Gynäkologie*, vol. i. part 2, 1873) as a more perfect instrument; from the length of the blades being limited to two inches, it is free from the danger of slipping into the uterine cavity, through which great mischief might arise.

The anterior lip of the cervix is seized by the volsella, and the dilator is passed up at first as far as it will go. Upon gently stretching that portion, the stricture above so yields that, when the instrument is closed it can be made to pass up higher. By this means a canal, barely admitting the finest probe, may be widely dilated in sixteen minutes. When the cervix is cartilaginous considerable force is required, and the constrictor fibres may be audibly heard to rupture. It is a painful operation, and may require the patient to be anæsthetised, but as a rule this is not done. The woman feels sore for a day or two, but no bad results have been seen to follow. The canal does not return to its usual angular or contracted condition; as in all elastic bodies, increase in width diminishes the length, so the cervix becomes shortened and widened, and the plasma thrown out by the submucous lesions tends to stiffen and thicken its tissues.

A solution of chlorate of potash or strong table salt should be injected warm every three hours,

during the waking hours, so as to prevent the secretions from becoming septic, and also to aid the more rapid expansion of the tents. A still safer plan is to introduce the tents the day before the catamenial flow, as the oozing of the blood through a part of the tent washes away the secretions and keeps them from becoming foul.

W. C. GRIGG, M.D.

(To be continued.)

MENDEL ON THE INSANE POPULATION OF ENGLAND AND OF PRUSSIA.*

The author's chief object is to consider the relative proportions of the insane to the population in each country, and of those under treatment in asylums or remaining in their own houses. In England, on January 1, 1873, there were 60,296 insane persons, or 1 to every 387 of the population, *i.e.* 2.58 per thousand. Prussian statistics are very meagre, but, from results obtained, probably of the year 1871, it appears that there was 1 insane to every 468 of the population, or 2.13 per thousand. The proportion in different provinces was as follows:—in Hanover 1 to 354, in Hessen-Nassau 1 to 348, in Saxony 1 to 534, in Brandenburg 1 to 495. In Berlin itself there is 1 to 820, but a great number, chargeable to the metropolis, are boarded out in provincial asylums. It is pretty certain that there is no real difference in the percentage of insane in the two countries, the population being about the same; and yet in Prussia 7,662 insane persons have been omitted who should have been counted, so bad is the system of registration. The next point is to consider where the insane in the two countries are treated. On January 1, 1873, there were in Prussian asylums 11,460 insane; whilst of the 52,634 insane in December, 1871, as many as 41,174 were either at home or in other families; but in England on January 1, 1873, there were 52,203 in asylums, and only 7,493 with their relatives at home; so that in England 1 out of 442 of the population is sent to an asylum, but in Prussia only 1 out of 2,150. Taking away those whose circumstances are good, and enumerating only those in pauper asylums, it appears that in January, 1873, of 616 persons in this country 1 was in a pauper asylum, and in Prussia 1 out of 2,859! This disproportion appears about the same when Prussia is compared with France. Mendel, however, is of opinion that, even if all the conditions and opportunities that exist in other countries were in vogue in Prussia, there would still be a large excess of those detained at home, because, firstly, the population is more thinly scattered, and hence it is easier for the supervision of an insane person. On examining other countries where the population is very small over a large area, the facts come out as above; thus in Pomerania only one insane is under supervision out of 6,849 inhabitants, and in the Rhine provinces one out of 2,001. The second reason for the difference, as far as Prussia goes, lies in the difficulties existing in getting a pauper into an asylum, difficulties founded not only on the large number of formalities to be gone through, and questions to be asked, but also on the dread of the expenses which are entailed on the parish. As a consequence, it is not easy to get a person into an asylum unless he have set fire to something, or have attempted people's lives. Lunier has

shown that in France, since the late war, motives of economy have influenced the numbers retained in asylums at the public expense. Another reason, apart from the difficulty and expense, lies in the fact that the asylums are overcrowded, and hence hundreds are kept at home in conditions disgraceful and injurious, whilst recent cases cannot be admitted and hence become chronic or incurable. The terror of asylums still existing in many persons' minds is a great impediment to the early reception of cases; but, as the advantages of the non-restraint treatment and of the humanity shown in these buildings become better known, such scruples are more likely to disappear. Berlin may well set the example to the rest of Prussia, for out of 1,339 of the population there is only one in an asylum.

In eight years the increase in the numbers placed in Asylums has been 19 per cent., whilst the population has only increased 5 per cent. The excess is due to the reckoning of old cases, who are transferred to the asylum from the families in which they were located, because it was no longer possible to keep them. In Prussia there are 1,490 private patients in public asylums, and Dr. Mendel remarks that it seems wrong in the face of the universal complaint of the overflow of asylums, and of the great need of protection of pauper patients, to fill asylums with these private patients.

Dr. Mendel next considers the modes of treatment, medical and otherwise, in vogue in England and Prussia, not regarding the workhouses. In both there is still need (as the reports of the commissioners show), of improvement in the diet, attendance, and medical treatment. In the English county asylums cleanliness and neatness are supreme, and these are only in any degree rivalled by the Swiss asylums. Not only does this apply to the corridors and rooms, but to the dress of the patients. Germany is far behind in these respects, owing chiefly to the use of old buildings for purposes for which they were never intended. However good the administrative arrangements may be in England, the same cannot be said for the medical treatment. To Dr. Mendel it seems that knowledge of the individual patients seems wanting, but he hastens to say that the blame does not rest with the medical men, and that any one placed in their position would, however conscientious he may be, act in the same way. The chief reason lies in the small number of medical men to the patients, the proportion being about half those in Germany; and whilst the latter are not troubled with clerk's work, the former are encumbered with the filling up of forms, etc., and their time is taken up by a considerable number of visitors of different degrees of authority, such as Committees, Lunacy Commissioners, etc. It is to this overcrowding with work and the scarcity of medical element that much of the restraint still to be found is due. He points to the fact that of late years restraint had made a fresh start in the largest English Asylum, Colney Hatch, and then gives in detail the remarks of the Commissioners in Lunacy on its abuse and Dr. Sheppard's replies. He is in favour of 'seclusion,' and thinks that it often works better than medical sedatives. As to the amusements, concerts, etc., which are so largely supplied by us to the patients, he thinks them injurious, and still more, that it is a positive wrong to keep a 'large and spacious hall set apart for these things, where corridors and passages are utilised for persons who should be otherwise accommodated.' All these entertainments, Dr. Mendel holds, are for the attendants and

* An Address given before the National Science Assembly at Wiesbaden. (*Archiv für Psychiatrie*, 1874.)

the invited guests, the public, since they are unnecessary for the curable cases, and are not comprehended by the chronic and incurable. These remarks, however, do not apply to such amusements as billiards, bowls, etc., which serve a really useful purpose. The work done in the different departments in the Prussian and English Asylums is compared, favourably to Prussia. The most important phrase is the concluding one, viz. :—that for scientific and rational treatment a positive knowledge of each case is necessary, and that the English system is incomplete in this particular and behind other countries, inasmuch as the medical element is too small and cannot exercise its proper functions because of the mass of lay work imposed on it.

[Dr. Mendel is correct in his remarks about the insufficiency of medical men to the numbers in this country, but we think he scarcely does justice to the committees. It is important, indeed the public would not be satisfied otherwise, that the great powers of expenditure and liberty over the persons of the inmates which are confided to the Medical Superintendents should be supervised and checked. No man is infallible, and there is much less risk of mistakes when men of large intercourse with the world are introduced as the cushion between the medical element and the public. The committees, as a rule, are composed of men who give a deal of time to the affairs of the institution and accept much of the responsibility, and many superintendents are very glad to have the responsibility of such items as making contracts, forming settlement of legal claims, &c., taken off their hands. Besides, few medical men have the knowledge necessary to conduct the administrative affairs of a large asylum. It has long been a reproach to the medical superintendents of asylums in this country that they are stewards rather than physicians, and Dr. Mendel seems to have been imposed upon by some one who misinterprets the true position of medical authority in asylums, and who would, in his anxiety to usurp every function of power in the place, leave for himself still less time than he now has for treating patients, and for making those scientific investigations for which asylum physicians are not, as a rule, noted.—*Rep.*]

T. C. SHAW, M.D.

EPIDEMICS OF CHOLERA IN FRANCE.

(Continued from page 419.)

Here arises the question, What is cholera? Whence comes it? What is its origin? How is it developed? Cholera, such as in former times prevailed in France, is a new disease in Europe, and *sui generis*; nor does the history of epidemics afford an exact description of the disease as it has been seen there. Notwithstanding the identity of the name with epidemic cholera, the sporadic is essentially different from that disease, both in its nature and in its great severity. The one is deadly, the other benign; the relative severity of the two being compared to the sting of the Indian scorpion and that of Europe. The sporadic form—the product of causes easily appreciable, as for example, cold drinks during the hot season—is altogether of an individual character, and by no person believed capable of being communicated by the subject of attack to another. The epidemic form is often developed without the presence of sufficient appreciable cause, affecting a large number of persons and

places, under hygienic conditions the most diverse, and often transmitted from one individual to many others.

1. It is universally admitted that India is the home of the disease, especially the districts near the large rivers, as plague prevails in the delta of the Nile, and yellow fever at the mouths of the Mississippi. According to one set of pathologists, cholera is the product of a special miasma originating in India, transported into Europe across continents and seas by atmospheric currents; according to others, cholera is produced on the spot where it shows itself, being engendered by accidental local conditions, such as are called epidemicity, and multiplying by the action of special causes on the mass of the population; a third class consider that cholera, originating in India under particular conditions of climate, propagates itself to long distances, transported by man, and multiplying by successive transmission, favoured by accidental causes.

In opposition to the first theory, various objections of great weight are adduced. The exhalations from the Pontine marshes do not produce fevers at a great distance from their source. Let us therefore admit for the effluvium of cholera a power even a hundred times greater, it would be insufficient to account for its transport to a distance of four or five thousand leagues from its point of origin. Is it admitted that the miasmata become multiplied in the atmosphere? How are we to understand that effluvia, arising in India in 1817, and carried by the atmosphere, required fifteen years to traverse the 2,500 leagues which separate the banks of the Ganges and those of the Seine? What slowness, when hurricanes traverse the breadth of France in one day! How does it happen that these miasmata propagate themselves in different directions?—that from the Bay of Bengal they extend eastward to Sumatra, Borneo, and China; southward to Ceylon, Malabar, and Mauritius; northward to Tartary; north-west to Persia and Egypt, and thence across Russia and Europe? How are we to explain the circumstance that, in 1832, cholera passed from Germany to London without affecting Belgium; passing also from London to Paris while strong north-east winds prevailed, and with a clear sky? It is said in reply, that in the higher strata of the atmosphere there are currents which proceed in an inverse direction to those that are apparent. The supposition is gratuitous. And according to the committee, the epidemic was carried by travellers, fleeing from their foggy country, already infected, to enjoy the advantages of Paris until that time free from the disease. How also are we to explain that never, in any country, has the extension of cholera coincided in a definite manner with the direction of the prevailing winds? How are we, according to the theory of transport by the atmosphere, to account for the singular tendency of the disease towards certain great cities in different epidemics? Thus, in 1832 Calais was first invaded, then Paris: in 1849, Douai, and immediately afterwards Paris: in 1853, the department of Aisne, and Paris within a few days: in 1865, Marseilles and Toulon, then Paris—always Paris. What is the situation of Paris in regard to all currents of wind from east, north, north-east, and south? Is it not rather that there is always a stream of the population itself towards the great social centre of France. It has been stated that cholera has often appeared to extend along the course of streams and rivers, and it has been supposed that this arises from the contamination of the air from the beds of those streams and

rivers. But experience teaches that cholera as often ascends along the course of a river as descends by it. Moreover, is this to be explained by the circumstance that habitations are generally most thickly placed along the vicinity of rivers? If the epidemic were conveyed by the atmosphere, it might be supposed that the influence would descend suddenly upon a number of places in the interior of a country like a shower of hail. Instead of doing so, it invariably enters from the borders, most frequently from a sea-port. How again, supposing that it were conducted in the form of a miasmatic cloud, is it to be supposed that that cloud would remain during three months extended over a city, as for example in the case of Amiens? How, on the same hypothesis, are we to account for the epidemic being limited to one district, one street, or even one range of buildings?

2. Against the theory according to which cholera is generated upon the spot where it appears, various objections are adduced. The precise causes and conditions under which under such circumstances the disease is produced, are left undefined. Are its causes looked for in special conditions of the atmosphere of the locality? The conditions showing the prevalence of an epidemic are precisely similar to what they are in its absence. Is it high temperature? In 1846 and 1863 the heat was 36° and 39° Cent. (97° Fahr. and 102° Fahr.); yet no case of cholera occurred. If a high temperature favours the development of cholera, it cannot be looked upon as its cause. In the last epidemic at Cherbourg, the greatest intensity of the disease occurred in the months of January and February, 1866; and during 1830-31 it prevailed at Moscow in the winter season. Is humidity or dryness the cause? Dryness was extreme in 1846, humidity in 1852, yet cholera did not prevail in either year. Is it variations in the state of atmospheric electricity? If so, in what are they different from such as take place many times without the appearance of cholera? Nothing positive on this point has been ascertained. Are the causes to be found in a changed condition of the constituent principles of the air, a diminution of ozone? Decrease of ozone occurs every summer, and the supposed changes in the constituent principles of the air have never been detected by analysis. Do the causes exist in the constitution of the soil? If so, the soil of France has undergone no change during the last thirty-five years—has been subject to no cataclysm. Have we not also seen cholera prevail in regions having the most various geological constitution? Low, damp or marshy alluvial localities near marshes, or infected streams favour the development of cholera, but are not sufficient always to produce it. Thus in some places, localities seemingly the most unhealthy have been respected, while others, to all appearance most healthy, have been ravaged by it; in the same department, arrondissement, or canton, certain villages ravaged in 1854 had escaped in 1849, and nine which had been free in 1849 and 1832, suffered severely in the later epidemics. Such conditions are very secondary. They may, and do have an influence upon the multiplication of cases of the disease, but none of these conditions, nor the union of several, have ever given rise to the disease. Do we invoke a combination of hygienic conditions, such as want of sufficient space, clothing, air, light, or food, bad water, excesses of all kinds, mental depression, overcrowding, and so on? All these favour the development and multiplication of the disease, but

no one or combination of them can produce the disease. To go no farther back than 1792, have there existed no bad conditions since then? Had we not at the beginning of this century, throughout Europe, grand movements of armies, engagements, and battles, notably in 1813 and 1814; great military disasters, precipitate retreats, with their fatigues and privations, endured by coalesced Europe, great dryness, great humidity, scarcity, famine, typhus, and other evils?—yet in the midst of all these no case of cholera occurred.

3. As to the theory that cholera, originating in India, was imported and propagated by man, its partisans present the disease as following the great lines of communication by land and by sea. In the first great invasion, for example, they trace it from India, where it is said to have sprung up in 1817, advancing across the continent of Asia by the route of caravans and armies, traversing in succession Prussia, Russia, the north of Germany, and reaching France in 1832. In the latest invasion, on the contrary, it was observed quitting India in the early months of 1865, advancing towards Europe by sea, and reaching Marseilles in June, that is, less than six months from the time of its starting. On the first occasion it took fifteen years to reach France. In the latter it advanced with the rapidity of vessels, requiring only a few months to arrive from Calcutta and Bombay at Mecca, then at Cairo, Alexandria, the shores of the Bosphorus, Catalonia, and Provence. There exists no example, say the advocates of this theory, of the arrival of cholera from one continent to another more rapidly than the progress of travellers, and from a continent across sea more rapidly than the rate of steam-vessels.

When the invasion takes place by land, it is indifferent by what point of the frontier the cholera penetrates. When it arrives from beyond sea, as from Alexandria in 1865, it first arrives in the commercial ports, as happened then in respect to Constantinople, Ancona, Barcelona, and Marseilles, all of which were affected before other places nearer the point of departure. The explosion of the disease also took place on all occasions soon after the arrival of a vessel from the infected country. The partisans of importation, moreover, argue, in regard to the preservation of certain islands and certain establishments, both public and private, which had for a time interrupted all communication with reported localities, or prevented the approach of all vessels arriving from suspected places. Thus, Sicily was preserved in 1865 by receiving no vessel arriving from affected localities; so also Batna, in Algeria, by means of posts of surveillance, which isolated it in the middle of the country ravaged by the epidemic.

In support of the transmissibility of cholera from one person to another, the advocates of the theory adduce many instances where the arrival of one or several persons affected with cholera in a district, until then free from the disease, was immediately followed by a development of the disease among those who had received or attended them; on the other hand, the opponents of that theory only see in these events the occurrence of simple coincidences, or explain them by the intervention of epidemics, which really means *nothing*. Others adduce numerous opposing facts against the theory, giving, as proofs of the non-contagion of cholera, the cases of many persons that had attended patients, slept in their beds, and yet did not take the disease. To this the partisans of transmissibility

reply, that in the instances alluded to negative facts cannot destroy the value of those of a positive kind, as where the transmission of the disease had the character of evidence. At the same time the non-contagionists, while denying the facts brought forward by their adversaries, claim for those adduced by themselves in refutation, the character of being also positive. The partisans of the theory of transmissibility, however, do not assert that cholera is always thus communicated. They admit the necessity of special conditions, without which the transmission does not take place, any more than does that of smallpox, scarlatina, diphtheria, and so on; conditions which, as in the case of typhoid fever, depend partly upon the intensity of the morbid principle, its condensation in a limited locality, the duration of its action, &c.; partly upon the powers of physical and moral resistance possessed by the individuals exposed to contagion, and their degree of susceptibility.

The partisans of epidemicity deny, as a gratuitous supposition, this condition of special aptitude deemed by their adversaries essential for the transmission of the disease; but are they not themselves obliged to admit the existence of a partial predisposition in those attacked by the disease, and also an individual peculiarity in those who resist? How otherwise are we to account for the epidemic influence hovering over a locality only attacking some individuals, and not all? The contagionists believe that the hundreds of instances in which communication has not been traced do not invalidate a single fact of true transmissibility; thus, it is observed in the report, the cases of three medical men, whom they name, as having contracted fatal attacks of diphtheria from patients, prove the communicability of the disease, although many others who attend patients suffering from it altogether escape. One of the arguments long used against the communicability of cholera is the large number of medical men who in the first epidemic pronounced against it. This has, however, been abandoned in subsequent epidemics, and shown to have no value. Even in 1832 there were some who believed in the contagion of the disease; they became more numerous in 1849, became predominant in number in 1854, and after 1865 there remained only a few opponents in the field. To refute the communicability of cholera, an argument is drawn from the small number of 'sisters,' students, and *infirmiers*, who became attacked with the disease. It may be said, in reply, that if the number of medical men and sisters is less considerable, this is to be explained by the moral power, and consequent resistance of these, to their sentiment of duty, and to their habit of struggling with disease; others refer this relative exemption to the solidity of their faith and their Christian resignation. It is asserted, on the other hand, that this pretended exemption is only an error. In 1849, at the Salpêtrière, the director, two *internes*, several attendants and *infirmiers*, succumbed, while a number of the medical men and *employés* were severely attacked. In 1865 eleven medical men died of the disease at Ancona, three at Paris in 1866, three medical men and thirty sisters at Amiens in the same year.

It still remains to explain the occurrence of many cases where persons have been struck at the same time and at places distant from each other, without having had any communication with other subjects of the disease, when there could have been no transmission by contact. According to the partisans of

transmissibility, if cholera requires immediate contact with a patient suffering from it to be thus caused, it is communicable to a greater or less distance, according to circumstances, by the emanations from patients.

(To be continued.)

ANATOMY AND PHYSIOLOGY.

FOSTER ON ENDOTHELIUM AND EPITHELIUM.—Dr. Michael Foster (*Quarterly Journal of Microscopical Science*, July, 1874) observes that the word 'endothelium' has been recently introduced into histology, and the use of it has rapidly become common, if not general. The speedy acceptance of a new term may, in many cases, but not in all, be taken as an indication that something of the kind was wanted; and the already frequent use of 'endothelium,' both by Continental and English histologists, would seem to show the need of some other phrase besides 'epithelium.' Nevertheless, there are cogent reasons why the new term should not be allowed to take any further root.

In the first place, Dr. Foster says, its etymology is of the most grotesque kind. This is of course an objection of secondary value; but still it carries some weight. When a term has come into daily use, with a clear, well-defined meaning attached to it, it does not matter much what its etymology is or how it is spelt, except on historical grounds. Many terms become so altered in their meanings before they finally acquire a permanent application, that the chief interest in their etymology is confined to the light it throws on the ideas of the man who first introduced them. This is the chief reason why new terms should be etymologically correct, in order that future inquirers may read back through them into the minds of earlier observers. When a word is etymologically pure nonsense, this is apt to become impossible. Such is the case with endothelium.

It appears to have been first introduced by His, to designate the kind of epithelium (pseudo-epithelium, '*unächte Epithelien*') which is found lining the vascular, lymphatic, and serous cavities of the body, in contradistinction to the real epithelium of mucous membranes. He says (*Die Häute und Höhlen des Körpers, Akademisches Programm*. Basel, 1865, p. 18):

'Alle die Zellenschichten, welche den Innenräumen des mittleren Keimblattes zugekehrt sind, zeigen nun aber unter sich so viel Gemeinsames und sie differiren von der ersten Zeit ihres Auftretens auch so erheblich von den Zellenschichten, die aus den beiden Gränzblättern hervorgegangen sind, dass man, im Interesse physiologischen Verständnisses wohl thun wird, sie von diesen durch eine besondere Bezeichnung zu scheiden, sei es, dass man sie als *unächte Epithelien* den *ächten* gegenüber stellt, sei es dass man sie *Endothelien* nennt um mit dem Wort ihre Beziehung zu den innern Körperflächen auszudrücken.'

Endothelium is here contrasted with epithelium, so that the latter may be considered as the 'thelium' of free surfaces (whether invaginated or not), and the former as the 'thelium' of internal closed spaces; 'thelium' apparently being taken to mean 'a layer or layers of cells.'

Now, what is the derivation of 'epithelium'? I am indebted to Dr. Sharpey for the following account.

He says, in a letter to me:—“*Epithelium*, or rather “*epithelida*,” and especially “*epithelia*” (first declension), was introduced by F. Ruysch. In describing a preparation of the face of a child finely injected, he refers to the cuticle over the red part of the lip (prolabium), and says, “I cannot call this ‘epidermis,’ seeing that the subjacent tissue is not skin, but a different substratum covered with sensitive (nervous) papillæ, which are finely injected.” He then goes on to say that as the cuticle lies on papillæ he will call it *epithelida*, or *epithelia*, from $\epsilon\pi\iota$ and $\theta\eta\lambda\acute{\eta}$, “papilla” or “mamilla,” and he adds that for the same reason he calls the inside coating of the cheeks by the same name. The original is as follows (Ruysch, F., *Thesaurus Anatomicus*, III. no. xxiii. p. 16).

“... Nulla subest huic integumento cutis, ergo epidermis dici nequit, quamvis analogiam summam et connexionem cum illâ habet comperi probalia constituta esse ex meris papillis non cutaneis cutis enim hic reverâ deest) sed papillis nervosis; itaque integumentum illud supradictum potius epithelida dixerò vel integumentum papillare prolabiorum, quod reverâ nil est nisi efflorescentia seu expansio extremitatum papillarum.”

‘In *Thesaurus Anatomicus* VI. no. cxv. p. 49, he says, “Anterior pars prolabii inferioris—*epithelia* adhuc est obducta.”’

From this it is evident that epithelia (changed in course of time into epithelium, just as platina has become platinum), means ‘that which covers or is upon a papilla,’ and consequently endothelium means ‘that which is inside a papilla.’ The extension of the phrase epithelium to the cellular covering of such parts of the corium as are destitute of papillæ may be easily allowed, but it does seem a most daring defiance of all meaning of words to apply the phrase ‘within the papilla’ to the cells coating surfaces of which one great characteristic is that they are devoid of papillæ! There seems to be something attractive about ‘thelium’ that tempts writers to make use of it. Already endothelium has given rise to a new ‘ectothelium,’ and probably after a few years ‘thelium’ will become a sort of histological maid-of-all-work, with as many prefixes as there are kinds of cells.

In the second place, there are objections to the use of endothelium not etymological in their nature.

The peculiar views of His on the origin of the connective tissues of the body would, if true, afford a strong argument for the use of some special term to denote such kinds of epithelium as were formed out of his parablact. Putting these aside as mistaken, there still remains the question whether it is not desirable to have some distinctive appellation to denote the epithelium which is formed out of the elements of the middle of the three layers of the germ (the *mesoblast* of Mr. Huxley and myself), the word epithelium itself being reserved for the nether layer (or *hypoblast*).

If so, the word endothelium cannot be employed with this meaning, for it would then include structures still called epithelium, and differing in no essential characters from the epithelium derived directly from the hypoblast.

The cells lining the Wolffian duct, and its derivative the ureter, with their branches, would then come under the heading endothelium. Whatever be the exact mode of the first formation of the Wolffian duct, whether by the central solution of a solid ridge, or by an infolding of the lining of the pleuro-

peritoneal cavity, it is lined by cells which are clearly mesoblastic in origin, not hypoblastic nor, as was once suggested, epiblastic.

The case of Müller’s duct is still more clear. This undoubtedly arises by an infolding of the lining of the pleuro-peritoneal cavity. Its epithelium is distinctly mesoblastic in origin. The germinal epithelium which gives rise to the ovaries is also essentially mesoblastic.

If the word endothelium, then, be taken to denote an epithelium derived from the mesoblast, it must be extended to include the epithelium of the Wolffian and Müllerian ducts, and of the parts which are formed ultimately out of those structures. But if these be included, the phrase loses all its practical utility. If they are excluded, all the little meaning it ever had vanishes.

It may be urged that we need a word to denote the epithelium which is found in the vascular and lymphatic spaces. There does not, however, appear to be sufficient reason why the same term should be applied to the whole of this epithelium. As we have seen, its common mesoblastic origin will not justify this. From a structural point of view, three distinct varieties may be recognised in it, viz. the spindle-shaped cells of the blood-vessels and larger lymphatic vessels, the sinuous cells of the commencing lymphatics, and the polygonal cells of the large serous cavities. The fact that the epithelium of the peritoneum is continuous with that of the lymphatics affords no argument whatever for classing them together. We find continuity everywhere. The epidermis is continuous with the alimentary epithelium, and with the urinary and generative epithelium; and the generative epithelium is in turn continuous with the peritoneal epithelium. In short, there is no reason why the cells spoken of as forming endothelium should have a common title, distinct from the general term epithelium.

The introduction of the new term is really a step backwards from, instead of an advance beyond, the old classification adopted by Dr. Sharpey in Quain’s *Elements of Anatomy*. He divides epithelium either physiologically into epidermic, mucous, glandular, vascular, serous, &c., or structurally into columnar, spheroidal, ciliated, tessellated, squamous, &c.

Surely some such nomenclature as this satisfies all requirements, either morphological or physiological, at least for the present.

The chief morphological importance, as far as our knowledge goes, attaches itself to the question from which of the three primary layers any given epithelium is derived, whether from epiblast, hypoblast, or mesoblast; and it is precisely because the phrase endothelium is in this respect misleading that its use is undesirable. Beyond this, it is difficult to see any morphological interest, unless future research should show that in the common mesoblast there are factors morphologically distinct. When that is clearly shown it will be time to invent new terms which may be as lasting and as valuable as ectoderm and entoderm.

For physiological purposes all we need is some system of phrases which shall clearly indicate the individual characters and the arrangement of any group of cells. The few terms, ‘columnar’ or ‘cylindrical’ and ‘spheroidal,’ either ‘ciliated’ or ‘non-ciliated,’ are almost all we want for mucous membranes in general. The word ‘squamous’ sufficiently clearly indicates the general character of an epithelium made up of flattened cells which overlap, as

'tessellated' equally clearly signifies an epithelium of flattened cells fitting into each other at their edges. These are general distinctions. Such special forms as the sinuous cells of the commencing lymphatics or the jagged cells of the epidermis do not need any distinctive general appellation.

We perhaps do want easy terms which shall denote whether the epithelium in any spot consists of several layers, or of one pronounced layer only. The latter might be called *monoderic* ($\delta\epsilon\rho\omicron\varsigma = \delta\epsilon\rho\mu\alpha$), the former *polyderic*.

Epithelium itself would simply mean cells lining a cavity or coating a free surface.

RANVIER ON THE DEVELOPMENT OF BONE-TISSUE.—A note on this subject was read by M. Ranvier before the Académie des Sciences, November 27, 1873.

To study the growth and development of bone-tissue, Ranvier uses the bones of the embryo, which are placed in absolute alcohol for twenty-four hours, having previously been freed of the surrounding soft parts (except the periosteum). After that, they are transferred to a saturated solution of picric acid, in which fluid they are kept until they become soft enough to be fit for sections. In order to make thin and successful sections, the softened bone is plunged into a thick solution of gum arabic for forty-eight hours, and then into alcohol of forty degrees. Now it is easy to obtain very uniform sections through all parts of the bone, *z.e.* bone-matrix, medulla, and periosteum. The sections having been washed in distilled water for twenty-four hours or more, in order to dissolve the gum, they are stained with picrocarminate of ammonia, and finally mounted in glycerine. In a longitudinal section through a long bone of an embryo of a mammalian animal, passing from the periosteum towards the axis, it is easy to see a well-marked boundary between the periosteal bone and the cartilaginous bone. The latter occupies the centre, and has an hour-glass shape in the longitudinal section, whereas the periosteal bone forms on each side a semilunar mass. The long bone at this stage of development may be correctly compared to the following scheme: an hour-glass shaped cartilaginous bone is suspended in a cylindrical tube—the periosteum; that part of the space of the tube which is not occupied by the former is filled out by periosteal bone. This arrangement, although not found in all stages, is always present in a certain stage of the development of the bone. If one examine in a longitudinal section above mentioned the line of ossification, which represents at the same time the boundary between the cartilage and bone, there is found at the extremities of that line a notch penetrating into the cartilage. It is very easily understood that this notch represents the transverse section through a circular groove. From the convexity of this notch ('*encoche d'ossification*'), fibres take their origin, which, at their basis, being identical with the matrix of the cartilage, bend round to the side of the embryonal bone and penetrate into the latter. These fibres, which Ranvier calls '*fibres arciformes*,' become in time identical with those fibres known as Sharpey's fibres. Amongst the mammalian animals, the embryonal bones of sheep are best suited for the study of those fibres. As soon as these fibres have left the cartilage, they appear to be separated by rows of spherical or slightly polyhedral cells, which Ranvier believes to be derived from cartilage-cells after their capsules

have become opened. These cells gradually assume the characters of osteoblasts, and they lie all along the arched fibres, the latter becoming covered with bone-substance, and thus representing the first traces of subperiosteal bone. The arched fibres represent the directing fibres of the ossification; they can be recognised in the interior of the bone in transverse sections, where they appear as small dotted circles in the systems of the intermediary lamellæ.

On the external surface of that part of the cartilage belonging to the '*encoche d'ossification*,' a primary osseous lamella is formed, which Ranvier calls the perichondral bone-crust; it forms later on the boundary between the cartilaginous and the periosteal bone. E. KLEIN.

KOHTS ON COUGHING.—Dr. O. Kohts (Virchow's *Archiv*, vol. lx. Heft 2, p. 191) for his experiments upon this subject, used cats and dogs. Neither the position of the glottis nor diaphragm were directly observed; the author, like Nothnagel, drawing his conclusions from the occurrence or non-occurrence of the characteristic detonations during coughing. The animals were in no case narcotised. For the production of coughing the author employed mechanical stimulants, feathers, pinching, teasing, squeezing with forceps; chemical irritants (common salt and ammonia), thermal (ice) and electrical stimulants. From his experiments the author draws the following conclusions.

By stimulation of the centripetal fibres of the pneumogastric nerve, reflex coughs are produced, and this is proved experimentally:

1. For the trunks of the pharyngeal and superior laryngeal nerves of the pneumogastric;

2. For the peripheral endings of the pneumogastric nerve in the following areas. Coughing occurred:

(1.) On stimulation of the mucous membrane of the pharynx, of the larynx (of the fossa interarytænoidæ, of the plica glossopiglottica and plicæ ary-epiglotticæ), of the trachea, of the bifurcation of the trachea, and of the bronchi:

(2.) On stimulation of the costal pleura:

(3.) On stimulation of the œsophagus (the experimental proof for a so-called stomach-cough is wanting).

3. There is a central cough which can be produced by direct stimulation of the medulla oblongata (*vagus*). WM. STIRLING, D.Sc. (Edin.) M.B.

SCHÄFER ON THE INTRACELLULAR DEVELOPMENT OF BLOOD-CORPUSCLES IN MAMMALS.—At the meeting of the Royal Society, March 19, Mr. E. Schäfer contributed a paper, of which the following is an abstract (*Medical Microscopical Journal*, June 1).

If the subcutaneous connective tissue of the newborn white rat be examined under the microscope in an indifferent fluid, it is found to consist chiefly of an almost homogeneous hyaline ground-substance, which is traversed by a few wavy fibres, and has a considerable number of exceedingly delicate more or less flattened cells scattered throughout the tissue. The cells here spoken of are, of course, the connective-tissue corpuscles. Their branches as a rule are few and short, and they are mainly distinguished by the extraordinary amount of vacuolation which they exhibit—by which is meant the formation within the protoplasm of minute clear spherules, less refractive than that substance, and probably, therefore, spaces

in it containing a watery fluid. The nuclei, of which there is generally no more than one in each cell, are frequently obscured by the vacuoles; but when visible they are seen to be round or oval in shape, and beautifully clear and homogeneous; they commonly contain either one or two nucleoli. It is from these cells that the blood-vessels of the tissue are formed, and within them red, and perhaps also white, blood-corpuscles become developed. Of the vacuolated cells above described, some possess a distinct reddish tinge, either pretty evenly diffused over the whole corpuscle or in one or more patches, the edges of which are shaded off. Others contain either one, two, or a greater number of reddish globules, consisting apparently of hæmoglobin. These vary in size from minute specks to spherules as large as, or even larger than, the red corpuscles of the adult; in cells which are apparently least developed, it is common to find them of various sizes in the same cell; whereas cells which are further advanced in development are not uncommonly crowded with globules of hæmoglobin, tolerably equal in point of size, and differing from the adult corpuscle only in shape. It is important to remark that there is at no time an indication of any structure within the globules resembling a nucleus; the nucleus of the cell also appears up to this point at least to undergo no change. In fact, the formation of the globules of hæmoglobin reminds one rather of a deposit within the cell-substance, such as occurs in developing fat-cells, the difference being that in the latter case the deposited globules eventually run together into one drop, whereas in the former they remain distinct as they increase in size, and eventually take on the flattened form. Before, however, this change occurs in the globules of hæmoglobin, the cells containing them elongate, and are soon found each to contain a cavity, within which the globules now lie. This cavity is probably formed by a coalescence of the vacuoles of the cell. The cell now comes to resemble a segment of a capillary, but with pointed and closed extremities; it is of an elongated fusiform shape, and consists of a hyaline protoplasmic wall (in which the nucleus is imbedded) enclosing blood-corpuscles in a fluid—in fact, blood.

CZERMAK ON HYPNOTISM IN THE CRUSTACEA.—In a paper published in the *Sitzungsberichte der Wiener Akademie* (Band lvi. Heft 3, 4, and 5) Professor Johann Czermak relates some curious hypnotic effects he has observed in certain crustacea. His attention was drawn to the circumstance by a paper in which it was stated that if the ordinary crayfish were held firmly in the hand, and some magnetic passes made down its back, care being taken not to touch it, the animal soon became quiescent, and would permit itself to be placed on its head, where, if balanced by its nasal spine and chelæ, it would remain for a considerable period. On being unmagnetised, so ran the report, by reverse passes, the animal again resumed its activity. Professor Czermak was induced to study these phenomena a little more closely, and soon found that the magnetic passes had nothing to do with the phenomenon; but the fact remained, that if the animal were firmly held, in spite of some struggling, with its head downwards for some time, it gradually became quiescent, and would long continue balanced in the mode above described, as though it were asleep. The mere retention of the

animal upon its back, the first struggling movements being prevented, was followed in the same way by a period of quiescence of considerable duration, from which the creature awoke either spontaneously, or on the application of a strong stimulus. Further experiments showed that all active movements and response to ordinary stimuli, could be prevented in the crayfish by keeping it forcibly quiet for a time, either by binding it, or by fastening it between wooden pincers. Czermak made some experiments corroborating the well-known action of a chalk line drawn from the beak forwards, or from both eyes outwards, on fowls, and which he says struck him with the utmost astonishment when he first observed its effects, the fowl remaining breathing violently, but perfectly quiet and incapable of reacting to ordinary stimuli. He found, however, that the chalk line was unnecessary, all that was required being to restrain the animal's efforts at escape on being first caught, and then quietly to stretch the neck and put the head in contact with the ground. By this means not only fowls, but geese, ducks, turkey-cocks, and swans, could be rendered quiescent, and apparently made to lose all voluntary control over their movements.

BÉCHAMP ON CASEIN AND ALBUMIN.—Commaille finds for casein dried *in vacuo* the formula $C^{108}H^{97}N^{14}O^{29}$, 5HO, the five equivalents of water of hydration being disengaged at a temperature of 150° ; on the assumption that the molecule of casein remains unaltered at that degree of heat, which M. Béchamp has found not to be the case. Pure casein, of which the rotatory power was constant at 109° , was completely dried *in vacuo* at the ordinary temperature. Under these conditions the substance dissolves easily in a very dilute solution of caustic soda, or of sodic carbonate. The quantity of caustic soda necessary and sufficient to dissolve 100 parts of casein dried *in vacuo* is 1.4 parts. At 140° casein, in contact with air, has been found to have lost 2.84 per cent. after three hours' heating. The residue, treated with an alkaline solution, even to a certain degree of concentration, is not entirely dissolved, to 50 per cent. The insoluble portion, washed with a large quantity of alkaline solution, then with pure water, swells up into a transparent jelly that contracts considerably upon desiccation. Casein is then alterable by the action of heat. This substance also the author finds to fix nearly a third of its weight of acetic acid. Butyric acid combines easily with casein, and the compound retains that acid at 140° .

The albumen of white of egg unites also with acetic acid, and the compound, instead of dissolving in acetic acid, as does the casein compound, is insoluble therein.

JOLLY ON THE FERRUGINOUS CONSTITUENT OF BLOOD.—The author, in conclusion of a paper presented to the Paris Academy of Sciences, shows calcination to be a defective method in the analysis of blood when its ferruginous element is sought; that the results vary according to the duration of the operation; that carbonisation in a closed vessel at as low temperature as possible, should be preferred.

PAGET HIGGS, D.Sc.

MR. PIAZZI SMYTH writes to us to say that his paper, forwarded to the Royal Society, to which we lately referred, contained nothing whatever about Melchisedec or divine inspiration.

MEDICINE.

EPIDEMICS OF PAROTITIS.—Three such epidemics are reported in the Statistical Report of the Health of the Navy for 1872, which is just published, in July 1874.

Ninety-eight cases of this affection appeared in the force during the twelve months, the majority occurring in the *Implacable*, the *Impregnable*, and the *St. Vincent*.

There were twenty-one cases of mumps in the *Implacable*. But little information is given in connection with them. In four instances, metastasis to the testes occurred.

In the *Impregnable* there were thirty-seven cases of mumps, with reference to which Staff-Surgeon S. Wade observes: 'Thirty-seven cases of this disease came under treatment. The first appeared on April 20, a well-marked but not severe case; no other occurred till May 6, when two boys came under treatment. After this, cases continued to occur until the beginning of July, the height of the epidemic being about May 26. The long-continued wet weather was the probable cause, and this influence prevailing, both were attacked independently of infection. The boys affected belonged to different parts of the ship, and were not necessarily in close association; those in the sick berth, under treatment for other diseases, were not attacked.

'Both glands were affected in all; in two, metastasis to the testes took place, and in two the testicles were first attacked, the parotids becoming afterwards enlarged. The attacks commenced at first with headache, depression, and the usual symptoms of fever, but not severe in any case. They were all treated on board; a part of the orlop deck was screened off, in which the boys affected were kept in their hammocks. But little medicine was required; a few days' confinement in bed was all that was necessary in most cases. Seven days was the average time under treatment.'

An epidemic of mumps occurred on board H.M.S. *St. Vincent*, and thirty-eight cases were admitted. The difficulty of tracing the first case of a contagious disease to its source is always great. In the attempt made in this instance, every fact was recorded, and every detail regarding the movements of the individual entered upon, but without success. The lad who had first contracted the disease had inhabited a densely populated part of London, and was ignorant of any evil influence being in existence in his neighbourhood. But though this difficulty was pronounced in the attempt to trace out the origin of the first case, no difficulty obtained for the rest; for scarcely had the first boy been on board a few days, before the disease made its appearance among his comrades, and spread rapidly. This epidemic was limited to the Midsummer quarter. Of the thirty-eight cases the right parotid was affected in ten, the left in six, and both parotids in twenty-two. In four of these cases, metastatic enlargement of the left testicle occurred, whilst the right was affected in one.

IRWIN ON ACUTE RHEUMATISM TREATED BY CHLORAL HYDRATE.—The following interesting history of a very severe case of acute rheumatism occurring in a boy of H.M.S. *Cambridge*, is thus given by Staff-Surgeon A. Irwin of the Royal Navy Hospital at Plymouth (*Navy Health Report*, 1874). '.....

aged 16. The boy was admitted from H.M.S. *Cambridge* on November 26, 1872, suffering from acute rheumatism, engaging the wrists, elbows, knees, hands, and ankle-joints, with high temperature, but without cardiac complication. He was treated as has been customary in this hospital, with a mixture containing bicarbonate, acetate, and nitrate of potash, in effervescence; and an alkaline lotion with opium, to the affected joints. He progressed favourably up to December 5, when he became exceedingly restless, and complained of much frontal pain, and his countenance wore an anxious expression. In the evening he was in a state of busy delirium, and symptoms of acute meningitis were conclusively present; at the same time all the articular symptoms disappeared. Enemata were administered, cold to the head, and blisters, without the smallest relief. He was supported carefully with milk, beef-tea, and a fair allowance of wine. His pupils were dilated and almost inactive. He was restless, and continually tossing his arms about. He continued about 48 hours in the above state, and on the morning of the 7th had been without sleep; his pulse was 152, and very weak; his temperature 102°6. He was then ordered draughts containing twenty grains of chloral hydrate, with syrup of ginger; one to be taken immediately, the others at such intervals as might be required. Soon after taking the first draught the muscular twitchings, or tossing about, ceased, and he eventually fell into a quiet sleep. He passed the day and night tranquilly, taking his nourishment at intervals, and on the morning of the 8th was quite rational and comparatively comfortable; but about 2 P.M. there was a return of the unfavourable symptoms (less in degree). He was given half a chloral draught, which quickly composed him, and from that time to the present there has not been any return of head-symptoms. The rheumatic affection relapsed, both knees becoming painful to the touch, and swollen. He steadily improved from his extreme prostration, and was convalescing, but suffered from organic cardiac disease, which must unfit him for further service.

'He had no recollection whatsoever of the *Cambridge*, the ship from which he was sent into hospital, nor of any circumstance immediately preceding his illness. The case is remarkable; first, for its rarity; secondly, from the fact of the disease being almost invariably fatal; and thirdly, for the good effect produced by the administration of the chloral hydrate.'

MATERIA MEDICA AND THERAPEUTICS.

DEXTER ON A NEW TREATMENT OF CHOREA. Dr. Ransom Dexter, of Chicago, writes (*Chicago Journal of Mental and Nervous Diseases*) as follows. In the early part of January, of the past winter, my attention was called to the case of Miss D., aged thirteen, who had been suffering from impaired health for the previous six or eight weeks. This was attributed to hard study at school, and an effort was made to avert any further serious consequences from that cause, but too late, as the result proved; in less than forty-eight hours after her withdrawal from school, she presented decided symptoms of chorea. On January 14 the disease had fairly made its invasion; and the first prescriptions I thought best suited for the existing conditions were as follows: Extract of valerian and cimicifuga, twice a day; and the elixir of pepsin, bismuth, and strychnia, before each meal; and bromide of potassium and cannabis Indica at bed-time.

In a few days I noticed some malarial periodicity, but no cardiac or rheumatic troubles, though my little patient was growing worse rapidly. I now prescribed Fowler's solution of arsenic; but the symptoms appeared obstinate. I then solicited the advice of one of our most competent physicians, who approved of the adjustment of the agents to the peculiarities of the case; but the course of treatment to be instituted for the periodicity was a complicated question. After canvassing the *pros* and *cons*, we decided to try, cautiously of course, small doses of quinine and iron.

I accordingly did as we thought best; but as soon as the slightest effect of quinine was observable, the following symptoms ensued: hemiplegia on the left side; dilatation of the pupils of both eyes; some choreic movements during sleep, increasing so much when awake that the patient had to be held down on the bed or lounge; she could not sit up, but in attempting to do so, would be jerked down, instantly and violently, by the muscular contraction.

But four grains of the quinine had been given when the peculiar symptoms of this complaint became general, and I despaired of saving my patient, apprehending a general failure and wearing out of the vital powers.

Only ten days had now elapsed, and during that time I had reviewed the writings of several of the most able modern writers on the subject, and was unable to see wherein I could improve upon my first system of treatment. This stage of the disease, with its outlook, was unpromising.

Not being satisfied with either the pathology or the therapeutics of the disease in question, I began to review the facts and phenomena, and the following queries suggested themselves to my mind. 1. Why are choreic patients quiet during sleep? 2. Why do noise and excitement aggravate the condition? 3. Why are the symptoms aggravated by the entrance of neighbours or strangers? 4. Why was the condition so unfavourably affected when the piano was played? 5. Why did so small an amount of quinine have such an injurious effect? 6. Finally, what are the unquestionable physiological interpretations of the phenomena under all these conditions and circumstances?

To me, the whole problem seemed solved in an

instant, as follows. 1. All the sensorial ganglia, or the centres for the nerves of the separate senses, were more or less affected; and the sensori-motor centres were the special seat of the disease. 2. The pathological condition could not be other than an asthenic irritation of the sensori-motor organs. 3. These organs, and especially the sensori-motor guiding ones, must have physiological and therapeutical rest, with the additional treatment by such medicinal agents as will also contribute to that end. 4. If the physiological and therapeutical rest be the *sine qua non* of treatment, then what is to be done?

At first, I essayed to carry out these ideas by blindfolding my patient, filling the ears with cotton, excluding all company, and keeping her in one room, where everything was familiar. The blindfolding, and cotton in her ears she could not tolerate, from her sensitive condition. I then ordered the blinds closed, kept her in a middle room of the house, and enjoined the most strict quietude in every particular, even to lying as perfectly still as possible upon a lounge, that the nerves of touch might not be wrought upon; also in every other particular pertaining to the five senses, and muscular motions.

I continued the extract of valerian, cannabis Indica, and bromide of potassium, with an occasional cathartic to act as a revulsive. Her attendant was her mother, most of the time, but relieved by the patient's father. But little was said in the room; the patient could not speak; and the parents spoke as little as possible, the room being kept in a twilight condition.

In eight hours after this treatment was instituted, we were impressed that a noticeable improvement had ensued; but, within twenty-four hours thereafter, the improvement was a decided one. From that time the improvement continued rapidly; and in six days all choreic movements had subsided.

I do not believe the patient's general health suffered from want of light, but on the contrary, was much better without it, as long as she suffered from chorea.

It would be difficult to make me believe that this rapid recovery was a mere coincidence; therefore, I feel at liberty to express my views, and ask the profession to try them, or be governed by the principle that the *sensorial centres in chorea need physiological and therapeutical rest*.

COLLAS ON IODISED ALBUMEN. — M. Collas (*Bulletin Général de Thérapeutique*) describes a new process for the administration of iodine. Alcoholic solution has been found too irritant in many cases, and as the iodine acts on the alcohol, forming a hydriodic ether, it follows that the tincture is liable to vary in its composition. Iodide of starch has been recommended, because the association of iodine with some organic substance has been found the most certain method of administration. But this preparation is of variable strength, and has besides an unpleasant taste. Iodised albumen, however (M. Collas considers), obviates all these inconveniences, and can, without much difficulty, be formed into pills.

The albumen is prepared by agitating actively an albuminous solution with iodine in very fine powder, or in solution in some appropriate vehicle. The mixture is at first highly coloured, blackish-brown, but this colour gradually disappears in several hours of contact, and the preparation no longer strikes the violet

colour with starch. The product is then desiccated under gentle heat in an air-bath, when it may be made in pilular mass. The dose is so arranged that each pill should contain five milligrammes of iodine.

The experiments at the Hospital Beaujon by M. Dolbeau have shown that iodine thus prepared has no bad effects whatever. The pills in the dose of five or six per day acted rapidly in the resolution of an hypertrophy of the thyroid gland. Iodised albumen seems to have the efficacy of cod-liver oil. It has been administered in cases of chronic osteitis, ganglionic engorgement, strumous keratitis, and in two cases of Pott's disease with congestive abscesses. It may be continued for several weeks without stomach trouble or other inconvenience.

BRUNTON ON THE TREATMENT OF HEADACHE.—Dr. Lauder Brunton, in a paper 'On the Action of Purgative Medicines,' recently published in the *Practitioner*, writes: 'The administration of a brisk purgative, or small doses of Epsom salts, thrice a day, is a most effectual remedy for frontal headache when combined with constipation; but if the bowels be regular, the morbid processes on which it depends seem to be checked, and the headache removed even more effectually, by nitro-hydrochloric acid or by alkalies, given before meals. If the headache be immediately above the eyebrows, the acid is best; but if it be a little higher up, just where the hair begins, the alkalies appear to me to be more effectual. At the same time that the headache is removed, the feelings of sleepiness and weariness, which frequently lead the patients to complain that they rise up more tired than they lay down, generally disappear.'

DECLAT ON THE USE OF AMMONIA IN CHOLERA. Ammonia and the chief salts have an antifermentative action in germ-maladies. But of all combinations or forms of ammonia that of ammoniacal gas and of phenic acid is the best suited to combat confirmed cholera, especially if used in subcutaneous injections (half per cent.) of 100 drops each, by the dose of 2 to 2½ per cent., or in intravenous injections.

PAGET HIGGS, D.Sc.

TOMMASI ON THE ACTION OF BROMIDE OF POTASSIUM.—In a note on an article by Professor Binz, of Bonn, on the therapeutic use of bromide of potassium, in which the potassium is regarded as the true depressor of the muscular and nervous systems, and the bromine as inert, Professor Tommasi makes the following remarks (*Il Morgagni*, January 1, 1874, and *Giornale della reale Accademia di Medicina di Torino*, June 10). 'After many experiments in the use of the bromide of potassium, I believe I may express its action as follows. It has a positive action (1) in acute delirium, febrile or non-febrile; (2) in the eclamptic, epileptic, and epileptoid states; (3) in headache, but in a much less degree.

'On the other hand, I have found it completely useless in cases of insanity (*alienazioni mentali*); in the peripheric forms of nervous disease; in spinal irritation; in angina pectoris; and in asthma.

'It certainly has some hypnotic action, but does not approach chloral. In acute delirium I have given as much as eight grammes (two drachms) daily, and in epilepsy twelve grammes (three drachms), always with advantage, in the sense of diminishing the violence of the paroxysms. I know one case of epilepsy which may perhaps be said to be cured. On the other hand, I have given the bromide in large

doses in cases of alternating convulsions without observing any effect to be produced.

'I have often used it in spermatorrhœa and priapism and in the irritative stage of spinal disease.

'I place but little credit in Binz's opinion, that all the effects are to be attributed to the potassium; I believe that in the cases referred to the medicine did good as bromide.'

A. HENRY, M.D.

BROWNE ON AN IMPROVED INHALER.—Mr. Lennox Browne suggests (in the *Medical Times and Gazette*, June, 1874), an improved inhaler, which is manufactured by Messrs. Corbyn. Starting from Maw's double-valve inhaler, the lateral tube has been carried down deeper into the body of the inhaler, so that the admitted air is made to ascend through a longer column of water, and is consequently fully impregnated with the medicament before reaching the mouth. The lateral tube admits a thermometer, which carries a water-mark. An India-rubber nasal-piece is added for nasal inhalation. Where it is desirable to maintain a high temperature, the inhaler should remain in the box while being used. The price, complete in box, is 10s. 6d.

CULLINGWORTH ON THE TREATMENT OF SYPHILIS BY SUBCUTANEOUS INJECTION OF MERCURY.—Mr. C. J. Cullingworth reports (*Lancet*, May 23, 1874), as follows on this method of treating syphilis. The solution for injection has the formula: Hydrag. bicyanidi, 12 gr.; glycerini puri, 3iv.; aquæ dest. ad 3iv.; and the medium dose is ten drops (containing one-sixteenth of a grain), to be injected into the outer aspect of the upper arm, or better still between the spine and the lower angle of the shoulder-blade, every morning, or as often as required. Twenty patients were injected with this and the following solutions.

1. Three grains of corrosive sublimate, in an ounce of water.

2. Dr. Staub's solution, containing, bichloride of mercury, 1·25 grammes; chloride of ammonium, 1·25 grammes; chloride of sodium, 4·15 grammes; the white of an egg; distilled water, 250 grammes. This was objected to, as in the course of a day or two there was a considerable deposit, and because its preparation was rendered troublesome by the repeated filtration required.

3. A solution containing the double iodide of mercury and sodium.

Preference was given to the first formula, containing the cyanide of mercury, as it caused less pain, and less thickening of the part injected. It has also the following advantages:—

1. Certainty and rapidity with which the symptoms disappear; 2. The small quantity of mercury necessary; 3. Exactness in the measurement of the dose; 4. Impossibility of disappointment through patients neglecting to take their medicine; 5. Absence of gastric and intestinal irritation; 6. Economy in hospital use; 7. The avoidance of publicity involved in using baths; 8. The means it affords of rapidly affecting the system in certain grave complications.

BLANC ON THE TREATMENT OF PHTHISIS BY PHOSPHATE OF LIME AND THE JUICE OF RAW MEAT.—Dr. Henry Blanc reports (*Lancet*, June 13, 1874) as follows on the various preparations of phosphate of lime, and on the method of giving raw meat to phthical patients. The syrup of the lacto-phosphate of lime (Dr. DUSART's) is well tolerated at first, but after a while induces dyspepsia, nausea, and somnolence.

M. Coirre's solution of chlorhydro-phosphate is not grateful to the patients, but is well tolerated by those who are able to overcome their dislike to the rough acid taste of the drug, and has given good results. Another muriatic preparation, the wine and syrup of Chennevière, specially the wine of chlorhydro-phosphate of lime, is a very useful remedy, being both pleasing and well tolerated by the patient. The monocalcic phosphate syrup of M. Barbarin has not been yet sufficiently tested to enable Dr. Blanc to record an opinion about it. When the patients have not been able to persist in the use of the above-mentioned preparations of phosphate of lime, Dr. Blane has prescribed a drachm to a drachm and a half daily of the syrup of triple phosphates (Easton's formula), giving at the same time a couple of grains of phosphate of lime at the principal meals. The cases that are progressing most favourably are those who take the muriatic solutions—Coirre's solution or Chennevière's wine, and at the same time a drachm daily of the syrup of triple phosphates. Under whatever form the phosphate of lime may be prescribed, it should always be taken at meals.

Dr. Blanc administers the raw meat in the following manner. A pound or a pound-and-a-half of fresh beef, deprived of fat, bones, &c., is placed over a quick fire for a few minutes, in order to whiten and harden the external surface only; the piece of meat is then cut into two or three pieces corresponding to the size of the meat-press, and all the juice is extracted by the pressure of a powerful screw. The superficial coction is necessary to overcome the elasticity of the meat, which renders the extraction of the juice a very difficult matter unless more powerful machines be used than the simple one at present required. A pound-and-a-half of good fresh meat gives a teacupful of juice. The juice should be prepared daily. The juice should be mixed with equal parts of tepid broth, made in the bones, and flavoured with salt and pepper, and to which tapioca, vermicelli, &c., can be added. Care should be taken that the broth is never more than tepid, otherwise coagulation takes place. Half the broth should be given at lunch, and the remainder at late dinner; and during both meals some preparation of phosphate of lime should also be taken.

H. SUTHERLAND, M.D.

OTOLOGY.

VOLTOLINI ON ARTIFICIAL PERFORATION OF THE MEMBRANA TYMPANI.—In the *Monatsschriften für Ohrenheilkunde* for January, March, and May, R. Voltolini describes a method of accomplishing the long sought for desideratum of keeping open an artificial perforation in the membrana tympani. Having made a perforation on each side of the manubrium by means of the galvano-caustic or the knife, he inserts, by the aid of a pincette which he has had constructed for the purpose, a tube of gold shaped like a ring, but not joined at the ends of the canal, and having at the part opposite the split an opening on one side of the canal. The split in the ring is passed into the cavity of the tympanum, an end passing on each side of the manubrium, and when in position the ends are pressed together, so as to make the division less than the manubrium, and so prevent the ring from falling out. Placed in this posi-

tion, the orifice in the other side of the ring is towards the meatus auditorius externus. The ring canals are made of fine gold, are of different sizes, from 4 to 2½ millimètres in diameter, and have a canal lumen of one millimètre. The openings in the membrana tympani ought to be made at the end of the first third of the manubrium, commencing at the processus brevis, so as to give the ring as little chance as possible of falling out should suppuration supervene and lengthen the incisions to below the end of the manubrium; and as a preventive, in the same event, of the ring falling into the tympanic cavity, he keeps a thread attached to it till all signs of suppuration are passed. In many cases the operation is easy; in others difficult, on account of the oblique position of the membrana tympani, or narrowness of the meatus auditorius externus; and in some impossible, on account of exostosis, etc.

BONNAFONT ON THE PERFORATION OF THE TYMPANIC MEMBRANE.—M. Bonnafont, in a communication reported in *La France Médicale*, describes two instruments for perforating the tympanic membrane, one by M. Aubrey, and the other by M. Mathieu, both instruments being constructed so as to leave eyelets in the membrane. He says the operation scarcely lasts two seconds; and, during the operation, he ensures steadiness on the part of the patient by causing insensibility of the membrane by injecting ether-spray against it from Richardson's apparatus for about a minute and a half. In answer to Mr. Gosselin, M. Bonnafont said the cases demanding the operation were idiopathic thickening where there was inertia of the membrane, or resulting from paralysis of the muscles of the ossicles, the operator always previously assuring himself, by the usual means, of the integrity of the acoustic organ itself. He believes that the results to be obtained from this operation in proper cases may be compared to those obtained for the eye by the operation for cataract.

W. LAIDLAW PURVES, M.D.

TOXICOLOGY.

MALMSTEN ON CHRONIC ARSENICAL POISONING. Malmsten (*Hygiea*, 1873, and *Nordiskt Medicinskt Archiv*, 1874) relates that a labourer, aged twenty-six, had suffered three years ago from inflammation of the lungs, which confined him to bed for a long time. When he was able to get up, his feet would not support him, but gave way beneath him. Sensation was diminished in the feet and legs; he had trembling of the fingers, and occasional creeping sensations in the hands and feet. He could not support or lift any rather heavy object without letting it fall. After remaining five weeks at home, and thirteen in a hospital, sensation was entirely lost in the soles of the feet and greatly diminished in the hands. The organs of sense were normal. He improved a little under the use of baths and electricity, and after a course of cold-water treatment became quite sound. In January, 1873, after exposure to cold, he had an attack of vomiting for three or four days; he recovered from this, but three weeks afterwards had a similar attack, which lasted six days. After his recovery, he had numbness in the hands, especially in the tops of the fingers, and also in the feet, where cutting pains were sometimes felt. There was a certain amount of stiffness of the ankle and

knee joints, with difficulty in walking. He had never had syphilis, and had lived in good hygienic condition.

On March 14, 1873, he was admitted into the Seraphim Hospital. His muscular structure was lax, his gait unsteady; his hands, feet, fingers, and toes could be moved without impediment. Sensation was somewhat diminished in the soles of the feet and in the palms of the hands, and electromuscular contractility remarkably so; in the legs and forearms it was less so. He had occasional creeping sensations in the hands and feet. The strength of his hands was diminished. The intellect was unimpaired; the organs of sense were normal. His condition improved under the use of iodide of potassium and galvanism, and on May 10 he was discharged cured.

Arsenical poisoning was suspected, and after repeated questioning he acknowledged that he had taken 'merkulja' (a country name for arsenic), when he felt himself indisposed, after which his illness appeared. He had obtained the arsenic from another lad to give to horses. A. HENRY, M.D.

PSYCHOLOGY.

LUNIER ON THE PSYCHICAL EFFECTS OF POLITICAL AND SOCIAL TROUBLES.—In a series of articles in the *Annales Médico-Psychologiques* (May, 1874, and preceding numbers), Dr. L. Lunier examines the effect produced by the political and social troubles of France in 1870-71 as regards mental disorders, and the following is a *résumé* of the conclusions arrived at. The events of these years produced between July 1, 1870, and Dec. 31, 1871, between seventeen and eighteen hundred cases of insanity. During this period, however, there were admitted into the French asylums, 1,300 patients fewer than in the corresponding period of 1869-1870, so that the war caused as its immediate result a considerable diminution in the number of admissions, and in the total number of those in asylums at the end of the year. This diminution was due partly to the derangement of the asylum administration, partly to the parsimony of some of the departments, and also to the suspension of certain etiological influences which, at ordinary times, produce mental disorder; also the acute character of the insanity in 1870-71, and the rapid termination either in death or recovery, tended in a measure to diminish the number of those remaining at the conclusion of the period. From the end of the year 1871, however, the number of admissions gradually rose, and in 1872 showed an increase which was quite exceptional, viz. 2,785, while in 1873 the increase has not been more than 872, a number more nearly approaching the usual average. The mental disorders due to the events of the war-period were more frequent amongst men than women. In the subsequent period the increase has been chiefly amongst females, but the difference in either case was not great. Hereditary predisposition played an unimportant part in the insanity caused by the political events, being observed in only twenty-four per cent. of cases, while at other times it is found in sixty-three per cent. In estimating the causes of this insanity, it is found that some acted indirectly by exciting profound emotion; others operated directly on the individual, e.g. in departments occupied or menaced

by the enemy. The causes most frequently observed were fear at the approach of the enemy, dismay at the prospect of enforced service, the departure of some dear relative for the seat of war, the moral and physical exhaustion produced by the war, and especially the siege of Paris, the news of disasters, and the occupation of the country by the Germans. Although the causes were altogether of a depressing character, every form and variety of mental disorder were met with. The expansive varieties were more frequently seen than the depressed. It was clearly demonstrated that the same cause might produce totally different forms of insanity, and that from causes completely dissimilar there might proceed sometimes the same, sometimes different kinds of mental disorder. In some cases, especially where there had been alcoholic intemperance, certain symptoms indicated to a certain extent the cause which had given rise to them. Among the morbid phenomena most frequently noticed were stupor, pantophobic terror, refusal of food, suicidal propensities, exalted mania, hallucinations of hearing, and delusions of persecution.

G. FIELDING BLANDFORD, M.D.

REVIEW.

A Treatise on Food and Dietetics, Physiologically and Therapeutically considered. By F. W. PAVY, M.D., F.R.S., Fellow of the Royal College of Physicians; Physician to, and Lecturer on Physiology at Guy's Hospital. London: J. & A. Churchill. 1874. Pp. 559.

In this work Dr. Pavy has collected, and, with few exceptions, has usefully and intelligently digested the information which we possess in reference to the food of man.

Having pointed out, in a preliminary chapter, the relations of food to the work performed by the animal body, and drawn attention to the function of vegetables in forming the compounds which serve as the organic nutriment of the animal, the author treats of the classification, chemical relations, digestion, assimilation, and physiological uses of the various alimentary principles. He then discusses in detail the alimentary substances, which he arranges under the heads of animal alimentary substances, vegetable alimentary substances, beverages, and condiments. Separate chapters deal with the Principles of Dietetics, Practical Dietetics, and Therapeutic Dietetics. The work affords ample evidence that the author has carefully, and at great pains, made himself a master of that part of the literature of his subject which is accessible to the English and French reader, although it appears to us that in some cases he exhibits a deficient acquaintance with the more recent German literature.

Dr. Pavy's book commences with some observations on 'Matter and Force.' 'Around us,' remarks the author, 'we have to deal with matter and force—the one a substantive entity, the other appreciable only as a principle of action. It has long been known that (as cognisable in our own era) matter can be neither created nor destroyed. It may be variously combined and modified, but it remains the same in essence and unaltered in amount. Force, also, has more recently been recognised as similarly conditioned; and, in order that the bearings of food

in relation to this principle may be understood, some preliminary considerations explanatory of the views now entertained regarding it are necessary.' Then follows a slight sketch of the historical development of the doctrine of the Correlation of the Physical Forces, which commences with a notice of the researches of Grove, and deals with those of Meyer and Joule, which culminated in the discovery of the mechanical equivalent of heat, and the establishment of the doctrine of the conservation of force. Those who refer to the development of the idea of the correlation of the physical forces, unwillingly commit a great injustice to the man who, long ago, established by direct experiment the conversion of mechanical work into heat, and who further established the connection which exists between the work done by an animal and the food with which it is fed.

It was at the very close of the last century that Benjamin, Count Rumford, by his famous experiments on the heat developed during the boring of cannon, dealt a fatal blow to the old material doctrine of caloric, and pointed out in a conclusive manner, although not so as to admit of quantitative determination, the connection between heat and motion. ('An Inquiry concerning the Source of Heat which is generated by Friction.'—*Philosophical Transactions for 1798*, and *Nicholson's Journal*, 1799, p. 106). He devised apparatus by which he demonstrated that in the boring of a cannon an amount of heat is generated sufficient to raise a large quantity of water to the boiling point; he weighed the chips of metal separated during the operation, and determined their specific heat, which he showed was exactly the same as that of the cannon from which they had been detached. Further, Rumford speculated with perfect correctness that the heat developed during the boring of the cannon was the result of the work done by the horse which was made to turn the boring machine, and was derived from the food which the horse had consumed. We cannot but allude to these researches of Count Rumford, as they appear to us to deserve the first place in any historical sketch, however short, of the development of the doctrine of the correlation of the physical forces.

In his attempt to define the terms force and energy, Dr. Pavy has expressed himself in such a manner as to lead us to believe that considerable confusion exists in his own mind in reference to the real meaning of the words. 'It is necessary,' says the author, 'to state here that the term force, when used in a strict sense, is employed under a more limited acceptance now than formerly. Originally it represented what is now distinguished as both "force and energy." By force, in a rigid signification, is understood the power of producing energy, by "energy" the power of producing work. To give an illustration: powder has force, the cannon-ball energy; but to speak of the force of the cannon-ball is incorrect.

'I may also remark that the words actual and potential are in frequent use to qualify the state in which the energy is met with. By actual energy is meant energy in an active state—energy which is doing work. By potential energy, energy at rest—energy capable of doing work, but not doing it, etc.' After reading attentively the passage which we have quoted, we have come to the conclusion that Dr. Pavy believes the term force, as now used, to be a synonym for potential energy. 'Powder has force,' says the

author, 'the cannon-ball energy; but to speak of the force of the cannon-ball is incorrect.' Now the truth is, that the term force is a much more comprehensive one than that of energy, as Dr. Pavy might have concluded had he reflected that we still speak, and with perfect correctness, of the 'force of gravitation,' of the 'force of cohesion,' &c.

Force has been very aptly defined (Tait and Thomson) as 'any cause which tends to alter a body's natural state of rest, or of uniform motion in a straight line.' Energy, on the other hand, is easily defined as the capacity for doing work, and bodies possess it in virtue of their position (potential energy) or in virtue of their motion (kinetic energy). The gunpowder referred to by Dr. Pavy possesses potential energy—not force in our strictly accurate modern phraseology; on the other hand, the cannon-ball in motion possesses kinetic energy, and we shall not be violating our definition of force, if (in relation to other bodies with which it may come into contact) we do speak of the force of the cannon-ball.

These remarks are made in no hypercritical spirit, but merely because we consider that, in dealing with matters which admit a perfectly exact treatment, and which form the basis of the theory of food, too much care cannot be taken by any writer on dietetics.

The first part of the chapter on The Nitrogenous Alimentary Principles strikes us as peculiarly unsatisfactory, for the author's description of the albuminous or proteine compounds of animal or vegetable origin might have been written twenty years ago. Albumen, fibrine, and caseine, vitelline, globuline, and syntonine are the animal albuminous substances described. Vitelline is described as the modified form of albumen which exists in the yolk of the egg. Syntonine is referred to as muscle-fibrine! The vegetable albuminous substances are, according to the author, vegetable albumen, vegetable fibrine (a compound of vegetable gluten and caseine) and a vegetable caseine. We cannot help regretting that Dr. Pavy has not made himself acquainted with the really splendid researches of Professor Ritthausen (*Die Eiweisskörper der Getreidearten, Hülsenfrüchte und Oelsamen*, Bonn, 1872). Ritthausen's researches establish the existence of the following albuminous substances:—1. Vegetable albumen proper: 2. Substances belonging to the group of vegetable caseines, viz., *a*. legumin; *b*. gluten-casein; and *c*. conglutin: 3. Substances which may be classed as vegetable gelatins, viz., *a*. gliadin; *b*. mucedin; and *c*. gluten-fibrin. Ritthausen's researches have not hitherto been fully laid before the English scientific public, and we hope that in a future edition of his work Dr. Pavy will not fail to do so.

If we except an apparent want of acquaintance with the researches of the last few years (seeing that the names of Brücke, Schiff, Kühne, and Thiry, do not find a place beside those of Mialhe and Corvisart in Dr. Pavy's book), the remainder of the chapter on the nitrogenous principles is very satisfactorily treated. The relation of nitrogenous food to muscular work is ably and exhaustively discussed; a capital *résumé* of Dr. Parkes's admirable research being given. The same judgment must be pronounced in reference to the discussion on the part served by the carbohydrates—their conversion into fats, the dietetic value of alcohol, &c.

In spite of the criticisms which we have felt compelled to make, we can confidently affirm that Dr. Pavy's book is one which constitutes a valuable ad-

dition to the medical library. It contains more information on the subjects of which it treats than any similar English book, and it is certain to prove exceedingly useful to the medical practitioner.

ARTHUR GAMGEE, M.D., Manchester.

MISCELLANY.

TRICHINA SPIRALIS.—In the *post mortem* examination of a man 73 years of age, Professor Klob, of Vienna, lately found all the muscles of the body studded with thousands of trichinae, mostly calcified, but some still alive. The man had died of marasmus. He had not left Vienna for ten years; but had previously spent some time in Germany. Dr. Klob believed that the invasion of trichinae must have occurred at least fifteen or twenty years ago.

THE PLAGUE.—According to a recent telegraphic despatch, the plague has broken out at Bagdad and Tripoli. During last month a commission composed of four physicians was sent by the Ottoman Government to hold an inquiry respecting this disease, and report on it. It has appeared at Hillé Divanieh, Dagara, and Afidj. Quarantine regulations have been promptly applied all round the infected districts; and the last telegrams from Bagdad, up to the 14th instant, announce that the epidemic has considerably diminished. It has also been reported that the plague has broken out at Sena, in Persian Kurdistan, where it made its appearance in 1871; but this news requires confirmation. The plague has shown itself in another quarter, at Merdj, a city in the district of Bana, at a distance of twenty hours from Bengazi, a port of South Africa. The most rigorous sanitary precautions have been ordered and carried into execution at the Italian sea-ports, with regard to all vessels coming from the countries suspected of being plague-stricken. Doubtless similar precautions will be adopted in the French sea-ports, especially that of Marseilles.

ABSENCE OF OXYGEN IN THE WATER OF ARTESIAN WELLS.—M. Gérardin, in a paper read to the Paris Academy of Sciences descriptive of the artesian wells of Grenelle, finds there is no oxygen present in the water from the lower sandstone of this locality, nor from the Rilly gravel beneath the clay, and at contact with the chalk (the water was obtained out of contact with air from various depths by means of a syphon invented by the author), nor from the Soissonais gravel. Neither was this gas discovered in the water from the artesian well at Gonesse. M. Gérardin concludes that water obtained from subterranean depths does not contain oxygen if kept from contact with the atmosphere. This precaution is essential, for in contact with air it dissolves several cubic centimètres of oxygen. The author has often found in the interior of the ascension tubes long white opaline filamentary algæ. These algæ present the curious property that they remain white in solar light as long as the water is deprived of oxygen; but they become green the instant the water is the least aerated. Their sensibility to the action of oxygen is the most delicate. The action of the algæ serves to confirm the chemical test with hyposulphite of soda.

ARSENICAL POISONING BY WALL-PAPERS.—Dr. George Johnson, in an extremely able lecture published in the *Sanitary Record* of July 4th and 7th, collects some well-marked cases of arsenical poisoning, due to the wall-papers of rooms, his first three cases being in the persons of well-known physicians, whose sufferings were considerable, as the cause of them was unequivocal. Some of these cases are described in detail. The author goes on to show that the symptoms which are believed to have resulted from the use of arsenical wall-papers are similar to those which occur more or less constantly and severely amongst work-

people who are engaged in the manufacture of arsenical pigments, or of the papers, artificial flowers and leaves, and other articles which are coloured with arsenical compounds. Dr. Johnson then proceeds to reply to the arguments of those who doubt the injurious effects of arsenical wall-papers, and who maintain that, if these papers were really injurious to health, their very general use for many years past would have caused numerous, and not rare and isolated cases of illness. To this objection Dr. Johnson replies by saying that probably many more cases of illness have resulted from the use of these papers than are known or even suspected to have had this origin. Then the quantity of poisonous dust thrown off from an overcharged arsenical paper is so small, that those only who are more than ordinarily susceptible suffer appreciably from the inhalation of the poison. In illustration of this, various examples of idiosyncrasy are referred to. A comparison is made between the symptoms caused by the inhalation of arsenical dust and those of 'summer asthma, or hay-fever.' Happily there are few individuals so sensitive as to have their eyes and nose and throat excited to inflammation by a neighbouring grass-field. Amongst workmen whose occupation compels them to breathe an atmosphere largely charged with arsenical dust, there are but few who do not suffer more or less seriously from the poison; but the comparatively small amount of poisonous dust which ordinarily floats in the air of a room hung with an arsenical paper has no appreciable effect on any but those who are peculiarly sensitive to the influence of the poison, a sensitiveness which may sometimes be shared by several members of the same family. The comparative rarity of these cases affords no reason for doubting their reality when they do occur, or the intimate relation between the symptoms and the inhalation of arsenical dust. The extreme tolerance of noxious influences displayed by some individuals is as remarkable and inexplicable as the high degree of sensitiveness manifested by others. Undoubted cases of poisoning by arsenical papers are common enough, and sufficiently serious to call for an energetic protest against the continued use of such papers; and it should be borne in mind that arsenic is often present, not only in bright green papers, but in pale green, grey, and even brown papers.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JULY 22, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

GOODELL ON DISEASES OF WOMEN.*

(Concluded from page 431.)

Abdominal Supporters.—They may not cure, but in certain conditions of distended abdominal walls they most certainly alleviate the urgent symptoms, especially in those cases where the patient herself instinctively supports her abdomen with her hands from a sense of downward pressure. Nothing has the writer seen to relieve a bed-ridden hysterical woman more than this simple procedure.

The 'rationale' is that the weight of the abdominal viscera is not borne by the pelvic organs, but from the curvature of the spine the downward pressure is spent upon the pubic bones. The generative organs are shielded below the promontory of the sacrum, and the pressure to which they are subjected is an oblique one. A displaced or a flexed uterus may give rise to discomfort if it become congested or inflamed, and it becomes intolerant of the superincumbent weight, however slight. If the abdominal wall be pressed backwards and upwards towards the sacral promontory, a shelf is formed for the viscera to rest upon; and further, by shortening of the conjugate diameter of the superior strait, the space for reception of the viscera is lessened, and to that extent the generative organs are protected from sudden succussions.

The curves of the spine of the woman may become altered either from the effects of time or from the defects of carriage, so that the double curve may be lost and become bow-like instead. This change produces an alteration in the obliquity of the pelvis, the axis of the inlet tending to coincide with that of the trunk, so that the pressure of the abdominal viscera is direct in its action on the pelvic organs. The cure is in bringing back the sigmoid curve of the spine, which a brace for the shoulders and an abdominal support for the belly does and can effect.

Prolapsus of the Womb.—This is divided into three varieties; prolapse of the womb proper; prolapse of the cervix (from hypertrophic elongation); prolapse of the cervix from elongation of the supravaginal portion (by traction). In the first condition all falls down, and there is little or no increase in the length of the uterine cavity. In the latter two there may be a slight sinking of the fundus; but for the lengthening of the cervix there is a great increase in the measurement.

The first condition in old women arises from loss of the fat pads and the double curve of the spine;

in young women from subinvolution, congestions, long-continued vomitings, tight-lacing, skirts unsupported by braces, lacerations of the perinæum, and last, but not least, the prolonged use of the obstetric binder. Its treatment is relief of the congested uterus when it exists, pessaries to support the fundus, and braces and belts to restore the curvature of the spine where it has been lost.

The second variety arises from nutritive activity of the cervix, which may be the result of cervical metritis, from the contusions of labour which produce the hypertrophic elongation of the cervix as a whole, or of only to a portion, usually the anterior, forming what is called 'tapiroid,' from its likeness to the snout of the tapir. Wherever the vaginal portion is so long as to protrude from the vulva, it is congenital, or the exaggeration of a congenital condition. One of its modifications is the conical cervix. The treatment of these several conditions is to amputate with the scissors or *écraseur* when the prolapsed part is unduly large and inconvenient to the patient. The conical cervix rarely needs shortening; slow dilatation by sponge-tents just before the catamenial flux, and rapid distension afterwards by the dilator, will generally effect its cure.

The third variety, cervical elongation (by traction) of its supravaginal portion is entirely a different condition. It is a hernia of the bladder and vagina, acting mechanically on a tensile womb. The lower portion of the corpus participates in this elongation, because the muscular structure is less developed than that of the upper; but the elongation is greatest at and about the internal os, through the absence of muscular structure—the resistance there is least. The eversion of the os and circular hypertrophy of its lips arises from impediment to the circulation in the vaginal portion. The only treatment is to keep the woman in bed for a short time, so as to relieve the hypostatic congestion, and then remove the vaginal portion of the cervix by the wire-*écraseur* or the galvano-caustic loop. The supuration from the open wound sets up nutritive changes so as permanently to contract and consolidate the elongated portion. Great care should be taken not to wound the bladder or the peritoneum in Douglas's pouch. Where the fundus is prolapsed also, the vulvo-vaginal opening must be contracted. A horse-shoe shaped strip of mucous membrane an inch wide should be pared off from a little below the level of the meatus urinarius, and brought together by wire-sutures.

Fibroid Tumours.—The object to be obtained is to stay the hæmorrhage, to check their growth, to allay the pain, and lessen the weight and inconveniences. To stay the hæmorrhage teaspoonful doses of the liquid extract of ergot every two or three hours or twenty to thirty grains of gallic acid, have often proved the most efficient remedies with the author. The infusion of *vinca major* he has not tried, but has seen cinnamon boiled in milk act like a charm when all else had failed. Leeching or scarifying the cervix a day or two before the menstrual epoch does tend to lessen the bleeding materially. If the hæmorrhage yield to none of the ordinary measures, the cervix itself should be plugged by means of a large sponge-tent. This not only arrests the bleeding at the time, but diminishes the tendency at future periods. Should, on the removal of the tent, the bleeding still continue, stretch open the cervix with the dilator, inject into the uterine cavity between the blades two drachms of

* Reprint of articles published during January and February, 1874, in the *Philadelphia Medical and Surgical Reporter*.

the tincture of iodine or a strong solution of Monsel's salt, or push up a piece of lunar caustic, about 5 to 10 grains in weight, and let it dissolve, or swab out the uterus with fuming nitric acid, taking care to wash it out well afterwards with water. If these measures do not succeed, incise the whole length of the canal bilaterally with the hysterotome, or at several points with the probe-pointed curved bistoury. If the cervix be long, the author expands it rapidly with his dilator and then stuffs it with laminaria tents.

Intercourse he forbids as conducive to their growth. Hildebrandt's method of hypodermic injection of ergot is recommended, as numerous good results have been seen to follow its adoption. Ergotism may be produced, evidenced by severe uterine pains and a spurious hectic fever and headaches; it, however, soon passes off if the injection be omitted for a time. The writer advises ten to fifteen grains of the officinal fluid extract, diluted with enough water to fill the hypodermic syringe, to be used every night until symptoms of uterine contractions are established.

Cancer of the Cervix Uteri.—Immediate removal by the galvano-caustic loop of any malignant or quasi-malignant growth is enforced, and if any portion remain it should be dug out by a red-hot spatula. Should there be a tendency to closure of the cervical canal, the occasional use of the dilator is of service. If necessary, this operation must be repeated over and over again. Iron, arsenic, and ergot should be given; iron to build up the system, arsenic to repress the tendency to reproduction and systemic poisoning; the ergot to starve out these growths by shortening their rations of blood-pabulum. To correct the offensive odour the writer prefers hydrate of chloral, either as a wash or a suppository, as it relieves the pain at the same time.

Polypus Uteri.—This should never be removed, or at least the first part of the operation in a large tumour be proceeded with, under an anæsthetic; as there is a danger of either cutting the cervix or even the uterus when inverted, should the patient be unconscious. Such would not be the case if conscious, as pain would immediately indicate the condition. The recurrent fibroid is apt to deceive the physician, and induce him to give a wrong prognosis. It should be recognised by its bleeding very freely, emitting a bad odour, and feeling not unlike placental tissue; its structure is so feeble that it breaks down under the least traction. A polypus should be always removed at once if discovered during gestation or labour, or after delivery in the uterine cavity; as, from injuries sustained during parturition, it is liable to become gangrenous, and to kill the woman by absorption of septic matter.

Puerperal Convalescence.—A full and generous diet is advocated for the first day after delivery, and the usual purge on the third to be dispensed with as tending to promote the absorption of septic matter. A recumbent posture is not to be too rigidly enforced, as being liable to weaken and debilitate; and the author argues that, since labour is a natural process, there is no reason why a woman should not sit up or slip into a chair whenever she feels disposed, as such movement induces uterine contraction and helps to get rid of retained clots and offensive discharges. It also helps to equalise the circulation and remove that passive congestion of the uterus, engorgement of the placental site, and that blood-stasis which decubitus favours, which is believed to be a very common cause of posterior displacements.

The binder should not be used longer than forty-

eight hours, as its longer application produces the very evil which it is meant to obviate—injury to the female contour—by weakening the muscles of the abdominal wall. It also acts injuriously, not only by forcing the viscera upon the womb and the womb into the pelvic cavity, but also the pressure of so hard a body on the vena cava impedes the circulation and impairs the process of involution. Should the lochia continue beyond the third week, it may be safely inferred that the uterus is not involuted, or that some unhealed laceration of the cervix remains. Astringent injections are recommended, and large doses of quinine, as the latter acts upon the uterine fibres. If a woman have previously suffered from some uterine affection, she should be, immediately after delivery, placed on ergot and quinine.

Lacerations of the Perinæum.—When the perinæum is torn, air, the author thinks, gains access to the womb, irritating and congesting it, which ultimately prolapses from acquired hypertrophy. Believing this to be the case, every care should be taken to preserve its integrity. The perinæum is directed to be held by inserting one or two fingers in the rectum, and pulling the perinæum towards the pubes, placing the thumb on the child's head, great care being taken not to wound the fourchette. The advantages are that it helps to dilate the perinæum at the same time that there is no direct pressure made on that body, which in its benumbed and stretched condition is only rendered more insensible by the support of the hand. The muscular fibres are brought together and the tension removed off the raphe. The dilatation of the sphincter and forces the occiput against the pubes, and favours extension of the head, especially if the fingers press on the foetal face or chin. Support thus given prevents injury through sudden expulsive efforts. The thumb helps to regulate the passage of the child's head, whereas the hand, by its pressure on the perinæum tends to excite reflex expulsive action. Lastly, the double pressure of the supporting hand and the advancing head on the perinæum, retarding the free circulation of the blood, is avoided, and it is more likely to retain its sentient property. Too much flexure of the head in the occipito-anterior, or in the occipito-posterior position, facilitates rupture of the perinæum, and should be rectified in each instance by the forceps with as little delay as possible. When the instrument has been applied and the soft parts are sufficiently dilated, the blades should be removed and the labour left to nature. After every labour the finger should be passed up the vagina and rectum to find if any laceration have occurred, and the extent. In every case of lacerated perinæum, where the rent has gone beyond the superficial structures, it should be immediately sewn together; if it be severe, the legs should be tied together, and the urine drawn off, the bowels being kept closed for a week. Sutures are not to be removed before the eighth or ninth day.

General Hints.—Braces are advised to be worn and corsets abandoned; excessive mental study is deprecated, and the erect attitude enforced; the latter position increases the obliquity of the pelvis, and diminishes the downward pressure on the pelvic organs. The catamenia should be regarded by women as a 'dower of health and beauty,' and mothers should so teach their daughters. The rest is adapted entirely to American ladies, as the abuses mentioned by the author happily do not exist in England to any such extent as to require notice.

W. C. GRIGG, M.D.

EPIDEMICS OF CHOLERA IN FRANCE.

(Continued from page 434.)

Notwithstanding the four epidemics of the disease that have ravaged Europe, a number of persons still hesitate to express their opinion on the origin and prevention of the disease. The theory of propagation of the disease by atmospheric currents suggests nothing against its course, to avert or destroy it. That of the spontaneous generation of cholera, in like manner, proposes nothing, nor does it indicate where is the source of the disease, what is the cause of its production, or under what combination of conditions it is produced. On the contrary, the theory of importation of the germ of cholera, of its generation in persons successively attacked, and of its transmissibility from one organism to another, not only points to the most rational therapeutic indications, but also indicates the hygienic means best calculated to diminish the severity of the disease, and to formulate the international measures by which new invasions may be prevented. The committee, having weighed all the evidence adduced by reporters, and judging from the experience of its members, adopt the opinion of transmissibility of cholera as the most natural. They observe the frequent occurrence of the disease in the proximity of places already attacked, and the rapid development of the disease in its subjects. They look upon the enormous dejections, often amounting to eight and ten litres in the space of a few hours, as only to be accounted for as arising from the serosity of the blood exuding through the surface of the intestines, but the albumen of which does not reveal itself by the ordinary reagents. They consider that the action of ferments, which attack by predilection the albuminous matters, is to transform and multiply themselves; that their corpuscles, soluble or insoluble in water, become suspended in the air, and are transported by that vehicle; that cholera originating in India is the product of a special miasm that has never been, and never can be, produced in France. This miasm, they consider, consists of subtle, impalpable corpuscles, probably organic in nature, but which have not yet been isolated by means of science. They penetrate into the living economy by the pulmonary and digestive organs, act as ferments, and produce in the albumen of the blood a modification of composition, the result of which is that the serum transudes by the surface of the intestine, thus causing decrease in the mass of the blood, the course of which in the capillaries becomes more and more slow. This morbid miasm becomes multiplied in the organism like molecules of ferments, is disengaged from the affected body chiefly by the alvine dejections, is suspended in the air, propagates itself to distances to affect new victims under particular conditions of temperature, which affect the powers and organic predisposition, or otherwise favour its effects. The primary source of the disease-producing agent resides in the patients, notably in the matter evacuated by them, not only during life, but after death. The emanations arising from the dejections become a direct and manifest cause of cholera in the vicinity of a patient, the more so when ventilation and cleanliness are neglected.

A second source resides in the dejections thrown upon refuse-heaps in streets or courts, as in villages, farms, and badly kept houses, and deposited in public or private latrines, communicating by means of pipes in different storeys. The emanations thus arising

from different points mixed with the air, and transported with it, become the means of propagation of the disease in different directions, according to the displacement of contaminated air and the intensity of morbid effluvia.

A third source, less apparent, proceeds from water contaminated by morbid dejections thrown upon public ways or into drains, and disengaged by subsequent rains, producing streams or percolating into the earth. Thus also cholera is induced by water from some wells, and by that from cemeteries passing into sources of supply for towns and villages.

A fourth source of the disease exists in body-linen, bedding, clothing, and other articles impregnated with the dejections of patients. These, being sent to a greater or smaller distance for washing, become the means of transplanting the morbid principle into places until then exempt, the dissemination taking place with more or less rapidity, according to the rapidity of transport.

Lastly, patients being moved, whether individually or in masses, as emigrants, armies, or caravans, bring with them cholera into previously healthy places, even to considerable distances, and also more or less rapidly, according to the rapidity of their movements and facility of transport.

In these various ways cholera may be caused and propagated. The conditions necessary for both may exist in the chamber of the patient or in the ward of an hospital, in the vicinity of a focus formed by a dépôt of alvine matters, whether removed to a distance from the affected or in their neighbourhood, or of those fleeing from infected localities, while the germs are as yet undeveloped in them, or have only produced cholera. The circumstances that the disease on some occasions continues for a long period, affecting a large number of persons, while in others it is speedily extinguished after making a few victims, depends upon the organic aptitude of individuals, such as we in fact have in consanguinity. It also depends upon the hygienic state of the inhabitants in regard to competency, temperance, cleanliness, distance from each other, or crowding of habitations, camps, or ships; according to the state of the locality where the germ is deposited—as to whether it is low, marshy, surrounded by hills, preventing free circulation of air, and so on. Thus we have an explanation of the disease being communicated to persons residing near patients suffering from it, of its extension in the same building, in a particular range of houses to leeward of a contaminated drain, whether in a village or town. A similar explanation may be given of the sudden occurrence of the disease at great distances without intermediaries, also in places considerably separated from those where it has first broken out, contact being thus traced in many outbreaks in appearance spontaneous. In this way we can explain the good results of removal of a body of troops from a contaminated locality, or a camp the ground of which is contaminated by putrid matters or dejections of cholera-patients, and establishing them in a new and more elevated locality, the soil of which is still untainted.

With regard to the treatment of those attacked by the disease, the best method is to neutralise the miasm, the primary source of the malady; but, the nature of that principle being unknown, the antidote has yet to be found. If science does not yet possess a special agent, it at least leads by way of induction to the employment of other agents, the utility of which has been demonstrated by experience. The principal

indications to fulfil are, to moderate the enormous evacuations of fluid which take place; to maintain the warmth of the surface; to favour the circulation of the blood. The hygienic measures to be adopted include the greatest cleanliness around the patients; free ventilation; the disinfection of clothing and dejections, and the speedy removal of the latter. Long continuance in the rooms or wards of the sick is to be avoided; the attendants should be often changed, and all superfluous persons sent away. As individual preventive measures, temperance and moderation in all things are to be observed; the state of the bowels must be attended to, and tendency to diarrhoea checked. Infected localities are to be abandoned when possible, and at any rate the departure of the timid will diminish the number of the predisposed, and thus lessen that of the victims. In respect to public hygiene, both before and after the outbreak of the disease, the public and private latrines, the drains and sewers, should be disinfected; all causes of putrid emanations should be removed. Special wards for cholera-patients should be established in hospitals, these being provided with free ventilation and ready means to change the bedding and linen as required. These wards should be maintained in the highest degree of cleanliness. If the epidemic be protracted, they should be changed from time to time, completely fumigated and whitewashed. The air of dead-houses should be purified as far as possible; the bodies of the dead should be speedily interred and surrounded by lime, or, as recommended in France, subjected to cremation. Water for use is only to be drawn from wells secured from pernicious underground infiltration, or from rivers above the point of discharge of drains and sewers into them. The quality of articles of food should be tested; tainted meat and unripe fruit should be condemned; and the sale of drinks supervised. House-to-house visits should be instituted, patients in the early stage of attack searched for, and treated or removed as the case may be. The dwellings should be cleansed. Paupers and tramps arriving from contaminated localities should be isolated in places set apart for the purpose, there receiving all needful care. Assemblages of troops, fairs, and markets are to be prohibited; troops should not march through infected places; they should be broken up and spread if already attacked, encamped in a healthy spot, and placed under shelter.

With regard to these measures, the committee observe that they are all excellent in their several ways; yet that more remains still to be done: other measures must be taken with a view to prevent new invasions of the disease. Of these, the best would unquestionably be, to check the development of the disease at its original source, and adopt the same sanitary measures as made the plague disappear from the delta of the Nile. If that be impossible, the arrival of the disease must be prevented by measures, the efficacy of which has been proved by experience. Quarantine should be applied to caravans leaving India towards the north-east of Europe, also to ships from India or other infected places. It is known that in 1865 the Mussulman pilgrims embarked at Jeddah carried cholera with them; they disembarked at Suez, proceeded thence to Alexandria by rail, and it was only after a new embarkation that they reached Beyrout, Smyrna, and Constantinople. With a view to prevent a similar occurrence for the future, it would be well to prevent the arrival by ships of pilgrims from Arabia into Europe.

HITZIG ON FERRIER'S EXPERIMENTS ON THE BRAIN.

Dr. Hitzig forwards to us the following memorandum of his reply to Dr. Ferrier's late contribution.

In the first July number of the LONDON MEDICAL RECORD, Professor Ferrier reviews my book, *Untersuchungen über das Gehirn*, and becomes thus a judge of his own cause, and makes full use of this circumstance. In reply to his long exposition, through which the reader will hardly learn the real contents of my book, I have to observe as follows.

I attacked Dr. Ferrier for two reasons—the one was of scientific, the other one of personal nature. My explications concerning the first point are laid before the eyes of the scientific world, and they will have to judge of its work, not Professor Ferrier. But it is by no means right for him constantly to declare his method of research to be better than mine, without ever having compared them, which I did, since I began my experiments.

With regard to the other point, I am forced to maintain decidedly my assertion that Ferrier, in his paper published in the *West Riding Reports*, has made the most extensive use of our experiments, without mentioning our names where he should.

Our paper contained the following new facts: 1. The indication of the points for the irritation of almost all the muscles; 2. The proof that after the irritation with the induced current, secondary movement (choreic movements, Ferrier) appear; 3. The proof that epileptiform fits may follow the application of this current; 4. The proof that the loss of blood destroys the excitability of the brain. Ferrier has reproduced all these facts, but he has only mentioned our names in connection with the first one, and that too in a manner upon which I will not again comment. We regard this as an unallowable method, and we reclaim once more our property. If one take away the above-mentioned facts from Ferrier's paper, inasmuch as it regards the cerebrum, there will not be found in it a *single essentially new fact*, even when one admits that all his statements are correct. For whether there are a few muscles more or less to be excited through the cerebrum may be of some interest, but does not affect the nature of the matter. These are the reasons for my bitterness against Dr. Ferrier's proceedings; it is that he takes the credit of the greater part of our researches for himself, and endeavours to diminish the value of the rest; not at all, however, the feelings which he ascribes to me.

Least of all have I any invidious feelings with regard to his conclusions, whether drawn correctly or incorrectly; these are entirely his property. But I must still doubt that the value of an article lies in these, rather than in the facts.

With reference to the three years, which, according to Ferrier, intervene between the first and second papers of my book, I must observe, that I was one year as a medical officer in France, and during this time did not lose sight of this subject, as article No. IV. of my book proves. Besides this, during these three years I have published two other articles in Reichert and Du Bois-Reymond's *Archiv*, and these too on the cerebellum, with the contents of which Ferrier seems to be still unfamiliar, although he reviews the book in which they are republished. Notwithstanding this, if I have not worked fast enough for

Dr. Ferrier, I am willing to submit to his criticisms for that, if only science is really advanced by the little which I do. Herewith I regard this discussion as closed for my part.

BUHL, HERING, AND FRIEDLÄNDER ON PHTHISIS, TUBERCULOSIS, AND INFLAMMATIONS OF THE LUNG.

Professor Waldenburg has reprinted from no. 25 of the *Berliner Klinische Wochenschrift* for the present year, his critical review of the works of Buhl, Hering, and Friedländer, enumerated in the foot-note.*

There is so much of general interest in this paper, that we think we shall be justified in making very copious excerpts.

Waldenburg says that the first work on our list is the most noteworthy of all the recent works on phthisis and tuberculosis. Its merits have made a second edition necessary in little more than a year.

At a time when the *dicta* of Laennec on these subjects were unquestionably received by the whole medical world, Buhl was an independent thinker and an original investigator. For many long years he stood alone, and critics scarcely deigned to learn his views, much less to appraise them at their true value; but of late his experiments have secured him the high position he so justly deserves. He was the first to defend the doctrine that miliary tuberculosis is a disease of absorption (*Resorptionskrankheit*); though this theory then wanted those satisfactory proofs which the experiments of ten years later have afforded. The specific nature of its contagion, which Buhl affirmed, has been contested of late on the ground of experiments on animals; but this does not lessen our admiration for Buhl, or the value of the services he rendered; for as early as 1856 he began to seek a basis for his theories in the *post mortem* room, and had even then begun to experiment on animals. The views he promulgated in his earlier publications on the nature of miliary tuberculosis in general, and of pulmonary phthisis in particular, were novel and peculiar. Though little recognised, he adhered bravely to them, with some modifications from time to time, and now has the satisfaction of seeing them widely diffused, well known, and very largely recognised as true. Buhl's doctrines may be briefly sketched as follows.

He draws very sharp, and not generally received distinctions, between different diseases of the lungs, as to whether they are superficial or parenchymatous; and again, whether they are lobar or lobular as regards their extent. Buhl thinks the real distinc-

tion between the latter is not the mere fact of the whole of one or more lobes of the lungs being attacked in one case, whilst in another only smaller segments of the lung are affected; the real difference is rather determined by the distribution of the blood-vessels. For it is acknowledged that the pulmonary circulation is of a two-fold type: the alveoli (air-vesicles, or air-cells) of the lungs receive their blood-supply from the pulmonary arteries; whilst the capillaries of the bronchi are derived from the bronchial arteries, and these ramify beyond the terminal bronchi, in the interlobular tissue (*im inter-alveolaren Gewebe*) and even reach the pleura. Inflammations of the lung will therefore either follow the ramifications of the pulmonary vessels, and so extend almost unchecked through the pulmonary parenchyma, thus becoming lobar; or on the other hand they follow the bronchi and the interlobular tissue, and thus form a sort of network of diseased lobules, alternating with and surrounding healthy lung-tissue; thus the disease easily reaches the pleura. Such inflammations, therefore, are lobular.

Lobar inflammations for the most part attack large territories of the lung, generally whole lobes; this, however, is not absolutely essential, for they may attack smaller portions of the lung, and yet retain their lobar character. Nor does he deny that lobular inflammations may extend to a whole lobe, or even a whole lung, without, on that account, deserving to be called lobar, for they do not falsify their character, since they correspond to the bronchial capillary network, and extend to the interstitial tissues (interlobular fissures) whilst in the very midst of the diseased lobules, a larger or smaller number of lobuli will be found intact.

Croupous pneumonia is always superficial, but yet it is a lobar inflammation. Catarrhal pneumonia, contrarywise, is truly superficial also, but it is always lobular. According to Buhl it is always an acute affection, and almost exclusively attacks the lower lobes—whilst he says it never gives rise to pulmonary phthisis any more than croupous pneumonia does, and even when inspissated secretions are deposited in the smaller bronchioles and alveoli, still the parenchyma of the lung always remains healthy. However, 'atrophic alveolar and bronchial dilatation (*Ectasie*)' and emphysema may occur as chronic sequelæ of catarrhal pneumonia. Properly speaking, Buhl thinks we are never in a position to admit the presence of an actual catarrhal pneumonia, since the alveoli of the lungs (air-cells) have, according to him, no regular mucous membrane, and even the epithelium which is certainly present, forming a lining to their interior, resembles rather the endothelium of a lymphatic vessel, than an actual continuation of the bronchial epithelium. Catarrhal pneumonias are, in actual fact, 'acute catarrhal bronchiolitis,' in which the lung participates by simultaneous oedema, and atelectasis, with local emphysema and atrophy, in consequence of the accumulated secretions of the separate terminal bronchi blocking up the lobules.'

Very different is the behaviour of what Buhl calls desquamative pneumonia. Far from being superficial this extends to the parenchyma, and is a lobar inflammation, which may, however, extend itself, secondarily, from the lung to the bronchi. This is essentially an inflammation extending into the parenchyma of the alveoli, and implicating their epithelium (endothelium), which grows wildly at first and then desquamates; so that the accumulated

* Inflammations of the Lung, Tuberculosis, and Consumption.—'Lungenentzündung, Tuberculose, und Schwind-sucht,' 12 Briefe an einen Freund. Von Professor Dr. Ludwig Buhl; 2 verbesserte Aufl. München. 1873: Rudolf Oldenbourg. 8vo., 169 pp.

Experimental and Microscopic Researches on Tuberculosis.—'Histologische und experimentale Studien über die Tuberculose.' Von Dr. Theodor Hering in Warschau. Mit 6 lithographirten Tafeln. Berlin: 1873. Hirschwald. 8vo., 112 pp.

Clinical Studies of Pulmonary Inflammations, with remarks on the Normal Epithelium of the Lungs.—'Untersuchungen über Lungenentzündung nebst Bemerkungen über das normale Lungen epithel.' Von Dr. Carl Friedländer. Berlin: 1873. Hirschwald.

On Localised Tuberculosis.—'Ueber locale Tuberculose.' Von Dr. C. Friedländer. Volkmann's *Sammlung*, no. 64. Leipzig: 1873.

epithelium, thrown off, and often mixed with the backward current of the bronchial secretion, quite chokes up the air-cells. Desquamative pneumonia may be met with in three different degrees and modifications: the lowest degree assumes the form of a local manifestation of a severe general affection, such as typhus, the acute exanthemata, pyæmia, etc., and may appropriately be called 'consecutive desquamative pneumonia.' The second, severest form is 'genuine desquamative pneumonia;' it is a 'localised expression of a general diseased condition, having its seat in the lungs.' It almost invariably begins in the upper lobes, but commonly goes on to involve the lower ones also; and it either runs an acute and fatal course, or has sub-acute or chronic lung-affections as sequelæ, which resemble, and in fact constitute, certain forms of pulmonary phthisis. Chronic fatty degeneration of the lungs, on the one hand, and cirrhosis of the lungs (Corrigan's disease) on the other, or the so-called chronic, interstitial pneumonias (fibroid cirrhosis, muscular cirrhosis, slaty induration of Rindfleisch, and lardaceous cirrhosis) are only varieties, which again lead to 'compensatory hypertrophic bronchiectasis,' with formation of chronic bronchial dilatations (*lit.* caverns), and is associated with fibrous adhesions of the pleuræ. The highest degree of desquamative pneumonia, and at the same time its commonest form, is caseous or cheesy pneumonia. The casefaction depends upon a kind of internal scabbing (*Verschörfung*) or necrotic process, and is brought about by the complete shutting off of the fattily degenerated tissue from the blood-stream through blocking and obliteration of the smaller arteries, in whose external elastic coat the inflammatory process specially localises itself, as if by preference (*gerne*) in desquamative pneumonia. The cheesy degeneration involves not merely the shed epithelial cells, but also the inflamed parenchyma itself. The casefied portions hardly ever contain inspissated pus. Thus the acute stage of caseous pneumonia consists in a 'necrotic desquamative nephritis.' Caseous pneumonia never (according to Buhl) originates in the catarrhal or croupous form. The chronic sequelæ, when neither death nor absorption occurs, may be the same as have been previously mentioned as following the genuine desquamative pneumonia (chronic fatty degeneration, cirrhosis, etc.). More commonly the cheesy portions become separated (*durch Abstossung*) from the healthy tissues, and an acute process of vomica-formation (*Cavernenbildung*) is set up; or the smaller cheesy foci may shrivel and wither, whilst the surrounding tissues become cirrhotic, and may occasion a chronic formation of cavities (*vomicæ*). Caseous pneumonia constitutes one of the commonest forms of phthisis, and may be considered as one form of peribronchitis. The latter commonly extends into the parenchyma of the lung, giving rise to lobular deposits (or foci). It may be divided into a simple inflammatory form, with a chronic course, peribronchitis simplex; and a subacute, suppurative form, peribronchitis purulenta. Buhl subdivides the former again, as follows: 1. Peribronchitis fibrosa; 2. Peribronchitis nodosa; 3. Lardaceous peribronchitis. Peribronchitis nodosa, as is well known, has been long mistaken for miliary tubercles (*vide* Dr. Baxter's Translation of Rindfleisch's *Pathological Anatomy*, New Sydenham Society, vol. ii. p. 29). Casefaction may easily follow, and when, as often happens, the parenchyma of the lung becomes involved, a special form of caseous pneu-

monia (the lobular) is the result. The same process of obsolescence, and breaking down, or pushing off of the cheesy matter, may occur. Peribronchitis nodosa necrotica, and lobular gangrenous pneumonia, lobular cirrhosis, and atrophic dilatation of the air-cells and bronchioles may also be sequelæ. The severest and most dangerous form of peribronchitis is the purulent or exulcerative variety. In this the parenchyma of the smaller bronchi is infiltrated with purulent matter, the walls soften and break down; the mischief goes on, extends to the lungs, causes deposits or foci of pus and cheesy matter in the lobules, which by and by ulcerate out and form cavities. The blocking of the bronchi thus caused induces lobular emphysema (Gairdner's view.—*Rep.*), which again in its turn may set up pneumothorax. Buhl considers suppurative peribronchitis the most frequent cause of pneumothorax; and very often of empyema and pyo-pneumothorax. It constitutes one of the commonest and severest types of pulmonary phthisis, and towards its close may be associated with some of the forms previously mentioned, thus hastening the fatal end.

(To be continued.)

ANATOMY AND PHYSIOLOGY.

GRUBER ON THE 'PROCESSUS FRONTALIS SQUAMÆ OSSIS TEMPORALIS' IN MAN AND OTHER MAMMALIA.—Professor Wenzel Gruber, of St. Petersburg, contributes a very elaborate monograph, illustrated by two large plates of twenty-two figures, to a recent number (tome xxi. no. 5, VII^e série) of the *Mémoires de l'Académie Impériale des Sciences de St. Pétersbourg*, entitled 'On the Connection of the Squamous Process of the Temporal Bone with the Frontal Bone in Man, and on the Analogy of its two Varieties in Man and in Mammalia.'

Chizeau, surgeon in the Hôtel-Dieu, of Nantes, was the first to put on record ('Observation anatomique sur une Articulation des Temporaux avec le Coronar,' *Roux, Journal de Médecine, Chirurg., Pharm., &c.*, tome xxxviii. Paris: 1772) this abnormality, which he observed on both sides of the skull of a male about forty years old. This he did, thinking that, in the case of a blow on the head, a surgeon, previously unaware of the peculiarity in question, might mistake the abnormally running suture for a line of fracture. Other observers, among them Owen, Henle, and Hyrtl, have since recorded a similar abnormality in the skulls of negroes and apes.

For a very long time—in fact for twenty-one years—Professor Gruber has been observing the above abnormal relation between the squamous portion of the temporal and the frontal bone. Out of 4,000 skulls in M. Gruber's collection this abnormality was seen in sixty; fifty-six out of these having belonged to males, and only four to females. It occurred on both sides in twenty-five cases; but in thirty-five only on one side—on the right side alone in eighteen, and on the left in seventeen cases.

Gruber recognises two forms of intercommunication, viz., (a) an immediate, and (β) a mediate form, through the intervention of an isthmus of bone—the 'processus frontalis squamæ ossis temporalis.' The immediate form was present only in two skulls, in one being bilateral, in the other on the right side only; while the mediate variety was seen in fifty-eight

skulls, occurring on both sides in twenty-four cases, and in seventeen cases on the right and left sides respectively. The abnormality occurs once in every sixty-six cases in entire skulls, but once only in ninety-four in a half-skull reckoning, the immediate form being to the mediate in the proportion of 1 to 27. The unilateral occurrence is of greater frequency than the bilateral, being in the proportion of $\frac{7}{12}$ to $\frac{5}{12}$.

Among lower mammals the absence of such intercommunication between the temporal and frontal bones appears to be constant in the Cetacea, Pinnipedia, Chiroptera, and Prosimiæ; while among the Glires, on the other hand, the communication is almost constantly present. Among the Feræ and Ruminantia, the communication is, with very few exceptions, absent, while among Pachydermata its presence is more frequent than its absence. In the Marsupialia the absence preponderates over the presence of this communication, while the reverse is the case among the Edentata. Among the Simiæ its absence and presence are about equal—the former perhaps preponderating. Among the Solidungula, and in the gorilla and chimpanzee among anthropomorphous apes, this communication is almost always at hand, while in the orang and gibbon its presence and absence are about equal.

Professor Gruber, after a minute discussion of details, concludes that the osseous communication in question consists essentially of a *process* from the squamous element of the temporal bone, and not, as might reasonably be urged, of an intercalated 'fontanelle-bone'—*ossiculum Wormianum*—fused with the said bone; and finally, that such intercommunication is a brute characteristic—nay, further, an ape-like character—a conclusion at which he has been expecting for several years to arrive.

MAGITOT ON DENTAL ANOMALIES.—Dr. Magitot contributes to a recent number of Robin's *Journal de l'Anatomie et de la Physiologie* (no. 3, May and June), a paper entitled 'Études sur les Anomalies du Système dentaire chez les Mammifères,' which is an abstract of material collected for a copiously illustrated work which he intends soon to publish. The anomalies of the dental system are treated of under the five following heads.

1. Definition, classification, and statistics.
2. Their occurrence in the various grades of mammals.
3. Their occurrence throughout the succession of human races.
4. The mode of their production, viz. their 'teratogeny.'
5. Their pathological and surgical aspects.

In the course of the paper a synoptical table of dental anomalies in the mammalia is given, which is, however, too long for reproduction here.

Dr. Magitot has collected no fewer than 1,150 instances from the museums of the various capitals in Europe, and finds dental anomalies thus distributed: Anomalies of form, 66; of bulk, 26; of number, 282; of position, 172; of direction, 178; of development, 93; of nutrition, 87; of structure, 152; of arrangement, 94.

He regards the phenomena of the hereditary transmission of an anomaly in the dental system as the result of sexual selection. This, however, rarely passes beyond two or three generations in mankind, but in the lower animals such anomalous characters can be fixed and rendered permanent by man.

J. C. GALTON

MEDICINE.

WILKS ON MANIA AS A SYMPTOM OF BRIGHT'S DISEASE.—Dr. Wilks (*Journal of Mental Science*, July, 1874) reports on three cases of Bright's disease in which maniacal symptoms have occurred.

Alluding to the asthenic state of dementia, common in cases of uræmic poisoning, Dr. Wilks states that he has reason to believe that in uræmia, certain aberrations of mind are occasionally found, but not such as would lead to perversions of moral feeling and of operations of the intellect; but rather to acute maniacal conditions.

The first case was that of a railway guard, who had been behaving in a strange manner all day, and at last had a fit and was brought to the hospital. He was then violently mad, and was put into the 'strong room;' he was the subject of marked gout, and had highly albuminous urine. After two days he became quite rational, and was then treated for this disease, which was evidently chronic, and due, in all probability, to a gouty, granular kidney.

A young woman, long the subject of Bright's disease, after having been in the hospital for some weeks, had several epileptiform fits, and at the same time was so maniacal that she had to be removed to the 'strong room.' After a few days these symptoms passed into those of lethargy, when she gradually resumed her original state.

A woman beyond middle age, in an extreme state of cachexia in connection with long-standing morbus Brightii, suddenly lost her reason, became noisy, threw herself about, and was obliged to have side boards fixed to her bed. She remained in this wild, senseless condition for a week, when she again became quiet, subsequently dying from the effects of atrophied kidneys.

Dr. Wilks speaks hesitatingly of maniacal symptoms being caused by uræmia, since a number of other causes, such as an epileptic condition of the brain, or even some impoverished condition of that organ in connection with diseased blood-vessels may be present, and also because other good observers have not, as yet, described such symptoms as characterise the brain disturbance of Bright's disease.

HENRY SUTHERLAND, M.D.

GERHARDT'S PERCUSSION-SIGN OF CHANGE OF PITCH.—Dr. A. Weil directs attention to a percussion-sign first described by Gerhardt in 1859, and apparently seldom or never taken advantage of in the physical examination of the chest, namely, change of pitch of the tympanitic (*tympanitisch*) note yielded by a circumscribed spot of the thorax with change of posture of the patient (*Berliner Klinische Wochenschrift*, 1874, no. 7). The author is careful to distinguish this phenomenon of change of pitch from two others which may present themselves under different circumstances. The first of these is 'Wintrich's change of pitch,' and is familiar as the alteration of pitch occasionally observed over pulmonary cavities, according as the mouth, or the mouth and nostrils, are open or shut. The second is 'Biermer's change of pitch;' it is related to the phenomenon which is the subject of the present paper, and depends upon the alteration in the length of the longer diameter of a cavity (with fluid and gaseous contents), by alteration of the posture of the patient.

Gerhardt's phenomenon appears to differ from that last described only in respect of the circumscribed

area over which it is elicited. In explaining its rationale, Weil says that a tymphanitic note occurring at a limited spot of the thoracic wall cannot possibly change in pitch with the posture of the patient, unless there lie behind the percussed spot a sonorous cavity the longitudinal diameter of which is diminished or increased with alteration of the patient's position. And such a lengthening or shortening cannot possibly occur unless there be present in the cavity not only air but a mobile fluid, which, in obedience to the laws of gravity, ever occupies the lowest place. In other words, Gerhardt's phenomenon depends upon the same principles as Biermer's does in pyo-pneumothorax, and indeed, may be said to be present when the sign described is elicited over a limited pyo-pneumothorax.

Two interesting cases are recorded in illustration, both ending in a confirmatory *post mortem* examination.

Weil maintains that this phenomenon is more than an interesting sign of the exact architecture of a well marked cavern; it is available for the recognition of a cavern when other 'cavernous signs' fail. Not one of these so-called signs is exactly pathognomonic, and this objection will not apply to Gerhardt's phenomenon should it be discovered. It indicates with certainty the presence of a somewhat large pathological cavity filled with air and fluid. Unfortunately, in the majority of caverns, all the conditions for the development of the sign are not present; the cavern may be more of a spherical shape, or its walls may be very irregular, or the fluid may not possess the necessary mobility; or there may not be the proper quantitative relation between the elastic and the fluid contents. Finally, the sign may vary in its occurrence from day to day.

SURGERY.

COLLETTI ON SIMPLE LIGATURE AS A MEANS OF PREVENTING LOSS OF BLOOD.—In *Lo Sperimentale* of June, 1874, Dr. Colletti makes a brief communication to the following effect.

He had occasion to perform amputation of the thigh on a man who had his leg crushed by a large block of marble. The patient had already lost much blood when he was brought to the hospital. Dr. Colletti applied three turns of a narrow bleeding bandage round the upper part of the thigh; this had the effect of arresting the hæmorrhage, and amputation was performed almost without loss of blood. The large vessels were tied; on removing the bandage hæmorrhage took place from one small artery only, and was arrested by torsion. Dr. Colletti relates the case to show that an *elastic* cord is not absolutely necessary.

BERGONZOLLI ON REMOVAL OF CANCER OF THE PENIS BY THE KNIFE AND BY LINEAR ECRASEMENT.—Dr. F. Bergonzolli, in a pamphlet quoted in

the *Gazzetta delle Cliniche* for June 23, relates the case of G. B., aged fifty, who had cancer of the penis, without engorgement of the inguinal glands. The only means of relief being removal, this was performed by Dr. Bergonzolli: the dorsal artery, which was very large, having been first tied. Twenty days after the operation, granulations appeared at the upper part of the urethra, and increased, presenting distinct signs of malignancy. The parts were energetically cauterised with Canquoin's paste; the eschar fell off at the end of ten days, leaving a sore with a healthy aspect, which healed in a few weeks under simple treatment.

Eight months afterwards the patient came back to hospital, the disease having returned. His skin had an earthy yellow tint, and he was much emaciated. The inguinal glands on both sides were rather enlarged and hard. The sore which occupied the stump of the penis was two inches wide, had raised edges, and was the seat of lancinating pains. Within the urethra induration extended to about two centimètres from the bulb. By a circular incision, two centimètres from the limit of the sore, the skin corresponding to its raised edge was removed, the subjacent induration being left. Above this, the chain of the *écraseur* was applied, while an assistant drew the stump of the penis forward with Museux's forceps. The affected portion was strangulated in a few seconds; a gum-elastic catheter was introduced into the bladder, and the wound was dressed with charpie. At the end of eight days, Dr. Scarenzio applied a twisted suture with three pins; one of them was thrown off at the end of three days, and the two others two days later. Healing went on regularly (there being, however, two febrile attacks), and the patient was able to leave the hospital in two months. The yellow tint had disappeared, perhaps as a result of the use of arsenic. At the end of eight months, there was no return of the disease.

A. HENRY, M.D.

REEDER ON STRANGULATED UMBILICAL HERNIA, WITH LOSS OF PORTION OF INTESTINE.—Dr. J. N. Reeder (*Chicago Medical Journal*, June, 1874) reports the case of a woman, aged about sixty-eight years, who, when first seen, was found bathed in a cold, clammy perspiration, with feeble pulse, vomiting fluids of a stercoraceous odour; all her symptoms, in short, pointing to impending collapse. Upon exposing the abdomen an umbilical hernia was found, of the size of a child's head, the integuments covering the tumour being highly inflamed, of a dark, livid colour, and on the verge of giving way from excessive distension. Upon inquiry it was ascertained that the hernia had existed for thirty years, and she had experienced frequent attacks similar to the present, which had always been relieved by fomentations. Strangulation had now occurred three days previous, and meanwhile no medical aid had been called, though her sufferings had been excessive. The operation for artificial anus presenting the only hope for relief, an opening was made through the integuments and tissues beneath, exposing the intestine, the walls of which immediately gave way from distension, giving exit to the feculent and gaseous contents of the loop. The incision in the integuments was then enlarged, exposing fully the interior of the tumour, which was found to be in a gangrenous condition, a well-defined line of demarcation appearing at the point of exit from the abdomen. This gangrenous loop was next separated and removed,

and was found to be composed of fourteen inches of the transverse colon, with a large portion of omentum. The operation was followed by a rapid disappearance of all the distressing symptoms, and recovery speedily ensued. At a subsequent date the edges of the two ends of the colon were refreshed and approximated by means of wire sutures, the result of which was that a complete union was obtained, so that the entire contents of the colon again made their exit at the rectum. It is now over two years since the closure, and the woman is in perfect health, being able to do her own housework.

MATERIA MEDICA AND THERAPEUTICS.

FLEMING ON THE TREATMENT OF RABIES AND HYDROPHOBIA.—According to Mr. G. Fleming (*Rabies and Hydrophobia; their History, Nature, Causes, Symptoms, and Prevention*; reviewed in the *British and Foreign Medico-Chirurgical Review*, July, 1874) the treatment of rabies and hydrophobia is in some respects unsatisfactory, because the disease, either in man or the lower animals, is necessarily fatal. Mr. Fleming does not pretend to have discovered any method of cure, and he condemns the conduct of those persons who, from credulity or ignorance, believe in the efficacy of remedial measures when once the malady has declared itself, and he is still more strong in his condemnation of those who, from interested motives, vaunt the discovery of specific cures for hydrophobia. But while he admits, as all must do, the incurable nature of the disease, he, nevertheless, deprecates unnecessary alarm in the minds even of those who have been injured by the bites of mad animals, because it does not necessarily follow that hydrophobia will ensue in all such cases. The somewhat prevailing practice of immediately and indiscriminately killing the animal which has inflicted the injury is obviously a foolish and mischievous one, because it is by no means always certain that the brute is really mad, and thus the human victim may be exposed unnecessarily to the torture of apprehension when, perhaps, no cause of fear exists. The advice given on this point by Mr. Fleming is that a dog suspected of or attacked by rabies, or one which has been bitten by a rabid animal, should not at once be killed and buried unless there be reason to suppose that *no person has been wounded by it*, but if a person have been bitten, then the animal should only be killed if the malady be undoubtedly present. If the case be only a suspicious one, it is well not to kill the dog immediately, but to keep it securely confined and to watch it carefully, so as to observe whether rabies really supervenes; the time required for the development of the symptoms is not long, and when they are developed the animal must be killed and buried. If, too, an animal suspected or affected with the disease escape from its owner, or from any locality, it is the urgent duty of every one to warn the police and cause strict precautionary measures to be observed.

In the case of the human subject the local preservative treatment, which alone is assuredly efficacious, must be resorted to before the absorption of the virus; and, in order to be efficacious, this treatment must be prompt, and the poison must be removed by suction, squeezing, washing, and cauterisation. If

the bitten part be within the reach of the mouth of the individual attacked, he should himself at once suck the wound vigorously, or allow a bystander to perform this duty; and it is to be observed that the danger of so doing is not very great, for, as is well known in the case of certain poisonous agents of animal origin, they are not absorbed by the digestive canal unless there be some abrasion on the mouth or lips. Expression, washing, compression, and cupping may all be employed; but, useful as these measures are, they ought to be supplemented as soon as possible by cauterisation of the injured parts, either by a powerful heat or by chemical action. Mr. Fleming does not hesitate to recommend the hot iron as undoubtedly the most convenient and perhaps one of the most effective agents that can be employed to destroy the saliva and the tissues tainted by it; and the actual cautery has this further recommendation, that several articles in common domestic use will furnish the necessary instrument. Of the chemical caustics the most efficacious are the strong fluid acids, as the nitric, hydrochloric, and sulphuric; other caustic agents, as nitrate of silver, corrosive sublimate, and chloride of zinc; and strong alkalies, as strong ammonia, and caustic potash and soda. Excision, also, is a very efficacious measure, but the greatest care should be taken that every portion of flesh likely to have been in contact with the saliva be removed. Mr. Fleming gives some very valuable and interesting tables, showing the number of cases where immunity has followed the bites of rabid animals treated by cauterisation, and of cases of death where no such precaution has been taken, and the results, as might be anticipated, are strongly in favour of the adoption of such prophylactic measures.

Mr. Fleming offers the following suggestions as to the general plans of prevention which ought to be adopted by local authorities in reference to hydrophobia. In addition to taking due care of the health of dogs when employed for useful purposes, he recommends the diminution of the number of useless dogs; and he justly urges this diminution in the case of dogs kept by poor people, both on the ground of the propagation of disease by ill-fed and dirty creatures, and also because the consumption of food required for their maintenance represents so much aliment subtracted from the poor people themselves. But, while thus advising the destruction of useless animals, he no less condemns the practice of keeping pleasure dogs by the rich, which also are a source of danger and an act of mere extravagance, and to lessen the number of such useless pets he proposes the imposition of heavy taxes. On the important subject of *muzzling*, which is somewhat indiscriminately adopted in some places, and altogether neglected in others, there is much to be urged on both sides; but, on the whole, Mr. Fleming is in favour of this measure, although recommending that the muzzle used should be efficient and humane, so that, while it prevents the animal from doing any mischief, it should allow sufficient space for it to breathe freely.

GUÉRIN ON TRANSFUSION.—In a recent discussion in Paris on Transfusion (*Bulletin de l'Académie de Médecine*, May 26) Dr. A. Guérin described his operation of putting two dogs side by side, and by means of proper instruments—applied to arteries and veins—placing their circulatory systems into such a communication that the blood of the one (after the Siamese-twins fashion) circulates through

the blood-vessels of the other. In one instance—one dog being smaller than the other—it soon became plethoric and passed bloody-stools. Dr. Guérin thinks the operation might be employed with advantage in man—that an anæmic individual might be thus anastomosed with a plethoric with benefit to both. He ignores the dangers of opening an artery, and the entrance of air into the vessels, but he admits the danger of a healthy person receiving into his system blood more or less morbid. He stated, however, that he was ready to carry out the operation on himself on the first occasion that offered. [The operation on animals is not new. It has been performed by Blundell and others, but has been regarded, and will probably still be regarded, more as an interesting physiological experiment than as having any practical value.—*Rep.*]

HENRY M. MADGE, M.D.

INHALATION OF CHLOROFORM IN STRYCHNINE POISONING.—In some reports of practice in the Brooklyn City Hospital (*New York Medical Record*) a case is recorded in which a man took five grains of strychnine with suicidal intent.

Before admission to the hospital he was given twenty grains of sulphate of zinc with effect. He had had repeated convulsions, and, while being taken from the ambulance, was seized with one of tetanic form, which plainly showed strychnine poisoning. Every muscle was rigid, and tetanus complete. Opisthotonos, irregularity of pulse, varying from 120 to 140 in the minute, with all the accompanying symptoms, were noticeable.

He was immediately placed under the influence of chloroform. The convulsions ceased from the commencement of the anæsthesia, under which the patient was fully kept for three hours. The chloroform was then removed, but the patient did not awake until six hours afterwards. He recovered.

TREATMENT OF CHRONIC DIARRHŒA.—In the Brooklyn City Hospital (*New York Medical Record*), in cases where the epithelium is stripped from the tongue, and the patient presents the cachexia of the disease, good results have been obtained by the administration of powdered ipecacuanha, in twelve-grain doses, three times daily, given mid-time between meals to prevent emesis.

This is continued until the stools are of a perfectly serous nature, when the ipecacuanha is discontinued, and four grains of oxide of zinc and six grains of extract of quassia are given in capsule three times daily.

Guarana in powder has been used in similar cases with apparently very good cures; but as it is impossible to keep trace of the patient, the permanency of the cure is not established.

TREATMENT OF ERYSIPELAS.—In the practice of the Brooklyn City Hospital (*New York Medical Record*) the following has proved efficacious as a local application in erysipelas:—Acetate of lead, carbonate of magnesia, camphor, each twenty grains, water one pint.

PROFESSOR WAHLBERG, of the Faculty of Law, has been chosen Rector Magnificus of the University of Vienna.

A PARTY of the members of the International Sanitary Congress in Vienna have had the honour of dining with the Emperor of Austria at Schönbrunn.

OPHTHALMOLOGY AND OTOLOGY.

MOOREN'S OPHTHALMOLOGICAL COMMUNICATIONS FROM THE YEAR 1873.

These are observations made by Dr. Albert Mooren, of Düsseldorf in a clinique, which, from October, 1856 to the end of 1873 had an attendance of 70,469 patients, the year 1873 contributing 5,768 towards that amount.

In *blepharadenitis* Dr. Mooren considers that epilation is carried to too great an extent, and is often a source of new irritation, protracting the already inflamed condition. He thinks it is unnecessary, as frequent fomentation of the lids causes the cilia to fall out of themselves. When irritation has been caused by this 'impetuous' treatment, he finds the application of a cataplasm for about half an hour at a time, of the greatest service.

He cannot find a connection between *xanthelasma* of the lids and any constitutional affection. If desired on account of a cosmetic effect, he removes the parts by means of Cooper's scissors.

In only one case of *Basedow's (Graves's) Disease* has Dr. Mooren seen a disturbance of vision. The regulation of the menstrual abnormalities was first attempted; and after that, iodine was given as a calumative of the sympathetic system, and bromide of potassium with lupuline where the heart's action was excessive. Preparations of iron and veratria were employed also with benefit.

Where *obstruction of the lachrymal duct* is simply the result of a catarrhal affection, the application of fomentations, lukewarm injections with a few drops of carbolic acid solution in them through the canal, and the frequent emptying of the sac by pressure, he considers the simplest and most effectual treatment.

For the *obliteration of the sac* he finds daily cauterisation of the sac by nitrate of silver in substance the best, after having tried nearly all methods.

A case of *cysticercus* under the conjunctiva, simulating a pus accumulation in the superior rectus, occurred in a girl of twelve years of age.

Chronic conjunctival affections, he agrees with the older authors, have an intimate connection with constitutional affections, and are not merely local affections. During the conjunctival inflammatory process he holds the application of cold to be an important part of the treatment, but this only so long as there is no cedematous swelling of the lids, when the use of warm linseed-meal or oatmeal fomentations is demanded.

Dr. Mooren, during 1873, saw from twenty-five to thirty cases of the *amyloid degeneration of the conjunctiva* of Professor von Cettingen. He could not determine the cause.

He believes that his already expressed opinion that cold wet days, with great changes of temperature, are peculiarly favourable to the development of *diphtheritis* is correct, and that *conjunctival diphtheritis* loses its intensity and danger the further westward it occurs from the Elbe or the Rhine. The statement that it does not occur in Belgium, he says, is a mistake.

In the cases of *brown punctiform precipitations* on the posterior layer of the cornea, which occurred to him once in about every 6,000 cases, he could discover neither subjective nor objective symptoms of irritation.

Of *cataract-extractions* $4\frac{1}{2}$ per cent. made during 1873 by Von Græfe's method were lost, and he gives from 6 to $6\frac{1}{2}$ per cent. as his percentage of loss from 1,500 operations by this method. In 13 of these cases he performed iridectomy with the purpose of creating conditions which would remove any danger arising from the artificial hastening of the maturity of an unripe cataract. Every case succeeded, and three of them had both eyes operated on. The method of procedure was as follows. From 18 to 21 days after an iridectomy had been made, the coloboma of the iris having been dilated by atropine, the lens-capsule was opened by a discission-needle in about three-fourths of its circumference. Great care was taken not to hurt the iris in any way, and disturbance of the lens-substance was avoided as much as possible, so as to obtain a homogeneous and perfect cataractous formation, which is not so apt to cause irritation of the uveal tract as when the lens is unequally hardened. After the full reaccumulation of the aqueous humour, instillation of atropine was resorted to, and the pupil kept under the influence of it till the extraction, which was performed in from 8 to 21 days, according to the arrival of the cataract at maturity. He says it is particularly applicable to posterior polar cataract.

The *cobweblike brown opacities of the capsule*, which are often only to be recognised by oblique illumination, are best removed from the pupillary region by incising them through their whole length, with a lance-shaped knife. He has done this seven times, and has had no alarming reaction.

Iridotomy, as performed by Wecker, he considers a great advance; and after having performed it in twenty-two cases, he is satisfied with the results. In cases of traumatic cataract, where bruising influences have been at work and new choroidal inflammations are liable to be set up, he considers it cannot be sufficiently praised.

A case of *monocular retinitis pigmentosa* passing into absolute amaurosis occurred, the other eye being affected with atrophy of the optic nerve, but not having the slightest trace of pigmentation. He believes that perivasculitis is the cause of the affection more frequently than is at present supposed.

In cases of *visual disturbance*, with marked congestive or inflammatory disturbances of the brain or its envelopes, leeches, application of ice to the head for from one-and-a-half to two hours at a time, and setons in the neck were the remedies he relied upon.

Nitrate of silver given internally he praises highly as the remedy in an *atrophic condition of the optic nerve* from neuro-retinitis. The injection of strychnia in such he has seen no good results from, though he recommends it in cases of anæsthesia of the optic nerve, or torpor of the retina.

In cases of *nystagmus* he is dissatisfied with the results of partial tenotomy or full detachment of the sinew, and has given up interfering with them. Two examples of this affection happened in miners, where the nystagmus only occurred during a modified light, and completely disappeared during exposure to daylight; while in the case of a child the nystagmus increased by increasing the light.

W. LAIDLAW PURVES, M.D.

CHISHOLM ON A CASE OF FORMATION OF CATARACT IN TWELVE HOURS.—Dr. Chisholm (in the *Richmond Medical and Chirurgial Journal*) reports the following curious case. A lady, aged

sixty-five, presented, when examined with the ophthalmoscope, faint striæ in the two lenses. For fifteen months Dr. Chisholm had her under observation, and examined the eyes repeatedly, without being able to discover any change. Having examined her carefully one evening, and having found the appearances just as usual, he was astonished the next morning to find the lens quite opaque and sight gone. He at once extracted the cataract, and the patient did well.

PUBLIC HEALTH.

MR. SIMON'S REPORT ON PUBLIC HEALTH PROCEEDINGS.

Mr. Simon has presented the following report to the President of the Local Government Board.

1. As the officer appointed to make report to the Local Government Board, for the annual information of Parliament, in relation to matters concerning the Public Health, and to the inquiries and other proceedings which the Board, under the Public Health Act, 1858, may have directed in such matters, I beg leave to submit to you that for the past two and a half years, and particularly during the last year, the circumstances of official and administrative transition, consequent on the Acts of Parliament of 1871 and 1872, have been such that no consistent scheme of report in general relation to the sanitary interests which are under the Board's superintendence has been possible to me; and the present Report, which regards the year 1873, must necessarily, even more than its two predecessors, illustrate the difficulty of the unsettled circumstances.

2. Of the Board's business during the year 1873 in matters of concern to the public health, the largest and incomparably the most important part was that which related to the action of local sanitary authorities under the Act of 1872 in appointing their officers of health and inspectors of nuisances. This action, which the legislature, at the instance of the Royal Sanitary Commission, had made obligatory on all the local authorities, and which included as its most important feature that for the first time the medical profession throughout the country was to be brought into official use with a view to the better prevention of disease, was, at least in part, even in the terms of the statute, tentative*; and evidently the discretion to be used by each authority in its compliance with the terms of the law would, for better or worse, be of great future consequence to the local working of the Sanitary Acts, and to eventual public estimation of the new machinery. The Board throughout the year 1873 was advising local authorities in detail on particular schemes of appointment and duty for the above-mentioned sanitary offices: but this branch of business was exclusively in the hands of the non-medical officers of the Board, and I therefore do not here attempt to give any account of the proceedings or their results.

3. Of the medical inspections which were made during 1873 in regard of local sanitary questions, and which under the peculiar circumstances of the year were but forty-two in number, I subjoin a detailed list (given in a Appendix). In one of them the inspection related to a question of hospital-accom-

* In regard of rural sanitary districts, the first appointments of medical officers of health and inspectors of nuisances under the Act must be for a period not exceeding five years.

modation, and in one to certain manufacturing processes causing nuisance to several districts; but otherwise universally the ground of inquiry was some more or less important presence of disease; and the last column of the subjoined table will enable some judgment to be formed as to the extent to which the powers of the authorities had been exercised, and the duties fulfilled, in the particular instances referred to. I may add that, as some of these local inquiries were in cases of much sanitary interest, I propose bringing their results before you, as soon as practicable, in a separate supplementary report.

4. One considerable inquiry, of a sort different from the above, was in progress during part of the year, but has not hitherto been completed. It has in view to examine the sanitary conditions under which certain industries are now carried on, as compared with the lung-diseasing conditions which existed in 1860-64, when special report on them was made to the Privy Council; and I have to state that during 1873 contributions towards the making of that comparison were furnished in inquiries of the Medical Department as follows: by Dr. Ballard in respect of metal trades at Sheffield, Wolverhampton, Alcester, Bromsgrove, and Birmingham; by Dr. Blaxall in respect of glove-making at Yeovil; by Dr. E. Smith in respect of tailoring and printing in London; by Dr. Thorne in respect of pillow-lace manufacture at Newport and Towcester, of machine-lace and hosiery manufacture at Nottingham, Radford, and Basford, of straw-plaiting at Tring and Berkhamstead, of silk-weaving at Leek, of silk-weaving and watch-making at Coventry, and of hosiery manufacture at Leicester and Hinckley.

5. The business of the Board as to vaccination in 1873 regarded, as usual, the following matters:—(a) the proceedings of local authorities and officers under the Vaccination Acts; (b) the provisions by which the national supply of vaccine lymph is maintained; and (c) the arrangements which give effect to the Order of Council regulating the qualifications of public vaccinators. (a) In superintendence of local proceedings under the Vaccination Acts, the Medical Department inspected 1,617 vaccination-districts in 354 Unions or parishes: each district-inspection involving, first, an inquiry into the state of vaccination in the district; secondly, where requisite, a notification to the authority as to defects found in the local administration of the Acts, with advice as to the changes required; and thirdly, in suitable cases, a recommendation of the vaccinator for pecuniary award, under section 5 of the Vaccination Act, 1867, out of moneys voted by Parliament for the purpose, and of which in 1873 an amount of 8,508*l.* 17*s.* 4*d.* was thus distributed. Particulars of the vaccination-inspections of 1873, and of the awards made to public vaccinators, are subjoined in Appendix No. 2. (b) Acting as National Vaccine Establishment, the Medical Department supplied vaccine lymph in answer to 9,569 applications. Particulars as to the sources whence this lymph was derived, and as to the applicants who received it, are given, with other statistics of the National Vaccine Establishment in Appendix No. 3. The stations supplying lymph for the public service were as usual specially inspected. (c) The several educational vaccinating stations, established with reference to the Order of Council which regulates the qualifications of public vaccinators, require in this relation to be inspected on behalf of the Board, and were, as usual, so inspected in 1873; but as they are for the

most part stations which also supply lymph for the public service, and as the efficiency of a station for the latter purpose greatly concerns its efficiency for the former, the inspection of them in one relation conveniently combines with inspection of them in the other, and in practice the two objects are attained in single inspections.

6. Lastly, I have to report that in 1873, and particularly during much of the second half of the year, Asiatic cholera was more or less prevalent in many parts of continental Europe, and sometimes—as at Paris, Havre, Rotterdam and Antwerp—in places which have constant and easy communication with England. In our relations to cholera on the continent of Europe there are at present some points of interest on which I may have occasion to submit to you a supplementary report: but I need not here do more than refer to the Board's actual proceedings as to cholera during the year on which I am reporting. In July, 1873, in view of the then circumstances, the Board issued (instead of an order which had been issued in 1871 by the Lords of the Council) an amended order, prescribing rules for the detention and examination of ships suspected of choleraic infection, and for dealing with cases of actual infection. (See Appendix, No. 4.) The Board also circulated among the local sanitary authorities of England a memorandum (Appendix, No. 5), which at the Board's desire I had prepared, on the precautions generally proper for local adoption under the circumstances; and particular communications on the subjects of local arrangements were also had by the Board with several of the sanitary authorities of ports. In a few cases, namely, three times in the Thames, twice at Liverpool, once at Southampton, and at least once at Swansea, the local arrangements were tested by infectious arrivals; and in most of these cases, as well as in several instances of false alarm, local inquiry was made by inspectors from the Medical Department: Dr. Buchanan, Mr. Radcliffe, Dr. Gwynne Harries and Mr. Power.*

* In one case, among those which particularly concerned London, the danger was extremely great. On July 28 a ship from Hamburg landed at Blackwall a body of eighty-two Danish and Swedish emigrants, in destination for New Zealand. During the voyage no sort of illness, except sea-sickness, had been noted among them, and therefore no objection to their landing had been raised under the Board's recent order; but almost immediately afterwards, when, to await re-shipment, they had settled themselves in various lodging-houses in Whitechapel, and were legally in the position of ordinary residents in London, it became evident that cholera was among them; and the Board's first information of this state of the case was due to the courtesy of a private medical practitioner who had been called to the sick. As soon as his letter was received by the Board, communication on the subject was had by the Medical Department with the authorities and others who were concerned, and by great exertions of all, under a state of law in which everything depended on voluntary exertions on one side and absence of objection on the other, the emigrants by July 31 (the day on which they were to have been re-shipped for New Zealand) were collected and placed in isolation on the port-authority's hospital-ship 'Rhin,' off Gravesend, to remain there under medical care. Then the houses where they had been temporarily lodged, and which meanwhile had been under close observation by the Whitechapel officer of health, Mr. Liddle, were finally disinfected. Of the eighty-two emigrants, twenty-eight sickened and eight died; but to our own population there was no extension of the disease. The removal was managed by the emigration agent, to whom the great importance had been explained of getting all the emigrants together into suitable quarters where their state of health could be medically watched and cases of incipient cholera be isolated; but this action, taken by him with the co-operation of the recently appointed able health-officer of the port, Mr. Harry Leach,

The above account refers, as I have stated, to a period of official and administrative transition, during which it is impossible to represent the Local Government Board as directing inquiries under the Public Health Act, 1858, in any definite relation to the new sanitary system of the country; but with the end of the year 1873, that period of transition may be deemed to have nearly accomplished itself; and I may hope that, before the next season arrives for the submission of the Annual Report under the Act of 1858, it may have become possible to begin in a really useful sense such new succession of reports as the changed conditions of sanitary administration seem henceforth to require.

If, in that hope, I may venture to indicate from beforehand the purposes which it seems to me the reports under the Act of 1858 must in future be expected distinctively to fulfil, I would say that, whatever else they may be expected to do, at least they must be expected to set forth the knowledge which the Board, through its department of sanitary inquiry, obtains, with regard to the practical effect of the laws which are in force for the prevention of disease throughout England. It is the common conviction of persons who have most studied the subject, that the deaths which occur in this country, (now about half a million a year) are by fully a third part more numerous than they would be if existing knowledge of the chief causes of disease were reasonably well applied throughout the country; and I need hardly add that, if thus some 125,000 cases of preventable suffering annually attain their final record in the death-register, that vast annual total has the terrible further meaning that each unit in it represents an indefinite (often very large) other number of cases, in which preventable disease, not ended in death, though often of far-reaching ill-effects on life, has also during the year been suffered. The Local Government Board, viewed as a central board of health, and the more than 1,500 district authorities which, each with its appointed medical officer of health, locally administer the health-laws, may be regarded as having had their respective functions assigned to them in special and systematic relation to that state of things; and it will be peculiarly with regard to that relation—namely, as rendering account of the central share of the responsibility, that the future annual reports of the holder of my office will, I apprehend, have their essential meaning.

In the sanitary administration of England, there are certain prescribed cases (chiefly in regard of local powers of rating, mortgaging, and bye-law making) where the local action cannot be taken without previous express approval of the central authority; and no doubt the central authority, in its exercise of that responsibility, has often been able to influence very advantageously the course which local authorities have proposed to take. Also it possesses, in supposed reserve for great epidemic emergencies, a power to issue directions for certain purposes under the Diseases Prevention Act,

was without any support from law. That he was able to do as advised, and to do it in such a way as to transfer an immense danger from the heart of London to a comparatively safe distance, was due to the goodwill of the port-authority, who made their Gravesend ship available for the relief of Whitechapel; and it seems to me that by acting in that liberal spirit the Corporation of the City helped London out of a serious difficulty. Dr. Buchanan, assisted in part by Dr. Gwynne Harries, was the inspector who visited in this important case.

1855. But with exception of such special cases, the function of the central authority in regard of local sanitary action is primarily one of mere observation and inquiry. Not itself authorised to interfere in such action except where the results are at fault, it watches and interrogates results; and it is distinctively in this relation to the sanitary interests of the country that the Local Government Board will be represented by its ordinary proceedings under the Public Health Act, 1858. For the eventual test of local sanitary administration will be the success with which it prevents disease; and, in each case where the preventable disease is not prevented, the Local Government Board can, by skilled inspection under the Public Health Act, 1858, satisfy itself as to the circumstances and causes of the failure: giving thereupon such skilled advice, or proceeding in certain extreme cases to issue (under § 49 of the Act of 1866 or under the Diseases Prevention Act) such orders and directions, as the particular occasion may require.

What standards of success in disease-prevention ought to be taken as satisfactory by the local authorities which now have to act in that matter, and by the central authority which has to superintend their action, is a question on which I need not here submit more than very few general observations. Our large annual total of preventable deaths receives probably from most or all of the fifteen hundred sanitary districts of the country contributions, larger or smaller, which in their respective degrees are evidences of sanitary unsuccess; and I would therefore point out, as of very important bearing on the whole tone of sanitary administration, that in the death-accounts which have henceforth to be critically examined by both central and local authorities, figures which arithmetically make but little show may, for administrative purposes, have immense meaning. One or two deaths by enteric fever, noted in a quarterly return of the Registrar-General in regard of some village or small country town may in hundreds of instances correspond to long-continued local conditions of scandalous filth and unwholesomeness: one or two deaths by scarlatina or small-pox, almost unnoted in regard of some considerable town, may represent the beginning of what, three months later, will be a terrible epidemic, agitating the community with distress and fear, and adding prodigiously to the whole year's death-rate of the place; and it is with reference to considerations like these that records of even single deaths will now have to be medically read and interpreted. In regard of such epidemic visitations as are aptest in this country to excite local alarm, and to be felt as conclusive appeals for central interference, it may appear a mere truism to say that, in proportion as the disease is present, the time for preventing it is past; but for practical purposes it is indeed all-important to remember that sanitary administration has its hopes of success in preventing, not in arresting, great epidemics; and that if warnings are not taken from the smaller excesses of disease, catastrophes, not further warnings, may be next to come. It seems almost unnecessary to add that a method of procedure which waits for death as its ground of action may peculiarly dispense with cumulative proofs; and that, as no one preventable death can any longer be remedied in regard of him who has suffered it, so the record of it may the more emphatically claim to be read as a protest on behalf of others.

The vigilance which the Local Government Board has to exercise in regard of the local prevention of disease in England will of course not universally need to express itself in the form of inspections. As regards the Board's giving of advice or assistance to local sanitary authorities and their officers, clearly this would be limited, first, by the fact that, unasked, it could not properly have place except where the local results showed need for it; and secondly, by the consideration, that, in the large and permanent interests of sanitary government, a maximum of local self-reliance and a minimum of central intervention are in themselves important aims. And even as regards mere inquiry into the facts of what is locally going on, correspondence (often bringing in the reports of local officers) will in some cases afford the Board all adequate information for its purpose.

On the other hand, and provided due regard be had to the above considerations, the advantage which may be gained to the sanitary progress of the country by inspections conducted, at least for many years, on a sufficiently large scale, under the Public Health Act, 1858, can hardly, I think, be over-estimated. It has, I believe, been the experience of the Local Government Board in those branches of its administration which do not concern the public health (as particularly in its poor-law and common municipal business) that the personal agency of inspectors of the Board, as distinguished from mere inquiry and advice by letter, is, in a very large proportion of cases, essential to the success of the work: first, in order that the Board may competently understand the local conditions or proceedings which it desires to judge; and secondly, in order that, in a degree and with an effect which no letter-writing can attain, it may make to the local authorities with which it has concern precisely such representations, and may give them precisely such advice, as the particular local circumstances require. The Board would probably not expect experience of a different kind in its future, essentially medical, province of sanitary superintendence; and indeed, as regards this province, my own experience enables me to say with certainty that it is peculiarly one in which clerical, as compared with inspectorial agency, would show itself inadequate to the purpose. By skilled inspections under the Public Health Act, 1858, on such a scale as practically to represent a central audit of local death-accounts, and an exertion of central influence or authority in favour of more active or better-directed local efforts in places where human life had not been sufficiently cared for, the Local Government Board would be in reality, though only in the limited sense which the law prescribes, a Board of Sanitary Superintendence for England.

Briefly then, as regards the Annual Reports to be hereafter made under the Public Health Act, 1858, the state of the case, as I apprehend it, will be this. The Local Government Board will from time to time determine what degree of central vigilance as to the local prevention of disease shall be represented by its proceedings under the Act, and will regulate in accordance with such standard of work the staff by which the work has to be executed. It will be for the holder of my office annually to lay before the Board a report of the proceedings so taken: substantially a report on the new sanitary administration of the country, as examined by the Board from the standpoint of results; and which, so far as means for it exist, would aim at exhibiting, for the information of Parliament, what, year by year, are the chief

existing excesses of disease in the several sanitary divisions of England, and what the relation of such excesses to insufficiencies of law or administration. Incidentally to the above, which I have regarded as the essential business of future annual reports under the Act, it would probably be of advantage to the public service that the reporter should use the same annual opportunity for submitting to the Board, with a view to publication, such new knowledge as the Medical Department might during the past year have acquired with reference to the prevention of disease, and such new memoranda of advice on sanitary subjects as the growing experience of the Department might be held to justify.

From among the many points of local relation which the Board's sanitary superintendence must include, there is one which in conclusion I will specially mention: not indeed without confessing that, in love and honour for my own profession, I regard it with warm personal interest; but believing that I may, nevertheless, without partiality describe it as of fundamental interest to the working of the scheme of recent legislation. While watching, from the point of view of results, the action taken by local authorities throughout England for the better prevention of disease, the Board will be superintending the exact province of work for which the respective local authorities under the Act of 1872 are required to appoint their medical officers of health; and the inspections under the Public Health Act, 1858, will, therefore, so far as they extend, give the Board knowledge of the working of that new institution in the various forms in which it is being tried throughout the country, and in which, in regard of about half the number of cases, the trial is with the Board's part payment and particular responsibility. Such inspections, too, as bringing the Board's Medical Department into direct relation with the local officers of health, and giving the Department opportunity to contribute any assistance in its power to the success of the local institution, will, where they extend, represent an object which the Royal Sanitary Commission, in making the recommendations on which the Public Health Acts of 1871 and 1872 were founded, put forward as an element of their scheme. As regards that intention of the Royal Sanitary Commission, I need hardly say that, to any holder of my office, it must always be among the highest of ambitions to be able to see the experience of this department really conducive to the information and influence of younger fellow-labourers in other parts of the same great field of public service; and it would be affectation in me to deny that, during many early years of the new organisation, relations in that sense between the central and local services may often be of important, and sometimes of indispensable, use to the latter. I would, however, also express my confident expectation that, though from the nature of the case the relation in these earlier years must chiefly consist in assistance which the central office can so render, succeeding years will more and more bring the central office under obligation to local contributors of knowledge, and to local illustrations of progress. And year by year it will surely grow to be among the most useful, as it must also be among the happiest, duties of the annual reporter under the Public Health Act, 1858, to represent, for the information of all the officers of health of the kingdom, such additional fruits of scientific observation, and such new evidences of practical success, as will have come to the Board's knowledge from among their number.

ON BUTTER.—In *Food, Air, and Water* for July there is a paper giving the result of an analysis of butter in Dr. Hassall's Laboratory at Ventnor. In it the curious statement is made that butter contains 'a considerable quantity of butyric acid, which amounts to nearly ten per cent. of the butter-fat.' It is furthermore stated that the insoluble fatty acids in pure butter-fat amount to from 85.48 to 85.71 per cent., whilst the insoluble fatty acids in mutton-fat are 95.6 per cent. Based on these propositions a method of distinguishing between butter-fat and certain other fats is propounded.

[That pure butter-fat contains about ten per cent. of butyric acid is somewhat startling to a chemist. A few weeks ago I had occasion to determine the quantity of butyric acid present in butter, either in the free state or in the form of butyrate of glycerine. From 10 grammes of excellent fresh butter, the history of which I know, after saponification with caustic potash, I could not obtain more than 0.01 gramme of soluble and volatile fatty acids. Instead of 10 per cent. of butyric acid, I got not more than 0.1 per cent.]

Rancid butter appears to yield somewhat more butyric acid than fresh butter; thus from rancid butter I got upwards of 0.5 per cent. of volatile fatty acids. Possibly the small quantity of butyric acid in rancid butter is developed by a kind of fermentation.

The further statement that butter-fat yields only 85 per cent. of insoluble fatty acids whilst mutton-fat yields 95 per cent. is very interesting, if true. It would seem to point to the existence of mono- or di- instead of tri-palmitate of glycerine in butter.

There is, however, a much simpler mode of explanation. Possibly the butter-fat was not quite dry. —*Rep.* J. ALFRED WANKLYN.

REVIEW.

Les Eaux Thermales de l'Île de San Miguel, Açores, Portugal. Lisbon, 1873

Of late years we have heard very little of Portugal in any way, and least of all of its medical resources. We now no longer send patients to Lisbon; and Madeira, which has not recently distinguished itself by readiness to assist our hospitals, is the only Portuguese possession to which a portion of our consumptive patients has remained, (and with very just reason) pretty constant. Yet Portugal abounds in admirable mineral waters; and if the rest of Europe hears of them only through the casual notices of travellers, yet more than two hundred years ago eleven warm and twenty-two cold springs were in use—and one of the queens had established an ample establishment and hospital with accommodation for the poor at Caldas near Obidos.

One of the Azores, that picturesque and prosperous group of islands, best known to us for supplying us with oranges, has long been known to possess thermal waters—for they were described in the middle of the sixteenth century by Dr. Gaspar Fructuoso.

It is extremely creditable to the Civil Governor of the Island of St. Michael, that he has procured a French chemist, M. Fouqué, to analyse the waters carefully, and has printed at length the medical observations of Dr. Philomeno da C. Mello Cabral during several years, thus giving a complete account of the nature and of the medical action of the waters. The

island of San Miguel is like that of Ischia, volcanic, and like it abounds in waters of high temperature, containing soda and common salt. The temperature of its waters is much higher, while the amount of mineral constituents is considerably less than in the case of Ischia. A litre of Caldeira Grande contains 1.818 grammes of solid constituents, chiefly carbonate of soda and chloride of sodium, in nearly equal parts. It is needless to enter further into much detail about waters never likely to be visited by English. But the springs have been divided into—1. The most important ones, containing a large quantity of silica and salts of soda, with a little lime of magnesia, and abundance of carbonic acid; some of these are explosive, and practically geysers; 2. Those containing a little iron; 3. Those containing sulphur; 4. Such as are mixtures of the foregoing with sea water. Weak alkaline waters of high temperature are of use in a great variety of affections, especially in rheumatism and in urinary complaints. These springs are chiefly situated in the Furnas valley, where there is a good hotel and bathing establishment. The island is described as picturesque, containing good hotels, a club, and a theatre.

J. MACPHERSON, M.D.

MISCELLANY.

MUNIFICENT BEQUESTS.—A gentleman of Milan, named Ponti, has left his property, amounting to 825,000 francs (33,000*l.*) to the three Academies of Science in London, Vienna, and Paris, and to the General Hospital in Vienna, the last-named institution being also entitled to any increase beyond the original sum. As the value of the property is now estimated to be 72,000*l.*, the hospital is likely to receive a large share. It is said, however, that the relatives of the deceased intend to oppose the will on the ground of the mental incapacity of the testator.

ÆSCULAPIUS v. BACCHUS.—At the meeting of the American Medical Association, held in Chicago, a series of resolutions deprecating the habitual use of alcoholic drinks were submitted to the meeting, and passed. These resolutions, drawn up by Dr. Horner, are identical in spirit and objection with the declaration proposed by Mr. Ernest Hart two years since, and signed by a large body of the medical practitioners of the United Kingdom. Looking to the great influence exercised by medical men in modern society, in all matters of hygiene and diet, it is gratifying to find opinions of so much moment to the well-being of all classes, spreading from our small island, throughout the continent, and even across the Atlantic.

MEETING OF THE AMERICAN MEDICAL ASSOCIATION. At the meeting of this Association, which took place at Chicago in June last, amongst the papers read were the following. Dr. L. D. Bulkley, of New York, read a paper on 'The Management of Eczema.' Dr. D. J. Farnsworth, of Iowa, read one on 'The Therapeutics of Ammonia,' which was referred back to the author, with a request to publish in some medical journal.

An elaborate paper on 'Mechanism of the Cephalic Circulation,' by Dr. R. A. Vance, of New York, was read, and referred back to the author, with a gracious permission to him to publish it in any journal at his own expense. Dr. F. R. Burcham, of Flint, Michigan, fared better at the hands of his professional brethren. His paper on 'Uræmia,' after a somewhat extended discussion, being referred to the Committee on Publication. Dr. McLaughlin rose in defence of the old-fashioned blood-letting. Forty years ago he had bled freely, and believed he did right. He did bleed now, and thought he was right now as well as then. Men had changed, and were not sick now

in the same way they used to be. He also believed that the same medicine would produce directly opposite effects, according to the dose. Dr. Quimby liked the address because of the happy medium it struck, which was just the thing the profession needed. The tone of the paper on the use of alcohol suited him, it was the most abused of drugs, and the profession are largely responsible for intemperance. Dr. Seguin gave an exhibition of the workings of his system of 'Mathematical Thermometry.' The thanks of the Association were tendered to the doctor, and an outline of his system was ordered to be incorporated in the minutes. In the section of surgery and anatomy, Dr. Dunlap, of Springfield, Ohio, read a paper relative to an operation performed by him in removing a very large tumour from near the sternum. The operation was successfully performed, and the patient survived the operation six weeks. The tumour removed was a very large one, weighing three pounds, and another weighing five pounds was removed after death. Dr. E. M. Moore, of Rochester, read a paper on epiphyseal fracture of the superior extremity of the humerus. In the course of his communication Dr. Moore stated that in these cases reduction is effected by carrying the arm forward and upward to the perpendicular line. Retention is effected by moderate extension while bringing the arm down by the side, maintaining this slight extension until dressings for the purpose of continuing it are applied. Swinburne's method fulfils the indications easily and perfectly. Even if not restored the arm soon becomes useful, and nature gradually rounds off the prominence of the diaphysis and elongates the capsule at the lower border, allowing the motion upward to improve.

HYDROPHOBIA.—New York has lately somewhat severely suffered from this disease. It has proved fatal in five cases; and one sensitive person sank under nervous excitement resulting from fear of it. Dr. Hammond, of New York, asserts that he has made an important discovery in relation to the nature of this malady. He submitted the medulla oblongata of the last victim to microscopic examination, and discovered black spots, which proved to be coagulated blood, near the origin of the spinal accessory nerves and the pneumogastric nerves. Hence it is assumed that hydrophobia is really a nervous disease, and not a blood-poison, as has been generally supposed. Dr. Hammond's attention was directed to the spinal accessory nerves by the symptoms that indicated their operation upon the throat, larynx, and pharynx, in the patient's inability to swallow liquids. The first spasms were in the muscles of the throat. The presence of extravasated blood at the origin of this set of nerves is declared to have proved the accuracy of his supposition. The point of lesion is supposed to have been discovered, and the way to future investigation is plain, granting, of course, the certainty claimed for this discovery of Dr. Hammond, who stands, with Dr. Brown-Séquard, at the head of the medical profession in America upon diseases of the brain and nervous system. From the census returns, it appears that for the last ten years, in the United States, 63 deaths from hydrophobia have taken place. Of these 33 were in the Southern States, 22 in the Northern, 6 in the Western, and 2 in the Eastern. The largest number in one State was 22 in Louisiana. The New York records of the past twenty years show 57 cases, being a pretty uniform rate, hardly increasing as fast as has the population.

WATER-SUPPLY.—The following circular has been addressed by the Board to the several sanitary authorities:—

Local Government Board, Whitehall, S.W.

June 29, 1874.

SIR,—I am directed by the Local Government Board to state that, in consequence of the long continuance of dry weather, their attention has been drawn to the fact that in several parts of the country the ordinary water-supply has become considerably diminished, and there is reason to be apprehensive that, as the summer advances, the evils arising from this cause will be much more seri-

ously and extensively felt. Among such evils must be included the very serious danger to health which will arise if, for want of a better supply, recourse is had to polluted water.

Under these circumstances, the Board think it right to point out to the sanitary authority the importance of taking steps to inform themselves fully of the nature and extent of the existing water-supply in the several parts of their district, and the sources which may properly be relied upon for the purpose of supplying any present or prospective deficiency.

The Board need scarcely remind the sanitary authority that one of the chief duties which the Legislature has imposed upon them is that of providing their district with a sufficient supply of water; and the Board cannot too strongly impress upon them the expediency, at the present time, of adopting every available precaution for the storage of wholesome water in those localities which are likely to suffer from drought.

With this view it is desirable that the sanitary authority should make a careful examination of the existing sources of supply, so that they may, as far as practicable, be economised, and that steps may be taken where necessary to obtain an additional supply.

If any part of the district is within the limits of a water-company, the attention of the company should, with the like object, be directed to the points lastly referred to.

The sanitary authority are aware that if there is no such company, they themselves may not only construct and maintain water-works, but also dig wells, and do any other acts necessary for providing a water-supply for their district.

It is, therefore, competent for them, in case of need, to provide by means of water-carts, or other like expedients, a temporary supply for domestic use, and for flushing sewers and drains; and the cost attendant upon the adoption of this suggestion, which would be comparatively small, might be wholly or in part reimbursed by a moderate charge for the accommodation.

I am directed to add, that the greatest care must of course be taken with regard to the purity of the water which the sanitary authority distributes; that no supply should be used which is not perfectly safe from pollution by excremental matters or other filth; and that other impurities, if the water contains such, should be removed from it by filtration, or otherwise, before it is delivered for domestic use.—I am, sir, your obedient servant,

JOHN LAMBERT, Secretary.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, *Annual Subscription*, 17s. 4d.; *free by post*, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & CO., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & CO.—Calcutta: THACKER, SPINK & CO.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & CO.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & CO., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S.W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, JULY 29, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

BUHL, HERING, AND FRIEDLÄNDER ON PHTHISIS, TUBERCULOSIS, AND INFLAMMATIONS OF THE LUNG.*

(Continued from page 450.)

Miliary tubercles may supervene on the varied forms of phthisis described above, and are then due to absorption (resorption). Buhl indeed holds strongly to his earlier views of the specific nature of the cheesy material, which, in an overwhelming number of cases, leads to infection—for amongst 300 cases of miliary tuberculosis only 10 per cent. were found without a cheesy focus; that is, he still holds them generally true, but now approximates his theories more to those of his reviewer, since he admits that the absorbed material, which leads to the production of tubercles, need not necessarily be derived from a cheesy deposit, but may be derived 'from retrograde metamorphosis, which may be generated, distributed, and developed by altered conditions of general nutrition' (p. 119). The concession Buhl is inclined to make (in this second edition) that the *materia peccans* may consist of formed (corpuscular) elements; but in the sense that they may be bacteria, derived from the cheesy foci by means of the circulation of blood and lymph, his reviewer is disinclined to accept. Too much is already ascribed to bacteria to make us willing to still further complicate the vexed questions of tuberculosis by introducing these organisms. Waldenburg holds the opinion, which has been forced upon him by experiments, that miliary tubercles result from the absorption of formed elements, and not from absorption of an unformed contagion dissolved in the blood-plasma, or other juices (*Säftmasse*). It seems to him easier to admit that a great number of solitary finely divided foreign bodies may cause a great number of isolated centres or foci of disease (miliary tubercles), than to understand why fluid or volatile matters uniformly disseminated in the blood-plasma should pro-

duce a great number of isolated tubercular deposits. Buhl, and all who have worked at this subject, consider this essential; and they further distinguish between local infection through contiguity, which probably takes place through the lymphatics and extravascular channels (*Säftcanäle*), and the general infection due to blood-vessels. He gives the name of *Phthisis combinata*, first proposed by his critic, Waldenburg, to this supervention of tubercles on caseous pneumonia. For absorption and infection to be possible, the cheesy deposits must be imperfectly encysted. Miliary tuberculosis has its seat in the connective tissue of the lymphatic vessels: it is a lymphoma in Virchow's sense of the word. Giant-cells are not peculiar to tubercles, and are not even constant elements of these, although for the most part, at least at early periods, they will be found in them. Besides secondary inflammations producing tubercles, by means of setting up cheesy deposits, Buhl admits a specific 'tubercular inflammation' one which not merely accidentally, but necessarily and peculiarly carries with it the production of tubercular lymphomata (deposits of miliary tubercles) simultaneously with the inflammation; these, however, are strictly limited to the inflamed tissues affected. Caseous pneumonia, tubercular pleuritis, pericarditis, peritonitis, and meningitis, give rise to such tuberculous inflammation. Waldenburg suggests that this might as well be called 'inflammation with formation of tubercles,' since Buhl and every one else admit the primary inflammatory type; and the tubercles appear to be secondary to this, whilst the true causes are yet unknown, or controverted. Waldenburg thinks, and the translator believes rightly, that Buhl draws somewhat too sharp lines of demarcation between lobar and lobular, superficial and parenchymatous inflammation. Nature is less arbitrary, and in practice the diagnosis is often an impossibility, for lobar and lobular inflammations are frequently combined in the various forms of phthisis. Nor does he approve much more of the innocent-looking distinction between superficial and parenchymatous inflammations. We all make it, but not in the same sense as Buhl, who scarcely allows any transitional forms. His chief merit, we think, is that he has established the parenchymatous nature of the inflammations which set up phthisis (the collective name of 'parenchymatous pneumonias' would seem most applicable), and has separated desquamative pneumonias from simple catarrhal ones, with which they were previously confounded. (Reinhardt's gelatinous pneumonia [A.D. 1850] corresponds very nearly to Buhl's desquamative pneumonia.) This, we think, will be a permanent gain, though the theories Buhl appends to the facts may be displaced. Buhl considers all secretions found in the air-cells as secondary; consisting for the most part of desquamated epithelium which has grown wildly, though he admits that inspissated pus, sucked in from the inflamed bronchi, may also be found there. He totally denies Virchow's views of a primary bronchitis, with catarrhal pneumonia, leading to a secondary parenchymatous inflammation of the bronchi and air-cells through accumulation and metamorphosis of the secretions; though he admits that foreign bodies from without (dust, particles of grit, etc.), may set up parenchymatous changes. Waldenburg thinks the lessons of general pathology teach us otherwise. This is the real battle-ground as to Buhl's doctrines. We must sever fact from theory. It is a fact that the parenchyma

* Inflammations of the Lung, Tuberculosis, and Consumption.—'Lungenentzündung, Tuberculose, und Schwindsucht,' 12 Briefe an einen Freund. Von Professor Dr. Ludwig Buhl; 2 verbesserte Aufl. München. 1873: Rudolf Oldenbourg. 8vo, 169 pp.

Experimental and Microscopic Researches on Tuberculosis.—'Histologische und experimentale Studien über die Tuberculose.' Von Dr. Theodor Hering in Warschau. Mit 6 lithographirten Tafeln. Berlin: 1873. Hirschwald. 8vo, 112 pp.

Clinical Studies of Pulmonary Inflammations, with remarks on the Normal Epithelium of the Lungs.—'Untersuchungen über Lungenentzündung nebst Bemerkungen über das normale Lungen epithel.' Von Dr. Carl Friedländer. Berlin: 1873. Hirschwald.

On Localised Tuberculosis.—'Ueber locale Tuberculose.' Von Dr. C. Friedländer. Volkmann's *Sammlung*, no. 64. Leipzig: 1873.

of the lungs and bronchi are implicated in phthisis; it is theory that this inflammation is always a primary affection, and never secondary. Buhl believes that the sputa afford proofs of the correctness of his theory. He states that the sputa of desquamative pneumonia, *i.e.*, the primary stage of most forms of phthisis, are highly characteristic and even pathognomonic. They do not consist, we are told, of viscid pus, but are distinguished by the presence of a great quantity of alveolar endothelium (epithelium of the air-cells) with growing nuclei, with exudation-corpuscles (granule-cells), free fat-granules, and ciliated cells (*Flimmerzellen*) to which by and by deeply pigmented cells are added, and as the disease goes on, a gradually increasing myeline degeneration. From the mass of myeline cells, and of free myeline, the duration of the disease may be approximatively estimated. This description is so novel, and so contradictory to our present views, that it needs further confirmation. Hitherto the sputa have been known to contain some normal, and some fattily degenerated mucus and pus corpuscles, with free fat-granules; and at a later date, elastic fibres, sometimes myeline also, though this has not been considered peculiar or specific; and, as in other sputa, other epithelium also. But to find sputa consisting wholly, or even in great part of alveolar endothelium, in various stages, is so novel that medical men ought to direct special attention to this point. Buhl also insists upon the pigment being formed from the blood-colouring, whilst modern researches seem to indicate its origin from without. Buhl omits to say if his lardaceous degeneration gave the chemical reactions of amyloid material. His statement that glands in the horse is fully developed tuberculosis, is certainly as yet quite unsupported by facts. Buhl confirms Waldenburg's opinion, founded on a long series of cases, that a primary laryngeal affection often precedes pulmonary phthisis, which is secondary to the throat mischief. The primary affection he has observed consists in perichondritis of the larynx; and, according to Buhl, this is an analogous process to peribronchitis.

Hering's work is of great value, though not much noticed as yet. All experimenters who do not wish to tread in beaten paths should study his pamphlet. Hering's investigations were partly experimental, partly microscopic. A series of eighty-two inoculations of tubercles and cheesy material, partly fresh, partly preserved in spirits, and lastly of a variety of materials (*indifferenten Stoffen*), led to practically the same results, as the reviewer had previously maintained. Hence it follows that a true milary tuberculosis, exactly corresponding to the human disease, may be produced in rabbits and guinea-pigs, not only by the inoculation of tubercles, but also of other materials, especially non-tuberculous pus; and hence that tuberculosis cannot be regarded as a specific disease. Six experiments introducing tubercles into the stomach of animals gave negative results. Hering has made several fresh points, especially as to giant-cells. He found these, like other observers, not only in human milary tubercles, but also in those produced in animals by inoculation; but in neither one nor the other were giant-cells constant elements. Hence they can scarcely be considered to have a special significance. Further, Hering has demonstrated giant-cells in tissues which were certainly not tuberculous. Besides generally admitted facts, he found them in a case of neuroma fibrillare of the optic nerve. In the course of his

researches, Hering formed the opinion that the so-called giant-cells of tubercle and of analogous formations correspond in all probability to sections of lymphatic vessels. The finely granular matter which fills them up he takes for the coagulated contents of the lymph-vessel, their embedded cells for endothelium, their forms being altered by luxuriant growth. This, though hypothetical, deserves careful attention. These uncanny (*ungeheurig*) cells with a hundred or more nuclei are foreign to all our common notions of cells, and anything which would take them out of this category is attractive. Histologists ought seriously to grapple with this question.

Hering distinguishes two forms of milary tubercle: the first, or endothelial tubercle, consisting of elements which may be directly attributed to increased production (*Wucherung*) of the endothelium or perithelium of the subadventitial vascular spaces (Rindfleisch's *Pathology*, vol. ii. p. 299, Dr. Baxter's translation); the second form, or reticulated tubercle, containing a network with giant-cells. But, as he considers the latter to be sections of lymphatics with increased endothelium, he is forced to admit a combination of both forms; that both must be considered as true tubercles, and have this in common, 'that in both, the endothelioid cells are of chief histologic importance, and irritation of these appears to be the starting-point of the circumscribed nodules.' Hering is specially inclined to trace back tuberculosis to irritation (*Reizung*). Both forms of tubercles 'must be considered as only circumscribed milary foci produced by formative or plastic inflammation.' The first form is most commonly found on the surface of serous membranes, and seems to be directly due to preceding inflammatory processes, without any extraneous focus of infection being apparent. Hering, like others, considers 'tuberculous inflammation' to be a proper name for this variety. For the second or reticular form, which occurs in various organs of the body, after certain previous inflammatory processes, we can, in the vast majority of cases, demonstrate infection from cheesy deposits.

Hering's investigations make him believe that in the so-called 'acute milary tuberculosis of the lungs,' the little nodules which occur are not generally true tubercles, but recent, disseminated, and circumscribed pneumonic foci. The microscope alone can distinguish these from true tubercles also occurring in the lungs. The so-called tuberculous ulcers in the larynx and bowel, Hering, in common with his critic and others, believes to originate, not in softened tubercles, but in inflammatory affections of the mucous membrane and its follicles, with which a secondary milary tuberculosis in contiguous parts may [by infection?] associate itself.

Hering at least has one great merit—he is thoroughly familiar with all that has been done beforehand in this vast subject.

ON INJURIES TO THE EYE IN THEIR MEDICO-LEGAL RELATIONS. BY PROFESSOR ARLT, OF VIENNA.*

(Continued from page 290.)

II.—WOUNDS OF THE EYE, IN WHICH A FOREIGN BODY IS NOT LEFT IN THE ORGAN.

19. Wounds of the *Conjunctiva* are generally easily recognised if they do not affect the transition-

* *Wiener Medizinischer Wochenschrift* May 23.

part (*Uebergangstheil*), and do not acquire a high importance.

The first indications of the injury are hæmorrhage, ecchymosis and swelling of the edges, and much gaping of the wound. Subsequently, after marked retraction or actual loss of substance, the surface of the wound becomes covered with a light grey layer, under which granulations are developed, which either bring about union of the edges, or become more or less elevated and then gradually narrowed at the base, becoming at last attached only by a narrow pedicle. They may be easily cut away with scissors; but, if they have a broad attachment, must be frequently touched with nitrate of silver. The resulting cicatrix may be imperceptible, linear, or radiated; in the latter case, it is firmly adherent to the sclerotic. It is only when the loss of substance has been great, and a large quantity of the neighbouring conjunctiva has been drawn in for the purpose of filling it, that the movements of the eye and the escape of the tears are impeded.

When the wound implicates the conjunctiva palpebrarum and also the opposite conjunctiva bulbi, care must be taken to prevent symblepharon. The application of a suture is no longer dreaded, but is employed with advantage.

20. *Wounds of the Conjunctiva with Perforation of the Recti Muscles* (partially or entirely), the diagnosis of which can scarcely be difficult, may have as their results slight impediment of the free movements of the eye, and secondary deviation of the organ with double vision.

In recent cases, we may attempt to avert these results by the application of a deep suture; in a later stage, when the muscle has contracted adhesion far back to the sclerotic or the tunica vaginalis, relief may then be expected from separation and suture.

21. *Wounds of the Conjunctiva, with Penetrating Wound of the Sclerotic*, acquire from the latter a high importance, in so far as the ciliary body is implicated or more or less of the vitreous humour escapes (see sec. 4, p. 240).

Recent penetrating wounds of the sclerotic are characterised by diminished tension of the globe, and by the appearance of elements of the uvea (especially pregnant) on the extruded vitreous substance. The cicatrices show fixing of the conjunctiva, pigmentation, and radiating contraction; if very small, they may altogether escape notice. The prognosis in large wounds of the sclerotic may be rendered unfavourable by abundant loss of vitreous humour, or severe intraocular hæmorrhage. In other cases, through consecutive inflammation, destruction not only of the injured but of the sound eye is threatened. There are also cases, especially of deeply penetrating wounds of the sclerotic, in which, after cicatrisation has apparently taken place favourably, retraction (more or less evident, frequently funnel-shaped) of the sclerotic takes place, the field of vision becomes limited, and total blindness at last sets in.

Hence no definite opinion can be formed as to the result of a penetrating wound of the sclerotic extending into or near the retina, till several months have passed without any untoward result being observed, especially retraction of the sclerotic. The plan of suture of long wounds of the sclerotic, followed by Windsor, Bowman, Lawson and Poley, may be regarded as an improvement in the treatment, if it can be employed without further loss of vitreous humour. Without it, long continued rest and the careful application of a protective bandage are necessary.

22. *Wounds of the Cornea* and their immediate results are sometimes very slight, sometimes severe, and are only to be recognised by special methods of examination.

When the image of a window (not too near) on the cornea is viewed from different points, the position of the cornea relatively to the window and the observer being changed, the slightest depression or elevation of the surface of the cornea may be readily perceived. Little vesicles of mucus, like soap-bubbles, which are produced from the oily secretion of the Meibomian follicles, and from the lacrymal fluid, may be readily distinguished from persistent elevations by their mobility and instability.

If the light of a candle be allowed to fall in a dark room through a convex lens of one or two inches' focal distance, held about a foot from the candle, in such a position that the axis of the lens coincides with the straight line connecting the cornea and the flame, there will be seen a light disk on the surface of the eye, the intensity of the illumination of which increases as the glass is removed further from the cornea; and any opaque spot on the cornea, which would be overlooked by the naked eye, is rendered visible as the lens is moved either back, or from side to side. Since the introduction of this method by Helmholtz, it has become known that the most minute penetrating wounds of the cornea (as in keratonyxis for dissection of the capsule) do not heal without leaving some opacity, and that opacity follows loss of the corneal substance in cases where hitherto the cornea has been thought to be transparent.

In examining recent wounds of the cornea, it is before all things necessary to determine whether the wall of the globe (the cornea or the adjoining portion of the sclerotic) be penetrated or not.

Perforation is indicated by raising or diminished depth of the anterior chamber, with diminished tension of the eye, the apposition of a portion of iris to the wound, drawing up the pupil towards the wound, pressure forward of the iris or (in wounds at the corneo-scleral position) of the vitreous body. Union between the anterior and posterior walls of the chamber, as well as the presence of small portions of pigment from the iris on the cornea, readily indicates that perforation has occurred at some previous time. They are generally only observable by focal illumination. Blood in the anterior chamber may arise from wound of the iris, or from bursting of the uveal vessels through compression of the bulb at the same time with the infliction of the wound. If the instrument have passed through the anterior capsule beyond the pupil, opacity of the lens may be observed in a few hours; if it have come into contact with the iris, it may leave in this a rent or hole, or a clot of blood.

Later, when inflammatory action has set in, especially with suppuration and more or less surrounding opacity, the questions as to the duration, form, and depth of the wound can no longer be answered; and it may remain uncertain whether the injury has been produced by the penetration of the injuring body into the eye, or by contusion through sudden pressure.

Wounds which directly or after suppuration leave only a superficial perforation or superficial loss of substance (extending not so far as Descemet's membrane), may heal without leaving permanent opacity. If the loss of substance extend deeply, or if the individual be advanced in years, or have lost flesh, opacity may be expected; and it destroys the function of the eye generally more by the diffusion of the

light and illumination of the entire retina, than by arrest of the rays of light which should fall from the object on the retina.

Denudation of the corneal nerves (through superficial loss of substance), generally gives rise to severe and continued pain; while their division even in extensive wounds, or in the extraction of cataract, appears to be less painful.

Excavation or abrasion of the cornea, affecting not only the epithelium but the superficial fibrous layer (Bowman's membrane), I have observed to follow only injuries with such articles as a comb or a finger-nail; but I have no doubt that it may occur as the result of a fight. The severe pain from denudation of the corneal nerves, the disturbance of vision, the pericorneal injection, the spasmodic contraction of the lids, photophobia, and lacrymation, generally subside in a few days under the operation of cold compresses; but I have in these cases noticed the recurrence of the symptoms some weeks after apparent recovery, and indeed they have recurred three or four times for a day at intervals varying from four to eight weeks. Such later attacks may be regarded as neuralgic if the pain present a certain type; but, on careful examination of all parts of the cornea with the speculum, some excoriation is found, and on questioning the patient it is found for the first time that an injury, perhaps scarcely noticed, has taken place. A woman from the neighbourhood of Krems came to me complaining of pain in the eye, which had returned for the fourth time and lasted eight or ten days. On being questioned closely, she remembered that her child had struck her eye with a needle about half-a-year previously.

The disorder may be easily removed permanently by keeping a protective bandage applied day and night, and dropping atropia daily into the eye. This treatment must be continued on an average from eight to fourteen days.

(To be continued.)

SIMON ON PELIKAN'S OBSERVATIONS ON THE DIFFUSION OF ASIATIC CHOLERA IN EUROPE,

Mr. John Simon, in the following letter to the president of the Local Government Board, discusses the observations of Dr. Pelikan, director of the Medical Department of the Russian Government, on Mr. J. Netten Radcliffe's Memorandum on the Recent Discussion of Cholera in Europe.

Two years ago, when continental Europe had recently been suffering afresh under a very extensive diffusion of Asiatic cholera, and when the infection of the disease was still continuing (as indeed I may add it has even till the present time continued) to show its presence on the Continent, I brought under Mr. Stansfield's notice a report which had been addressed to me, May 7, 1872, by Mr. John Netten Radcliffe, one of the Board's medical inspectors, giving all particulars which we had then learnt with regard to this new manifestation of epidemic cholera in Europe, and suggesting that possibly the diffusion had started from a new infection brought to Kiev from Northern Persia, by way, first, of the Transcaucasian land-route from the Caspian, and then by Black Sea steam-navigation to South Russia.

Whether the particular diffusion of cholera which gave occasion to Mr. Radcliffe's report did or did not arise from the source which the report suggested

as possible, at least Mr. Radcliffe's argument as to the readiness with which the Transcaucasian route in its new development might facilitate the access of Asiatic cholera to Europe, seemed to me likely to be of general interest to sanitary administrators throughout Europe; and, on my submitting this to Mr. Stansfield, he was pleased to direct that the report should be brought under Lord Granville's notice with a view to its being communicated by the Foreign Office to other European Governments.

This course having been taken under Lord Granville's direction, a communication of great interest was received in reply from the Russian Government, giving the observations of Dr. Pelikan, the director of the Medical Department of that Government, on the papers which had reached him from this country. Dr. Pelikan's observations, with a memorandum which Mr. Radcliffe has written on them, are now put before you in print, as material to which reference may probably be made in the Conference about to be held at Vienna on the subject of our European defences against cholera.

The papers, Russian and English, have in the main a common basis of opinion as to cholera. They have had no occasion to touch the still disputed question of the process or processes by which cholera maintains and spreads itself in its own native climate of India: and, on the other hand, as regards the means by which it is spread beyond those limits (ordinary and extraordinary) of its endemic prevalence, educated medical opinions vary comparatively little. No competent person pretends that the power of human intercourse to give pandemic extension to cholera is irrespective of most important qualifications in regard of both place and time; but that, subject to these qualifications, human intercourse is the essential agent of such extension is the conclusion which almost all modern opinions now recognise, and in which (as might of course be expected) Russian opinion and our own are apparently in full accord.

The peculiar interest of Dr. Pelikan's observations centres in the evidence which they supply as to the now seemingly persistent presence of Asiatic cholera in Eastern Europe. That this has at least for the last nine years unquestionably been the case, we are able, with the aid of Dr. Pelikan's information, clearly to see; and Dr. Pelikan explains the fact, not as betokening successive re-infections of Europe from Asia, but as being simply the continuance of one infection. He supposes that the Asiatic infection, when once introduced into Europe, or at least into certain parts of Europe, can acclimatise itself here, with latent powers of epidemic increase, for indefinite periods of time; and, in illustration of this view, he, besides adducing the more recent Russian experiences, communicates a very interesting memoir by Dr. Arkhangelski (of which a translation is appended) on the distribution of cholera in Eastern Europe during the decennium which followed 1846. On the showing of Dr. Arkhangelski, the severe epidemic which invaded England in 1853-54 was no result of new infection from Asia, but was mere reverberation, from Eastern Europe, of the infection which had been with us four years before; and similarly, according to Dr. Pelikan, the fact, that for the last three years we have been under constant threat of a new choleraic invasion, means only that Eastern Europe has for this long while retained, and is from time to time rekindling to new acts of devastation, certain unextinguished embers of the great epidemic of 1865.

The facts which thus come under consideration are of striking prognosticative interest. They represent the choleraic infection as becoming for European Russia, and probably tending to become for all Europe, an influence scarcely to be called alien and rare, but at least comparatively naturalised and habitual : gradually assimilating itself in this respect (as we have long known it to be akin in certain other respects) to the familiar European bowel-infection of typhoid fever. And the importance of the facts in this point of view seems to me to attach to them equally, whether they be explained on one supposition of their origin or the other,—whether they arise, as Mr. Radcliffe's former argument would suggest, by means of repeated introductions of new infection from without, or, as Dr. Pelikan maintains, by the long persistence in vigour of each one infection that is introduced. On either supposition we have to remember, with regard to the future, the increasing facilities for infection from India which are inseparable from the developments of traffic. Thus, if it be true (as Mr. Radcliffe suggested) that unnoticed re-introductions of infection from Asia in 1852 and 1869, following close on the then previous infections, gave a fallacious semblance of continuation to epidemics which otherwise would have been evidently at an end, is it not likely that the number of such unnoticed re-introductions, one following so close on the other as to produce continuity of effect, will multiply in proportion as our constantly increasing and constantly accelerating traffic from the East gives multiplied opportunities for their occurrence? And if, on the contrary, it be true (as Dr. Pelikan believes) that the one infective wave of 1846 did without reinforcement cause ten years of cholera in Europe, and that again the one infective wave of 1865 has without reinforcement caused consequences which are not even yet brought to an end, is it not certain that the permanence of cholera in Europe can be maintained by far fewer new infections than the conditions of our present and future traffic with Asia are sure to bring with them?

If, then, Eastern Europe must in effect for the present be regarded as ordinarily containing foci of epidemic cholera, from which the infection, when favoured by season, can almost without warning spread itself, not alone in Eastern Europe, but along scores of lines of communication, by land and water, in the whole European area, and if we must accept, as but too probable, that this state of things may gradually tend, by force of circumstances to realise itself on a far larger scale than the present, the prospect evidently is one which needs to be faced and fully considered. Civilised human life has already a hard struggle against the chief contagia which hitherto are current in Western Europe—against small-pox and typhus and scarlatina and typhoid and diphtheria and measles and hooping-cough; and the possibility of a new and most deadly contagium tending by degrees to become similarly current here can hardly be contemplated without a first feeling of dismay. Also, it must, I believe, be recognised that from the one direction to which our forefathers would, in circumstances like the present, have fondly looked for safety, little reasonable hope can come to us. The passage which Mr. Radcliffe quotes on the subject of quarantine from my eighth Annual Report to the Privy Council, represents convictions which I still strongly entertain, and which for many years past have been at the root of all advice which I have had the honour

of submitting to Her Majesty's Government, in regard of the foreign sanitary relations of this country. I believe that it fairly applies to the whole of the case which I am bringing before you. Against re-importations of the Asiatic infection into Eastern Europe, I cannot imagine that Russia and Turkey will, by quarantine, make in the future more successful resistance than they have made in the past : against cholera already localised in Eastern Europe, it seems to me singularly improbable that any commercially active part of the continental area should effectively protect itself by quarantine; and against cholera current on the continent of Europe, England (as I have endeavoured to show in the argument which Mr. Radcliffe quotes) can assuredly not so protect itself.

The nature of the defences which we in England have at our disposal against cholera when brought into our ports, may be gathered from two papers which are appended to my recent annual report : one, the order which the Local Government Board has in force with respect to ships suspected of choleraic infection; the other a memorandum of advice to the public on the mode of propagation of cholera. Under the order each port sanitary authority has certain facilities for inspecting ships of suspicious arrival, and can deal, as regards things and persons, with cases of manifest or probable choleraic infection, by requiring the disinfection or destruction of infected or probably infected things, and, if it has hospital accommodation, by requiring that no person with manifest or probable signs of cholera shall leave the ship except for treatment in hospital : these facilities and powers being in substance such, and only such, as the port authority also possesses in relation to small-pox and typhus, and other of our accustomed infections : but of quarantine strictly so called—that is, of detaining for periods of sanitary observation persons who do not already appear sick, the order has nothing to say. It tacitly confesses that England has abandoned as futile, and as tending to inspire false confidence, such quarantine or pretence of quarantine as is alone possible to a great commercial community; and that when cholera is current on the continent of Europe, we must accept, as practically not to be avoided, innumerable chances, which indeed make certainties, that the same contagium will freely enter our own country. It is on that basis that the true defences of England against cholera have to be planned; defences, not peculiar to the coast-line of England, but, in principle, equally to be aimed at in each sanitary district throughout the country; defences, which (as explained in the memorandum above referred to) consist essentially in those common hygienic precautions which local sanitary authorities are responsible for providing or enforcing, and, above all, in extreme vigilance in regard of the local supplies of water and the local prevention of filth. Thus, in truth, the increasing influence of cholera on the continent of Europe is chiefly to be regarded in this country as an additional appeal to our fifteen hundred local authorities to move swiftly and effectively in duties which already, on other grounds, are urgently incumbent on them. 'The local conditions which would enable cholera, if imported, to spread its infection in this country, are conditions which day by day, in the absence of cholera, create and spread other diseases : diseases which, as being never absent from the country, are, in the long run, far more destructive than cholera : and the sanitary improvements

which would justify a sense of security against any apprehended importation of cholera would, to their extent, though cholera should never reappear in England, give amply remunerative results in the prevention of those other diseases.' Above all, in the sense of preventive medicine, I would refer to the close etiological affinity, at least in Europe, between the diffusion of cholera and the diffusion of typhoid fever; I would advert to the hope, which surely recent legislation justifies, that our local authorities will proceed with swift and sure steps to extinguish the latter filth-disease within their respective areas of jurisdiction; and I would venture to express a belief, which is among the strongest convictions of this department, that, in proportion as common sanitary improvement takes from typhoid fever its present deplorable and disgraceful power of spreading among our population, in such proportion will England have better security against cholera than any imaginable system of quarantine could have given her, and will be able to receive with comparative impunity whatever importations of cholera-contagium may thenceforth accrue to her from abroad.

If the opinions here expressed be well founded, they can scarcely be deemed applicable to England alone. If it be (as I think it is) next to impossible that the access of the cholera-contagium to Europe, or its dissemination over the European area, should ever be prevented by quarantine, surely by common consent the object which must be deemed of first importance is to have removed, wherever the contagium may be expected to reach, those local conditions on which it depends for its powers of propagation. I observe with particular pleasure and hopefulness the emphasis with which Dr. Pelikan applies this principle—if not exactly in our English sense, yet at least in a sense which must eventually be of good result, to the present continuance of cholera in Eastern Europe. From our English point of view it seems little less than certain that, along the whole succession of lands which receive (whether to transmit or to retain) the streams of westward traffic from India, common hygienic vigilance in the respects to which I have above adverted might be of immense human interest as preventing the diffusion of cholera: of interest first to each district for itself, but also through it of interest to all. Of the sanitary circumstances of other countries than our own I can speak only as a reader or casual visitant; but, even with this slender information, I think I can plainly see that the familiar local causes of typhoid fever lie broadcast along and about the lines by which commerce travels from east to west, and represent what English medicine would consider unbounded facilities for the spread of choleraic infection. To influences which may thus be exerted on Europe at various times by the sanitary unculture of Persia and Irak-Arabi, of the lands which border the Red Sea, or of Mediterranean and Euxine Turkey, it is unnecessary in connection with the present papers to refer; but with reference to the vast analogous interest which Continental Europe has in its own hygienic progress, I may observe that the facts which Dr. Pelikan brings to our knowledge seem to me singularly suggestive. Whether it have been by re-infection or by continuance of infection that Eastern Europe has been able to provide during so many years an habitual lodgment and breeding-place for cholera, equally I would concur with our eminent Russian fellow-worker in urging that thorough investigation should be made of the

local circumstances under which that sad susceptibility to the infection exists; and, from the standpoint of our English experience, I may venture to express a somewhat sanguine hope that in such investigation the essential determining causes of the evil will prove to have consisted in Eastern Europe, as certainly the like have seemed to consist in England, of only such defects of local sanitary administration as admit easy and permanent removal.

LECTURE.

LECTURE UPON GENERAL THERAPEUTICS OF THE NERVOUS SYSTEM. By E. C. SEGUIN, M.D.

(Continued from page 414.)

CLASS B.

Means which affect the Substance of the Nervous Centres (continued).

2. Depressants and anæsthetics are thus divided.

- | | |
|---------------------------|---|
| (A)—Cerebral depressants. | { Cold, bromides of potassium and calcium, opium, hydrate of chloral, food, &c., chloroform, ether, &c. |
| (B)—Spinal depressants. | { Conium, bromide of potassium, cold, and food. |

A. CEREBRAL DEPRESSANTS.—Cold is to be employed in the same manner as when we wish to produce an anæmic condition of the brain. The inclination to sleep experienced by persons exposed to severe cold, such as encountered in the arctic regions, is an illustration of the effect which cold can produce upon the nervous system.

The India-rubber bag sometimes employed in making applications of ice diminishes the intensity of cold applied, and is inferior to the bladder ordinarily employed (*vide supra*).

Bromide of potassium has usually been spoken of as acting through the blood-vessels, and causing their contraction, and consequently anæmia of the parts they supply. Dr. W. A. Hammond and many others speak of the remedy as acting in this manner. There has been some doubt expressed as to whether bromide of potassium is a true hypnotic. At present, perhaps, this is to be regarded as an unsettled question. For my own part, judging from my own experience and the testimony of others regarding bromide of potassium, I have been led to conclude that, when given in sufficient doses, it acts very powerfully as a cerebral depressant. In health, I admit that no narcotic effects are obtained from a few doses of the medicine; but, in cases of cerebral irritation, and insomnia from a variety of causes, its action is sure and immediate. In delirium tremens, for example, in such cases as are not complicated by degenerative liver and kidney disease, in the so-called sthenic cases, bromide of potassium, given in doses of \mathfrak{zj} or more every hour, until $\mathfrak{z}\text{ij}$ or $\mathfrak{z}\text{iv}$ have been taken, will, conjointly with semi-darkness and quiet, cut the attack short by producing sleep. In 1866-67, while house-physician to the New York Hospital, I had the opportunity of thus treating a series of these cases with very satisfactory result. I say this, while perfectly aware that several medicines seem to shorten the duration of delirium tremens, and that it is, under certain conditions, a self-limited disease.

In certain forms of insomnia seen in connection

with fevers, the bromide of potassium may fail to produce sleep, because (?) of the continued influence of a blood-poison in keeping up the morbid state.

In the insomnia and delirium of pneumonia I have also seen speedy relief procured by \mathfrak{v} ij or \mathfrak{z} j doses of bromide of potassium. In the simpler (?) conditions of sleeplessness caused by anxiety, over-exercise of the brain-functions, emotional disturbance, this remedy usually acts well. Perhaps the most convincing proof of the action of bromide of potassium upon the cerebrum is to be had from observing the effects of the long-continued use of large doses of the remedy. A condition called 'bromism' is set up, characterised by stupor, deficient memory, aphasic-form speech, tottering gait, loss of facial expression, salivation, mucous irritation, papular skin-disease, &c. Although we see this result more often in the course of the treatment of epilepsy, yet it may be developed in persons not having this disease. The mental state of bromised persons is not unlike that of patients with dementia.

Hydrate of chloral is, in my opinion, the best medicine that can be employed for producing sleep. It does not intoxicate or disturb the digestive organs, as opium does. When chloral succeeds—and it almost invariably does succeed—it produces a calm sleep, not followed by any special disturbance of the system. I would have you bear in mind that this remedy is a much more direct hypnotic than opium, and yet that it does not possess the power of preventing the perception of pain. Hence a rule to follow is to give chloral in cases of insomnia not connected with pain. The physicians to insane asylums in Europe and in this country have found in chloral an invaluable agent for giving rest to patients suffering under mania in any of its forms. They have also testified to the very great safety attending the use of the medicine, many patients getting large doses of it nightly for months and years. Chloral may also be used in the cases where (*vide supra*) bromide of potassium is indicated, and the two may be given together. If you are to choose between these two drugs, use bromide of potassium, if in addition to the cerebral irritation there exists some physical excitement (spinal irritation); chloral in cases of pure cerebral disturbance. The theoretical view, that bromide of potassium acts by causing anæmia of the brain, leads to the withholding it in cases of cerebral anæmia and malnutrition. This I believe to be an error, since in my experience the occasional giving of bromide of potassium (and chloral hydrate) in such cases has in no way hindered the good effects of restorative medicines.

The dose of hydrate of chloral may be, for adults, \mathfrak{v} gr. or \mathfrak{z} j. In females, especially, it is well to try a small dose on your first trial. A scruple dose I believe to be a perfectly safe one for a man. The doses of \mathfrak{v} ij and \mathfrak{z} j should be used in cases of acute mania, or severe delirium.

The conjoint use of bromide of potassium and chloral is very satisfactory. A drachm of bromide of potassium may be administered in the afternoon, followed at bedtime by grs. xx. or xl. of chloral.

Concerning the use of opium and its constituents in diseases of the nervous system I believe that I need say very little. I would have you always bear in mind the exceedingly unpleasant way in which this remedy affects very many females, producing insomnia and, later, vomiting and constipation. For these susceptible individuals (a few males must be included) some of the liquid compound preparations

of opium, McMunn's elixir, the liquor opii compositus, may be substituted for morphia or simple opium. In a very large number of cases of nervous disease we seek to relieve pain by the use of morphia. In such cases it is best administered hypodermically, in the form of strong solution of the sulphate, or acetate, or muriate. I must admit that my own patients seldom receive any but the sulphate of morphia injections, in the shape of Magendie's solution (16 gr. to \mathfrak{z} j), \mathfrak{m} x of which are equivalent to one-third of a grain of sulphate of morphia. I am, however, in the habit of adding a little atropia, $\frac{1}{100}$ or $\frac{1}{50}$ gr. to each hypodermic injection, for the purpose of remedying the nauseating and constipating effects of the morphia. My solution of atropia is composed of atropia gr. j, distilled water \mathfrak{z} v: \mathfrak{m} j, containing $\frac{1}{300}$ of a grain of atropia. I have employed this combination since 1867 with great satisfaction.

Food is a depressant, because it remedies the morbid irritability produced in the brain in cases of exhaustion, whether from hæmorrhage or over-work. Sometimes the effect of food is very marked indeed. Many of you have doubtless experienced a sensation of exhaustion, accompanied by headache, perhaps severe, which has been entirely relieved by taking a good meal. The headache perhaps has been made to disappear even before the meal was completed, and you have felt immediately refreshed, and that without wine or other alcoholic stimulant. In many cases of delirium and mania, the effects of the persistent giving of nutritious food are evidenced by rapid improvement and cure.

B. SPINAL DEPRESSANTS.—Conium is the type medicine of this class, and seems to be the direct antagonistic of strychnia. It acts by paralysing the spinal motor centres, from the nucleus of the third nerve down. This remedy can be used with benefit in spasmodic affections. In small doses it produces a paretic condition of the spinal axis, indicated by partial ptosis, strabismus, or double vision, and weakness of the knees; and the arms may become slightly paretic. The symptoms appear within an hour after the medicine has been taken. By the administration of larger doses almost complete akinesis is obtained, which may last for half an hour or an hour, but is not dangerous. The remedy should be given only once a day, and in many cases to the extent of partially paralysing the patient. A reliable preparation is the English *succus conii*, which may be administered in doses of from \mathfrak{z} ij to \mathfrak{z} vj once a day. An equally good form of conium is Squibb's fluid extract. I usually prescribe this, and give it in doses of \mathfrak{m} xl or \mathfrak{z} j. Dr. John Harley, of London, has done much to give us a clear notion of the action of this remedy, and he has found it useful in chorea, epilepsy and other spasmodic diseases; he points out the necessity of obtaining the physiological effects of this and other drugs when we wish really to do good in affections of the nervous system. In epilepsy I have employed the fluid extract of conium in combination with bromide of potassium with good results.

Bromide of potassium also acts directly upon the spinal cord as a depressant. It lowers the activity of the motor tract (though in a lesser degree than conium) and diminishes reflex excitability. Its use is consequently indicated in all affections in which reflex action is abnormally great, and in many such we obtain immediate and permanent good results from its administration. In various forms of convulsions, the eclamptic attacks of children, of pregnant

and parturient women, bromide of potassium does good. Morbid excitement of the lumbar part of the spinal cord, as evidenced by nymphomania and satyriasis, is often relieved by this drug. Some forms of vomiting (in pregnancy, after inhalation of ether, etc.), spasmodic states of various sphincters are also to be cured by bromide of potassium. It is in the treatment of the great neurosis epilepsy that this medicine is most employed, and it is concerning its usefulness in this affection that great discussions have occurred. The use of bromide of potassium in epilepsy was begun by several physicians about the same time, but Drs. Brown-Séquard and Laycock were the first to call attention to it. The generally received opinion is that bromide of potassium is the medicine which possesses more power than any other over epilepsy; that in the majority of cases the frequency and severity of the seizures are very much diminished while the medicine is being taken (the symptoms soon reappearing if it be discontinued); and that a case here and there may be cured by its use. In hospitals with large numbers of epileptic patients, the effects of giving and withholding bromide of potassium are very strikingly in favour of the utility of the drug. For my part, I wholly accept this as a correct estimate.

There are a few general rules to be observed in the treatment of epilepsy by bromide of potassium. In the first place, enough bromide of potassium (and other bromides if you please) should be given to reduce the reflex function and keep it below the normal standard. A test of the sufficient action of the medicine lies in the reaction of the palate and fauces to irritation; a diminution or abolition of the well-known reflex movements of these parts indicating diminution of the reflex excitability. Another general rule is to give more of the medicine at night than in the daytime; a direction of great value, for which we are indebted to Dr. Brown-Séquard. We usually give three day-doses, and a dose in the evening twice or thrice the size of the day-dose. A third and most important rule is to administer the bromide of potassium in a perfectly continuous way for months and years. Dr. Brown-Séquard has known patients, who remained without seizures for two years while taking his prescription for mixed bromides, to have a return of convulsive seizures in a short time after ceasing the medication. I have seen similar though less striking results.

There are a few epileptics who cannot tolerate the bromides, who become easily 'bromised,' and whose attacks are made worse by these drugs. These paradoxical patients are very rare, I believe. While recognising the great value of Brown-Séquard's compound bromide solution (bromides of potassium and ammonium and iodide of potassium), I more commonly employ a simple solution of bromide of potassium, giving gr. v three times a day, and gr. xv or ʒj at bedtime, at first in adults. Children require relatively very large doses of the bromides; and contrary to what is sometimes taught, I see in anæmia no contra-indication to the use of the remedy, nor do I believe that any law can be laid down for the giving or not giving of it, from observations upon the retinal circulation. Such a view is based only upon belief in the more than doubtful physiological theory, that cerebral hyperæmia and anæmia are usually prime factors in the pathological state called epileptic.

(To be continued.)

ANATOMY AND PHYSIOLOGY.

HAKE ON THE USE OF ETHER AND CHLOROFORM IN PROFESSOR SCHIFF'S LABORATORY.—In the *Practitioner* for April, Dr. T. G. Hake gives the results he has witnessed in the physiological laboratory at Florence, of giving ether and chloroform to animals. Ether is usually preferred, because Professor Schiff finds that 'etherisation pushed to the very last stage of insensibility is never dangerous to life so long as one maintains the act of respiration, and even if one press the inhalation of ether yet further, so that the respiratory movements cease, or in other words, the appearance of death is complete, life is never menaced, if only, at the moment of the paralysis of the thoracic walls, inhalation be interrupted and a species of artificial respiration be immediately commenced by means of periodic compression of the thoracic parietes themselves.

'Chloroform has been preferred to ether because it acts more quickly, and its use is more agreeable to the patient. But chloroform has a paralysing action much greater than that of ether, and, in like manner, at least in man and mammalia, generally has a special influence on the nerves of the heart and vessels. If chloroform be pushed so as to produce a considerable weakening of the respiratory movements, the interruption of the inhalation may, in a majority of cases, lead to the re-establishment of respiration and afterwards of sensation; but sometimes, a short time after the commencement of inhalation, the force of the circulation is so enfeebled that it no longer renews fast enough the blood to the lungs.' . . . 'Death is sometimes sudden, but it may be preceded by signs of sinking of the pressure of blood in the vessels.' . . . 'If the action of chloroform be prolonged until respiration ceases, we are not even sure of being able to revive the individual after having re-established the respiratory movements, for these often again cease owing to the disturbance of the circulation, whilst the same movements, if restored after the inhalation of ether, become *always* more frequent in the individual when left to himself.'

He believes that 'the lethal effect of chloroform depends in part on individual predisposition, which the physician is unable to recognise'; that, whereas ether gives rise to paralysis of the respiration, vessels, heart, and motor nerves, in the order named, chloroform is irregular in its action, and sometimes produces paralysis of the vessels first, then of respiration, and finally of the heart. 'That the heart is the last of these three factors which dies,' he demonstrates thus. 'When by the action of chloroform the pressure in the vessels has gone down nearly to zero, and there is no visible pulsation, compression of the aorta between the crura of the diaphragm, or the mere compression of the abdomen, restores to the pulse its strength and frequency, and causes the pressure to rise to considerable height.' 'This fact proves that the heart, notwithstanding its apparent paralysis, is still able to maintain the almost normal pressure of the blood, and to contract with more strength than before, when the pressure is acting upon its walls, and opposing itself to their contraction.'

Professor Schiff's experiments on animals with ether, in more than three thousand cases have, with few exceptions, been without the occurrence of a death, but chloroform was fatal to a considerable number when he wished to push anæsthesia to its ultimate stage. 'He considers that chloroform

should be banished from practice as an anæsthetic agent, except in cases in which extraordinary resistance to the effect of ether shows itself, in which instances it might be allowed to mix a little chloroform with it, in order to produce the commencement of anæsthesia.' He has made some highly important observations upon the effect of the irritation of many sensitive nerves. 'The animal is etherised or chloroformed until respirations have ceased, artificial respiration is commenced, and when the animal begins to breathe automatically but weakly, there is a moment in which any strong mechanical irritation of the nerves above indicated produces a new and more persistent asphyxia; the diaphragm is relaxed, and it seldom happens that the animal is recalled to life.' This 'is now explained by Schiff's more recent experiments, in which mechanical irritation of a posterior spinal root—previously laid bare—produced paralysis of the circulation.' 'These experiments afford a warning of much importance to surgeons, not to continue an operation immediately on a patient's recovery from the excessive action of anæsthetics, but to wait until respiration has been energetically restored.' 'Professor Schiff killed some dogs in the first period of return from asphyxia produced by ether only, by raising with a tenaculum one or two posterior roots of the dorsal nerves; while in other dogs, prepared in the same way, in which the same operation preceded the division of these nerves in a somewhat more advanced period of the return of respiration, that function continued in its regular progress up to the time of consciousness being restored.'

[The reporter believes that the frequency of death from chloroform in Schiff's experiments on animals may be explained by his not having the means of limiting the proportion of chloroform in the air with sufficient accuracy. His own experience in giving it to the human subject has convinced him that it does not always prevent the shock of an operation (see his remarks in *Brit. Med. Journ.*, February 14, 1874, upon the causes which augment the effects of chloroform). Schiff's observations are specially valuable as showing the danger of continuing an operation if a patient is so intensely narcotised that the respiration is performed in a very defective manner. The reporter would be guided by the condition of the pulse in a doubtful case of the kind.—*Rep.*]

JOSEPH T. CLOVER.

PATHOLOGY.

MÉHU ON THE LIQUIDS EFFUSED INTO THE PLEURA.—A work on this subject recently published by Dr. Méhu (*Archives Générales de Médecine*) gives the *résumé* of a long series of experiments undertaken by the author, with the intention of throwing light on the differences between the physical and chemical qualities observed in the liquids of the thoracic cavity. From these experiments, M. Méhu has deduced the following conclusions. In pleuritic effusions the amount of mineral salts is nearly invariable, and always independent of the quantity of albuminous matters contained in them. This rule applies to all the serous liquids of the animal economy, as hydrocele, ascites, hydrarthrosis, hygroma, ovarian cysts, &c. Each kilogramme of liquid yields from 7·5 grammes to 9 grammes of

anhydrous mineral salts. Fibrine is more specially present in acute pleurisy in an average quantity of 0·4232 grammes; and it is also present in cases where the thoracic effusion is the result of some obstruction in the circulation of the blood in the heart or the great vessels; but it is then found only in small proportion, being on an average 0·149 grammes. Fibrine was not found in purulent liquids, nor in effusions brought on by the presence of heterologous products such as tubercle, cancer, etc. Whenever the weight of the dry residuum did not attain 50 grammes to the kilogramme of liquid (average 30·1 grammes), there was some impediment to the circulation of the blood in the heart or great vessels, and the effusion was owing to that obstacle (cardiac affections or cirrhosis). When the weight of the dry residuum left by the evaporation of 1 kilogramme of liquid exceeds 50 grammes (the average being 65 grammes, the lowest quantity obtained 58 grammes), and this liquid coagulates after operation into a mass of more or less consistence, it may be taken as certain that acute pleurisy is present. According as the amount of fibrine is large, the patient rapidly recovers; a single puncture generally effecting a cure. If in some cases two punctures have been made, it is not always because the liquid has reproduced itself, but because the operator, fearing some annoyance to the patient, has chosen to extract only a portion of the liquid in the first instance. When the condition of the patient calls for several successive punctures, the proportion of fibrine increases in proportion as the disease is near cure. On the contrary, the fibrine remains in very small quantity, or is not present at all, if the disease show a tendency to grow worse. Practically, at the bed-side, every pleural liquid for which the gravimeter indicates a density above 1·018 at a temperature of 59° Fahr., coagulates and which sets by degrees into a more or less consistent mass, betokens a clearly defined acute pleurisy, which will be cured the more rapidly as the coagulum becomes more firm. Every pleural liquid of which the gravimeter indicates a density below 1·015 at the temperature of 59° Fahr., indicates that the effusion depends on the presence of some impediment to the circulation of the blood in the heart or great vessels. Hydrothorax is present. Here the prognosis depends on the primitive lesion, generally more serious than the effusion itself. Every pleural liquid of which the gravimeter indicates a density above 1·018 at a temperature of 59° Fahr., and which does not yield any fibrine, indicates a lesion of the pleura, due to the presence of heterologous product, such as tubercle or cancer, generally a very serious lesion, so that these liquids are generally an unpleasant prognosis.

In all cases M. Méhu recommends that a temperature of fifteen degrees (59° Fahr.) should be taken as a term of comparison, without having recourse to calculations to correct it.

ON ANEURISMS DEVELOPED UPON BRANCHES OF THE PULMONARY ARTERY, BORDERING UPON CAVERNS.—In the *Progrès Médical*, there is an interesting paper on this subject. The branches of the pulmonary artery, which ramify in the walls of caverns in phthisical subjects are most frequently obliterated. This is a point upon which all authors since the time of Laennec insist, and upon which the researches of Nat. Guillot have more particularly thrown light. In some cases, however, these vessels remain permeable, but undergo in a localised point a histological modification, as a consequence of which

they become dilated, and there can then be found a small aneurism projecting into the cavern.

These cases are relatively rare, but many facts recently presented to the Anatomical Society lead us to think that by more rigorous research they would more frequently be discovered. In all the cases where it has been studied, the process appears to have been the same; it can be summed up thus: denudation of the vessel over a limited point, endarteritis in the embryonic transformation of the wall at this level; then simple dilatation or aneurism; lastly, most frequently rupture of this aneurism. The vessels injured by this alteration are not the capillaries; their calibre has varied from a half to three millimètres. They were generally parallel to the cavern; in M. Lepine's case the artery was perpendicular. The hæmoptysis following the rupture has generally been very abundant, and has almost always been followed by rapid death; in some cases, however, the hæmorrhage has ceased and the patients have not immediately succumbed, and it has been possible to find at a later period the orifice obliterated by clots of blood of different ages. Occasionally there appears to have been at several times successive ruptures and obliterations. According to Powell these aneurisms are developed especially in cases of torpid (quiescent) phthisis, where they exist on one side only of old caverns; and, on the contrary, the hæmorrhage from simple erosion of the vessel will be rather the result of the active process of rapid phthisis.

Again, in the two cases, this change in the vessel would not be in any wise possible unless it were by one single point in its surface adherent to the diseased pulmonary tissue, the chances of obliteration being, on the contrary, much greater if the entire vessel dip into the morbid product.

An examination of the observations shows indeed, that in the majority of cases the pulmonary tissue over the wall of the vessel opposite the aneurism is almost healthy; but as to the first point, if there are many facts in favour of the phthisis being evidently chronic, there are others absolutely contradictory.

The rupture of these aneurisms is not forced, and although they have seldom been detected except after profuse hæmoptysis, it has been possible to discover those which had not burst. But if we expect that in the cases of extensive pulmonary alterations, the field of distribution of the pulmonary artery is more or less contracted, and that, as a consequence, the vascular tension ought to be there increased, if we add to that the feebleness of the wall of the vessels, we cannot be surprised that this rupture should be the most ordinary result. According to Jaccoud, it will also be more frequent or more early, if there does not generally exist in these cases a dilatation of the right auriculo-ventricular orifice, the result of which ought to be to diminish the volume of the sanguineous shower.

As for the occasional causes of the rupture they are unknown; however, it has appeared in some cases that the hæmoptysis has been preceded by a violent fit of coughing, but we ought always to ask ourselves if the fit of coughing was not itself the first symptom of the hæmorrhage.

It is very evident, again, that these cases cannot be foreseen, and up to this time they have never been diagnosed before the rupture; but if we observe at an advanced period of phthisis a profuse hæmoptysis to come on suddenly, we should consider it

due to the rupture of an aneurism, and we ought not on that account to neglect to treat the patient; it will, quite on the contrary, be more formally indicated, to seek to arrest at once the hæmorrhage, since we know that in certain cases the aneurism has been able to be obliterated by a clot of blood.

J. B. BRADBURY, M.D. (Cambridge).

SURGERY.

HORAK ON A CASE OF PROLAPSE OF THE OMENTUM THROUGH A PUNCTURED WOUND OF THE ABDOMEN.—Dr. Anton Horak of Brunn reports (*Medicinisch-Chirurgisches Centralblatt*, no. 15, 1874) a case of a man aged forty who, during an attack of delirium tremens, had stabbed himself in the epigastric region with a large carving-knife. Through this wound, which was three centimètres in length, and extended transversely from the linea alba to the left hypochondrium, there protruded a red and sanguineous tumour resembling a gland, the base of which was compressed by the cut edges of the abdominal wall. Manipulation of this protrusion caused much pain and hæmorrhage. The parts around the wound were hard and swollen, and gave a dull sound on percussion. The gastric region was much distended, and pressure here caused nausea. Dr. Horak at first thought that the tumour consisted of a portion of pancreas, because it very much resembled externally the acinous structure of this gland; on further consideration, however, and after bearing in mind the deep situation of the pancreas and its relation to the stomach, he came to the conclusion that the protruded mass was composed of degenerated omentum. A ligature was placed round the base of the mass, just above the seat of constriction, at the wound in the abdominal wall. In order to guard against hæmorrhage, very strict local and general antiphlogistic treatment was carried out. The patient was carefully watched, and his mental disturbance treated by large doses of opium. The ligature was tightened on the following day, and on the third day the portion of tumour external to the ligature was removed. A raw surface was left, which granulated and speedily closed by cicatrization, the remaining cord-like base of the protrusion becoming more and more retracted into the abdominal cavity. On the seventeenth day Dr. Horak discontinued his professional visits, and the patient ultimately made a complete recovery. The portion of the fleshy mass which had been removed after the application of the ligature was examined microscopically, and found to be a piece of compressed omentum.

MEYER ON ARTICULAR NEUROSIS.—Dr. Moritz Meyer, in a paper read before the Medical Society of Berlin, and published in the *Berliner Klinische Wochenschrift* (no. 16, 1874) attributes to Stromeyer and Esmarch the merit of having of late directed particular attention to the obscure and pseudo-inflammatory affections of joints, which were first described nearly half-a-century ago by Brodie as hysterical articular lesions. These affections, Dr. Meyer states, have their seats in the nerve-trunks which provide the articular capsule and the soft coverings of joints with sensory twigs, and are revealed by pains felt during movements of the affected joints, and are not unfrequently the sole cause of articular immobility lasting for years, and in some

subjects to the end of life. This form of neuralgia, for as such the affection may be rightly regarded, sometimes occurs without any appreciable cause; at other times it is undoubtedly a result of some psychical affection or intense emotion. It often follows some mechanical lesion, as contusion or distortion of a joint, and is occasionally dependent on reflex action in cases of gastric disturbance and irritation of the urinary and generative organs. The diagnosis of articular neurosis, and particularly its distinction from inflammatory affections of joints, is often very difficult; but this is an important matter, since rest and antiphlogistic treatment, which are so serviceable in the treatment of the latter affections, are contra-indicated in cases of articular neurosis, which require movement of the affected joint, good diet, and tonics. The guiding-points in the diagnosis of the neurotic affection are the following. Nocturnal pains are almost invariably absent in this affection; slight digital contact with the affected joint is generally very painful, whilst firm pressure and concussion of the cellular extremities of the bones do not cause much distress; temporary œdema and puffiness of the integuments are frequently to be met with; the temperature of the affected joint sometimes undergoes periodical variations; notwithstanding absolute rest of the joint, and corresponding limb, the muscles undergo very little wasting; the very slight objective phenomena bear but little relation to the severe pain complained of by the patient; if the attention of the patient be diverted for a time from the affected part, the surgeon may often move the parts about the joints, and the limb, without causing pain. Articular neurosis often ceases suddenly on the appearance of other hysterical affections, through violent mental impressions, after sudden and violent movements caused through accident, and, in cases of the reflex variety, after cure of the distant and primary affection. The best treatment, according to Stromeyer, consists in the administration of tonics, cold and sea-water bathing, shampooing, and profuse movement of the affected joint. Hypodermic injections of morphia, and the administration of chloroform are recommended by Esmarch as excellent means of causing relaxation of stiff joints. Dr. Meyer recommends in addition to these plans of treatment a powerful induction-current, applied directly to the painful joint. This, he states, acts readily as an anæsthetic and curative agent. Four cases are reported, in which severe articular neurosis was thus successfully treated. W. JOHNSON SMITH.

CARPENTER ON MALIGNANT PUSTULE.—Dr. Alfred Carpenter has printed (with additions) a paper read by him before the Medical Society of London in November last. He has met with five cases of charbon, and says that Dr. Farr informs him that, although reckoned rare in England, twenty-one deaths from it were registered during the five years ending December, 1871—viz., in 1867, six; in 1868, three; in 1869, four; in 1870, three; in 1871, five. In all Dr. Carpenter's cases the pustule was on one or other lip.

The first case, in a male inmate of St. Thomas's Hospital, aged thirty-six, was fatal in six days. The second patient, a grocer, aged forty-four, died about the eleventh day. A girl, aged twenty-two, died on the eighth day. The fourth patient, a young lady from the West Indies, died on the sixth day; but the fifth case, a lady, aged thirty-six, born in India, recovered, after nearly seven

months' illness, attended with pyæmic symptoms, jaundice, and phlebitis of the abdominal veins, with articular pains and nodes on the tibiae. Dr. Carpenter attributes her recovery to the free use of liquor ammoniæ—five minims of the strong solution being given in water every hour at first, and continued afterwards. Dilute nitric acid aggravated her symptoms. In the discharges Dr. Carpenter found 'a few minute rod-like bodies, which rapidly developed into a fungus growth,' which he did not find figured in any work on microscopic fungi to which he had access. 'It appeared to be one of the hyphomycetous fungi, allied to botrytis and penicillium, though it may possibly belong to ascomycetes, the terminal fructification in some cases appearing in asci.' No communication with diseased animals was traced in either of the cases.

The same pamphlet contains an account of a case of recovery from glanders, or acute farcy, in a grazier. This favourable termination is attributed to the use of ammonia, although mercury was also exhibited.

W. BATHURST WOODMAN, M.D.

LE FORT AND OTHERS ON THE PRODUCTION OF ANÆSTHESIA BY COMPRESSION.—At a sitting of the *Société de Chirurgie de Paris*, held June 21, M. Le Fort read a communication on some cases in which he had obtained surgical anæsthesia by the sole employment of compression by the method of Esmarch; he attributed this effect to the energetic compression of the sensory nerves by the constricting band placed round the root of the limb. He considered that there was here a most valuable agent in producing anæsthesia, should the feeble condition of the patient not permit the use of chloroform, or demand the least possible loss of blood. In the discussion, M. Demarquay said that he had already attempted to induce anæsthesia by ischæmia, by applying Esmarch's apparatus in patients afflicted with varices of the lower limbs, but that he had found on removing the bandage that the sensibility continued, though considerably duller. M. Demarquay had in his cases suppressed the constrictor band placed on the root of the limb, and it was to this that M. Le Fort attributed the complete results he obtained; in a word, M. Demarquay kept within the bounds of producing anæmia of the limb, whilst M. Le Fort directly suspended the nervous action by the energetic constriction to which he submitted the nerves, by concentrating this constriction upon a limited portion of their extent. M. Verneuil, from the experiences he had had of Esmarch's method, had determined, 1st, that complete ischæmia, produced by pressure for fifteen minutes, admits the persistence of sensibility; 2nd, that after removing the apparatus it manifests itself some time after the operation, a consequence no doubt of the paralysis of the capillaries produced by the pressure, the free loss of blood necessitating the ligature of a lesser or larger number of arteries; there is therefore an exaggeration in saying that, owing to Esmarch's apparatus, operations can be performed without the loss of a single drop of blood. If the wadding dressing be applied after similar operations, the oozing of blood which occurs soaks it and renders it defective, so that the intention of the method of dressing by occlusion would be, according to M. Verneuil, analogous to that of Esmarch.

EDWARD BELLAMY.

MATERIA MEDICA AND THERAPEUTICS.

PAUL AND OTHERS ON THE TREATMENT OF TÆNIA.—The *Bulletin Général de Thérapeutique* of June 30 contains the following report of an interesting discussion which took place at a meeting of the Société de Thérapeutique on the 10th of the same month. 'M. Constantin Paul referred the society to an observation published in the *Revue Médicale de l'Est* (for June 1, 1874, p. 415), by M. Spire, of Blamont. It had reference to an infant of thirteen months having a tænia, which was expelled after the administration of one gramme of the ethereal extract of male fern and three grammes of the fern powder, to be taken in six doses, at intervals of ten minutes; 10 grammes of the pomegranate root bark having been previously administered without result. M. Paul called attention to the two following points; the very considerable dose of the ethereal extract employed in this case, and the frequency of tænia amongst infants to whom raw meat is given. In the instance mentioned, the infant had partaken of cooked pork ever since it was five weeks old. M. Limousin did not consider the dose of 1 gramme of the ethereal extract to be unduly large; he had successfully administered to an infant four years old 4 grammes of that extract, which, in his opinion, is not toxic. M. Martineau, however, had seen rather serious accidents produced in a young man, twenty-one years of age, to whom he had administered 4 grammes of the extract. M. Créquy had for some time recommended the employment of capsules, each containing 50 centigrammes of the ethereal extract, and had never observed any ill effects; this treatment, applied by him a dozen times, had only once been unsuccessful. The capsules should be thin, otherwise they can only be dissolved at one point more or less removed from the intestine, and thus can have no action on the tænia. M. Delieux de Savignac thought that we must, before having recourse to the ethereal extract, employ the seeds of the pumpkin, which have always yielded him excellent results. He proceeds thus: he makes an emulsion with 60 to 80 grammes of decorticated pumpkin seeds, to which he adds 30 to 40 grammes of castor-oil; then, two hours afterwards, he administers 60 grammes of castor-oil. M. Trasbot remarked that amongst animals, and particularly in dogs, tapeworms were very frequent, and that all the measures employed, pomegranate root, male fern extract, kouso, were alike efficacious; in particular, he spoke of a mixture of sulphuric ether and aloes, which afforded excellent results. In reference to food as causing tænia, we must distinguish the flesh of the ox from that of the pig and the sheep. As the first does not contain cysticerci, it appears to him difficult that it should give rise to the presence of tænia. M. Dally thought that we should not exclude the flesh of the ox as a source of tapeworm; for, in the study that he had made of the Abyssinians, he had shown that the frequency of tænia was due to the consumption of the raw flesh of the ox. M. Dujardin-Beaumetz was of opinion that in the treatment of tapeworm, we must, as remarked by M. Laboulbène, attach great importance to the moment when the purgative is administered. The anthelmintics do not kill the tænia; they stupefy it; and we must seize upon

the moment when the tænia is no longer fixed to the intestinal walls in order to expel it by a purgative. He, however, admitted that it was very difficult to fix the time correctly. M. Féréol said that there were cases in which the tænia resisted, whatever be the method employed; he had at that time a case under his eyes where he had nine times made attempts that had all been frustrated; the tænia had always reproduced itself. He had employed all the anthelmintics in vogue, and had been obliged to follow the indications laid down by M. Laboulbène for the administration of the purgative. All had failed. M. Constantin Paul believed that in many cases it was very difficult to obtain the complete extraction of the tænia. He nevertheless mentioned a remedy given at Geneva (where the bothriocephalus is frequent) with excellent results. It consists of Peschier's pills, made with the ethereal extract obtained with the fresh buds of the male fern. The pills are thus given: the evening previously the patient is put on a milk diet, and afterwards twenty pills are given in two doses. This remedy produces very sharp colic. M. Blondeau called to mind that in the *Traité de Thérapeutique* of Trousseau and Pidoux one all along finds the treatment advocated (*préconisé*) by M. Laboulbène. In connection with the bothriocephalus he related the following fact, which had been communicated to him by M. Potain. It referred to a family where the presence of this worm had been observed. This family had never travelled, and, above all, had never been in Switzerland. In seeking for an explanation of the cause of this fact, it was learnt that the servant had been Swiss, and had for a long time a bothriocephalus. M. Legroux had seen an analogous case. It referred to a lady who had contracted a bothriocephalus in Switzerland. Returning to Paris, she underlet a portion of her house to a gentleman, who, never having travelled, became at length also infested by the same cestode. [The reporter is desirous of expressing his surprise that M. Trasbot should be ignorant of the existence of cysticerci in beef, after the experimental proofs adduced first by Leuckart, in Germany; secondly, by the reporter, with Professor Simonds, in England; and thirdly, by St. Cyr, in France. The distinguished Parisian helminthologist, M. Davaine, has given an excellent summary of these experiences in the exhaustive article *Les Cestoides*, in the newly issued edition of the *Dictionnaire Encyclopédique des Sciences Médicales*.—*Rep.*]

T. S. COBBOLD, M.D.

LIEBIG ON THE OPERATION OF COMPRESSED AIR.—Dr. von Liebig, of Reichenholt, has in a recent number of the *Aerztliches Intelligenz-Blatt* of Munich, given an account of the further results of his experiments on the effects of compressed air, of which the following is an abstract, at least of its more purely therapeutic portion.

Dr. Liebig had on a former occasion determined the mechanical effects of compressed air on the system, and also made some experiments on the amount of carbonic acid given off under it; his further researches have shown, that any increase of expired carbonic acid coincides with a greater inspiration of atmospheric air, and that the quickness of respiration has a much greater effect in producing carbonic acid, than its depth. On the whole, compressed air has not in itself any very natural effect on the production of carbonic acid. As it has been found that the number of inspirations is reduced

under increased pressure, so it is found to be greater under diminished pressure, and it seems probable that under the latter circumstances the quantity of carbonic acid expired may be greater.

From his experiments on oxygen Dr. Liebig deduces the inference, that there is undoubtedly increased absorption of oxygen under high pressure—relatively amounting to 18, and absolutely to 22 per cent.

The increased absorption of oxygen under heightened absorptive pressure, helps materially to explain the good effects of the pneumatic apparatus on patients. These effects are most strongly manifested in diseases which are attended with a deficient supply of oxygen, and we understand now how so much relief is afforded by increased pressure to old chronic bronchial catarrhs and emphysemas—why the livid skin resumes its natural tint, and appetite and strength return. These patients have to breathe as hard as they can to get a supply of oxygen, and increased pressure makes their respiration easier and facilitates the absorption of oxygen, which is equivalent to an absolute increase of the amount of oxygen in the blood. The improvement of many anæmic cases is also rendered intelligible. The mechanical effect of compressed air in chest-affections further gives the power of taking deeper inspirations, a power which lasts after the treatment is over—and therefore greatly increases its value.

We now see that the operation of compressed air is partly mechanical, partly chemical. The first facilitates the return of the blood to the heart, while it makes pressure on the capillary vessels. We have to thank it for the favourable effects in neuralgias, especially of the head, in headaches and toothache, and in the stopping of bleeding from the nose or lungs. It also, if seasonably applied, quickly checks acute catarrhs of the larynx, the bronchi, and the nose and ears; and no treatment gives such relief in whooping-cough.

Its chemical operation gives an additional supply of oxygen to the blood, and relieves chronic catarrhs, emphysemous asthmas, anæmia from loss of blood, or after illness, and finally amenorrhœa.

In cases of recurrent bronchial catarrh, with asthma, it is frequently possible to ward off an attack.

In children especially, who suffer from an early age from bronchitis and asthma, Dr. Liebig has often observed that southern health-resorts or bath-treatment only gives temporary relief, while by compressed air the tendency to relapse is greatly diminished. He also finds the use of the pneumatic chamber of much use in children with imperfectly developed chests.

In an anæmic patient with excessive nervous sensibility, when all other treatment at Reichshall had failed, the pneumatic chamber had the most wonderfully soothing and strengthening effect.

In cases of recent pleuritic affections Dr. Liebig has not used compressed air, because baths, fresh air, and whey, were sufficient for the cures. But in cases of old pleuritic exudations, in which the walls of the chest were partially sunk, great advantage has been derived from the pneumatic chamber, which, however, is only to be used in the absence of a febrile condition.

In slight affections of the heart, depending on defects of the right side, slight degrees of pressure have given favourable results, and improved the general health. In more serious affections of the heart and of its left side, compressed air is no longer

used, partly on theoretical grounds, and partly on account of its having aggravated the sufferings in one case.

Although increased pressure is often useful in anæmia, a certain number of such cases are undoubtedly benefited by the diminished pressure of moderate heights, but which set of cases are suited for the one or the other mode of treatment is as yet imperfectly determined.

The use of pneumatic chambers is extending fast to many watering-places, and the chambers of Reichenholt have been extended, so that fifteen persons can sit in them at once. J. MACPHERSON, M.D.

ELECTRO-THERAPEUTICS.

NEWMAN ON ELECTROLYSIS IN THE TREATMENT OF STRICTURES OF THE URETHRA.—Dr. Newman, of New York (*Archives of Electrology and Neurology*, no. 1, New York: 1874.), has treated a number of cases of simple and complicated strictures of the urethra by the electrolytic method, which was, without exception, successful. Although he has no failures to record, he does not wish to condemn every other treatment, or to say that all strictures can be cured by electrolysis; yet he is so well satisfied with the results of the method that he will not use any other mode of cure.

He follows the method recommended by Mallez and Tripiér, viz., to use the negative pole exclusively for the 'absorption' of the stricture, while the positive is applied outside. A moderate current should be used, for, by employing a superabundance of electricity, too much inflammation is induced, destruction of the surrounding healthy tissue takes place, suppuration intervenes, and thus aggravates the disease. The current should therefore never be strong enough to lead to destruction of tissue, but simply restore the affected parts to their normal condition. He uses Drescher's battery, in which the current can be regulated cell by cell, without interruption, and the quantity of electricity in all the cells can be increased or diminished at will by the screw-lifting arrangement, by which the elements can be immersed into the battery-fluid to any desired depth. The catheter used for the negative pole consists of a metal bulb, to which a rod of wire is attached, and over which a flexible catheter is fixed, cut off at its extremity, and connected with the metal bulb, thus obtaining a smooth and continuous surface. The bulb is egg-shaped, about half an inch long, its length proportioned to its diameter. The elastic catheter acts as an insulator, and at the free end the rod is connected with the conducting-wire of the negative pole of the battery. The catheters are made in sets of different sizes.

The author then proceeds to give a somewhat fanciful description of the effects of the negative pole upon the mucous membrane, amongst which he mentions 'agitation' and 'coagulation (!) of alkalies.' Some experiments on the urethræ of dogs are given, but they fail to elucidate the author's meaning, except in so far as the prejudicial effect of too strong currents is concerned.

Dr. Newman says that there are three principal methods of using electricity for the cure of stricture; viz., electrolysis with a mild current, the galvanic cautery, and powerful electrolysis. We have, however, up to the present time, never heard that anyone

selected the last two proceedings, which must in the nature of things be thoroughly objectionable. Dr. Newman says that 'the galvanic cautery violently forces a passage, burns its way through the impediment, the result being a firm and hard scab on the walls of the urethra. After the operation, the patient must be left alone until the scab has come off, and many weeks must elapse before a normal mucous lining is formed, even on a healthy urethral wall. A scab thus produced firmly adheres to the walls of the urethra, and cannot without danger be removed by the operator; interference would be highly reprehensible. If an attempt be made to accelerate the separation by instrumental manipulation, serious consequences are sure to follow. The boundary between the scab and the adjacent healthy mucous lining is always a weak spot, and any exploring instrument used in contact with or beneath the scab, might cause rupture of the urethra.' We trust that in framing these remarks the author may have drawn entirely upon his imagination, for nothing could be more unjustifiable than the use of the galvanic cautery for stricture of the urethra.

The time used for the electrolytic operation is from three to four minutes; the current should at first be very gentle, and gradually increased until the patient feels a slight pricking and burning; when the operation is over, the instrument should only be disconnected after the current has been gradually reduced to zero. On withdrawing the bougie electrode, its metal bulb is seen surrounded by a frothy yellowish mass, looking like coagulated albumen. This product is part of the stricture which has been decomposed. The operation should be repeated fortnightly or monthly, until the urethra has entirely recovered.

Most of the cases recorded by the author seem to have been cured by two or three operations. The descriptions of some of the cases are not sufficiently detailed, and it is not always easy to see whether dilatation has not had something to do with the successful result.

BEARD ON A NEW METHOD OF TREATING MALIGNANT TUMOURS BY ELECTROLYSING THE BASE. Dr. Beard, of New York (*Archives of Electrology and Neurology*, no. 1, New York, 1874), adopts the theory that there is a constitutional cancerous diathesis, which, like the tubercular or gouty diathesis, is subject to the laws of hereditary descent; but that, for this diathesis to develop into positive local disease, it is necessary that there should be an exciting cause. The chief exciting causes of malignant tumours are, according to him, injuries, and damp and cold. The latter influence he derives from the statistics of Professor Andrews, of Chicago, who has shown that in the States cancer diminishes as we proceed to the west or south—away from the sea-coast and towards warm latitudes. The cancerous tumour therefore he considers a local disease, which, whatever constitutional treatment we may adopt, should be treated locally, and by some method of local treatment that acts not only on the body of the tumour, but also on the surrounding tissue; and the earlier such treatment is used, the better the prognosis. He says that cancer spreads like a fire on a prairie, and we must fight it as we fight a great fire, not by useless efforts to save the parts already destroyed, but by drawing a cordon round it, between it and the healthy tissue.

Taking this view, he looks upon the ordinary method of removing the tumour by excision, and

then closing the wound so that it may heal by first intention, as one that is sure to cause a relapse; inasmuch as an areola of morbid or semi-morbid tissue is left mingled with healthy tissue, and the cancer-cells are thus shut up in a soil best of all adapted to nourish them.

The ordinary method of electrolysis, where needles are inserted into the body of the tumour, has the advantage of relieving pain, and causes a diminution, and in exceptional instances, total destruction of the growths; but is in most cases ineffectual to retard the progress of the disease. He has therefore, for some time past, used what he calls electrolysis of the base, which is performed in the following manner. The patient is fully etherised. If the tumour be small, the positive needle is inserted underneath the tumour and near the border; the negative needle is then inserted also underneath the tumour, at some distance below the base of the growth, so that the point emerges on the opposite side. Active electrolysis is now commenced, and must be evidenced by yellowish foam appearing at the cathode, which gradually becomes loosened. As the action increases the cathode may be slowly worked from side to side, with a slight cutting motion, so as to undermine the tumour. The positive needle meanwhile remains inside; it becomes firmly adherent through oxidation, and is not removed until the end of the operation.

After the tumour falls off, through the thorough undermining of the base, the latter may be worked up in all directions with the needles, or with a harrow electrode, which Dr. Beard has devised for this purpose. After the removal of the growth the position of the poles is changed, so that all parts of the surface may receive the benefit of the action peculiar to both poles. If the tumour be a large one, it is better to have it first removed by the knife, and the base can then be worked up in the manner just described. The cavity after the operation has a charred appearance. The time required for the operation varies from ten to forty-five minutes. Little or no pain follows. The needles used are long, spear-shaped, double-edged, and tolerably short, so that a slight cutting action may be combined with the purely electrolytic action. They are not insulated, excepting that portion which is grasped by the hands in operating. From sixteen to thirty-two cells of Stohrer's battery are requisite.

The advantages of electrolysis of the base of the tumour are:

1. *Less liability to recurrence.*—When both poles of the battery are inserted into the tumour in the way described, the vibrations of the electric force not only pass between the electrodes, but extend to a considerable distance in all directions, whereby the nutrition of the surrounding tissues is modified. In this way it is possible that the degeneration of healthy into morbid tissue, may be prevented at a distance from the needles. Of course, it is necessary that the operation should be thoroughly performed. If the base be but half electrolysed, if patches of morbid tissue be allowed to remain, then there will most likely be a relapse. It is better not to use the method at all than to use it timidly or imperfectly.

2. *Less hæmorrhage than in other modes of operating,* owing to electrolysis coagulating the blood, constricting the tissues, and slightly cauterising them. Of course, when a considerable artery has been ruptured, it should be tied, but ordinary parenchymatous hæmorrhage is quite controlled.

3. *Less liability to shock*, even in very old and feeble persons, and after long applications of strong currents. Dr. Beard looks upon the electric current as one of the best antidotes of shock, seeing that it is useful as a means of resuscitation.

4. It is followed by a *more satisfactory healing* than other operative procedures.

5. *Pyæmia* and *septicæmia* are less likely to follow electrolysis than other surgical operations.

6. Many patients *dread the knife*, without reason or common-sense; but patients are not expected to exercise reason or common-sense; and such persons are willing to submit to electricity, however employed.

The disadvantages of the method are, that more or less bulky apparatus is required, that more time is necessary than for excision, that irritative fever follows a powerful and prolonged application, more especially on the second and third day, and when great sloughing ensues, in very vascular growths, there may be secondary hæmorrhage from blood-vessels that become involved.

Dr. Beard has not appended any cases to his paper, and we trust he may soon give us a full description of all malignant tumours treated by him in this manner.

DERMATOLOGY.

COLOMIATTI ON THE STATE OF THE MALPIGHIAN LAYER IN PSORIASIS.—Dr. Colomiatti, in a paper read before the Royal Academy of Medicine in Turin, and published in the *Giornale* of that society for June 10, describes the results of the examination of the skin of a man aged thirty, who had died in hospital while suffering from psoriasis. The disease first appeared as psoriasis guttata, and subsequently assumed the nummular, figurate, and diffuse forms. At one time it was accompanied with scaly eczema. At the time of death, nearly the whole body was affected.

Twenty-four hours after death, pieces of skin were taken from various parts, some being derived from parts where cadaveric maculæ were present. The pieces were left in Müller's fluid for four or five days, and were then placed in ordinary alcohol. Fine sections were made, and examined under the microscope, some in glycerine, some in damar; in all, it was found that one of the principal lesions consisted in hypertrophy of the papillæ, with dilatation of the capillaries and much sanguineous injection. The horny layer of the epidermis was wanting, and the more superficial layers were detached from the Malpighian; these elements, together with those of the horny layer itself, formed scales, which became detached during the process of preparation. All this could be seen with a low magnifying power, corresponding to Hartnack's no. 3, with no. 4 objective. It was seen that the interpapillary prolongations

of the epidermis were much more developed than in the normal state, and that, on raising them from the hypertrophied papillæ, there existed between one papilla and another a more or less deep depression, from the bottom and sides of which epidermic cells were detached; that the epidermic covering in the apex of the papillæ was very scanty; that there was not only much capillary injection in the papillæ, but also some extravasation; and that, where there was no extravasation, the capillaries were contorted like varicose vessels, and formed balls at the apex of the papillæ, with some very scanty connective tissue at the free margin.

On using a no. 8 objective, Dr. Colomiatti found that the hypertrophy of the papillæ did not depend merely on dilatation of the capillaries, but that there was also an increase of the connective tissue, consisting of a numerical increase of the cells, but especially of the hyaline substance. Some of the cells were round, small, like wandering cells; some were spindle-shaped; and several were furnished with numerous prolongations, some of which were branched, slender, and long, and were directed towards the circumference of the papillæ.

In the Malpighian layer, with Harnack's no. 8, Dr. Colomiatti saw the hair-like processes of the cells, and the spaces between them better than in any other parts. With an immersion-objective no. 9, and an ocular no. 4, he found that, while in some parts the greater part of the cells also retained almost their normal size, in many there was a defect of protoplasm; and these presented the longest processes. The protoplasm in all the cells had an appearance which might be called homogeneous; it was well circumscribed at the periphery, from which the hair-like processes were seen to arise. These, being derived from the protoplasm itself, were nearly hyaline. The number of processes from each cell was in some places increased, in others less than normal; so that the spaces were in the first case numerous and narrow, and in the second fewer and larger. No enlargement was observed at the free end of the processes; on the contrary, they were almost conical, their base being continuous with the cellular protoplasm. The scarcity and homogeneity of the protoplasm were most marked in the cells immediately covering the hyaline layer of the papillæ. The papillæ themselves were relatively much elongated and narrow, and their greatest diameter was perpendicular to their point of implantation. Some of the hair-like processes were evidently implanted in the hyaline layer of the papillæ, and, meeting the prolongations of the connective-tissue cells, joined them at their apices, or if they did not so, were so closely connected with them that no point of separation could be discerned.

In many of the epidermic cells there was a slight serous infiltration, like that which occurs in the early stage of the pustules of small-pox.

Dr. Colomiatti believes that in addition to the signs described by other writers, psoriasis is characterised by scantiness and homogeneity of the protoplasm of the cells of the Malpighian layer, with slight serous infiltration of the cells; by their elongation, and by excessive development of the hair-like process, with exaggeration of the intervening spaces.

Dr. Colomiatti has also examined portions of skin removed from a patient under the care of Dr. Gibells, and has found similar appearances to those above described.

A. HENRY, M.D.

MISCELLANY.

It is proposed to open in Berlin, on October 15, an institution for the instruction of ladies in medicine and pharmacy.

ASSOCIATION OF HUNGARIAN NATURALISTS AND PHYSICIANS.—The meeting of this Association will be held in Raab, commencing on August 15, and ending on the 23rd.

SMALL-POX AND TYPHUS IN STOCKHOLM.—Small-pox and typhus fever, which have been prevailing extensively in Stockholm, showed a decrease in the week from July 4 to 10. There were 54 new cases of small-pox, and 10 deaths, against 76 cases and 18 deaths in the previous week. There were remaining under treatment 177 cases of small-pox, and 43 of typhus.

CHOLERA IN HUNGARY.—The official report of the late outbreak of cholera in Hungary shows that from September 1872, till the end of 1873, 190,000 fell victims to this dreadful scourge. The official weekly health returns of some of the Hungarian towns are strikingly large; in Pesth, for instance, from June 21 to June 27 of this year, 239 births were registered, and 262 deaths. The weather in that week was moderately cool, therefore in no way unfavourable, and yet the excess of deaths over births among the 260,000 of the capital amounted to twenty-three.

ASSOCIATION OF GERMAN NATURALISTS AND PHYSICIANS.—The Forty-seventh Annual Meeting will be held in Breslau during the week from September 17 to 24. The following is the programme of the daily proceedings: Thursday, September 17, evening receptions in the Liebig's rooms (Gartenstrasse); Friday, 18th, 9 to 12.30, First General Meeting; 1 P.M., Opening of Sections; 3 P.M., Festival in Springer's Rooms; evening, Conversazione in the Zoological Gardens. Saturday, 19th, 8 to 1, Meetings of Sections; dinner in the various hotels and restaurants; 7 P.M., Concert. Sunday, 20th, Excursions to Fürstenstein; to Landeck, by invitation of the town to the medical sections; and to Sibyllenort. Monday, 21st, 10 to 12.30, Second General Meeting; 3 P.M., Festival in Springer's Rooms; 7 P.M., Performance in the Town Theatre. Tuesday, 22nd, 8 to 1, Meetings of Sections; dinner in hotels and restaurants; evening, Ball given by the merchants. Wednesday, 23rd, 8 to 1, Meetings of Sections; dinner in hotels and restaurants; evening, Festival given by the town of Breslau. Thursday, 24th, 10 to 12.30, Third General Meeting; 3 P.M., Festival Dinner at Springer's Rooms.

PRINCE LEOPOLD.—A good deal of prominence has been given during the last few days, and on former occasions, to telegrams condoning the serious illnesses of Prince Leopold. It may be well, therefore, to explain that the illnesses to which reference is thus made are nothing more than the accidents which from time to time rarely fail to embarrass a young man who suffers from the particular form of constitutional delicacy to which the young prince is liable. It has been already made known that Prince Leopold is one of those persons who have an inherent thickness of blood, which makes every slight scratch give rise to a more or less serious hæmorrhage, and makes the little accidents and bruises which are incidental to active life, matters of more or less serious subsequent inconvenience. It is rather a hard fate, however, that every one of these should be chronicled, and that every time the prince cuts his finger, or that his foot slips, and he gets a little strain or a bruise, competing telegraphists should fill the newspapers and posters with paragraphs concerning his serious illnesses. We have all a natural and loyal interest in the health and welfare of the Queen and her family; but we are inclined to think that in the case of Prince Leopold such interest would be best shown by letting him alone a little.

PROFESSOR LEBERT of Breslau has resigned his chair, and has gone to practise as a bath-doctor at Bexh, canton Vaud, in Switzerland.

INTERNATIONAL SANITARY CONFERENCE AT VIENNA. An animated and interesting debate took place on the question 'Is man a vehicle for cholera, and can he carry it from one place to another?' Pettenkofer, of Munich, supported the view, founded, as he said, on his own observations and experiments, that cholera could be carried, not only by persons attacked, but by those who were unattacked, and in good health. He insisted above all on this point, that locality plays one of the most important parts. In support of his view he cited the cases of the towns of Munich, Spire, and Heilbronn, which were invaded by cholera last spring; it had not been proved that the cholera had been brought there. Dr. Drasche, of Vienna, maintained that the examples cited, in which it had not been proved that cholera had been carried, were not conclusive against the fact of introduction. As to the possibility of the disease being carried by persons in good health, there had hitherto been no observation which justified the assertion. M. Schleisner, of Denmark, expressed the same opinion. Dr. Zehender, of Switzerland, maintained also that the introduction of the disease could take place by means of infected persons, without it always being possible to obtain proof. The meeting was unanimous in replying in the affirmative to the question: If articles coming from infected places, and particularly those used by choleric patients, could carry or transmit cholera? There was more division of opinion on the question whether cholera could be transmitted by alimentary matters, and by live animals. The question relative to the transmissibility of the disease by the corpses of choleraic patients, was answered unanimously in the affirmative. The proposition that the disease might be propagated by means of the air was adopted with certain restrictions. The question relative to the duration of the time of incubation of the disease was much discussed. Finally, the majority concurred in the opinion expressed at the Conference at Constantinople, namely that there was a period of incubation which was relatively very short.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & CO., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & CO.—Calcutta: THACKER, SPINK & CO.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & CO.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & CO., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, AUGUST 5, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

THE INTERNATIONAL SANITARY CONFERENCE IN VIENNA.*

The sittings of the International Sanitary Conference held in Vienna commenced on July 1. The following were the members appointed as representatives of their various countries. *Austro-Hungary*: Baron von Gagnern; Dr. F. Ulrich, Councillor in the Ministry of the Interior; Ritter August von Alber, President of the Maritime Board at Trieste; Herr Haardt von Hartenthurn, Councillor in the Ministry of Commerce; Dr. A. Drasche, Physician to the Rudolf's Hospital; Professor C. L. Sigmund, of Vienna; Dr. L. Gross, Councillor in the Hungarian Ministry of the Interior; Herr H. Catinelli, Councillor in the Maritime Department at Fiume; Dr. J. Schlosser, *proto-medicus* in Hungary; Dr. N. Severinski, Regimental Surgeon in Croatia. *Belgium*: Dr. Henrard, Sanitary Inspector in the Ministry of the Interior. *Denmark*: Dr. P. A. Schleisner, Chief Physician in Copenhagen. *Egypt*: His Excellency Colucci Pacha, President, and Dr. Regnier, Secretary, of the General Council of Health. *England*: Dr. Dickson, Physician to the British Embassy in Constantinople; Dr. E. C. Seaton. *France*: Baron von Ring, Secretary to the French Embassy in Constantinople; Dr. Fauvel, General Inspector of the Sanitary Department. *Germany*: Dr. von Pettenkofer, of Munich; Dr. A. Hirsch, Professor in the University of Berlin. *Greece*: Dr. D. G. Orphanides, Professor in the University of Athens, and President of the Council of Health. *Holland*: Dr. H. L. Reeder, Marine Sanitary Officer, first class; Dr. H. von Kapelle. *Italy*: Dr. M. Semmola, Professor in the University of Naples. *Luxembourg*: Dr. Schmidt, President of the Natural History Society. *Norway*: Dr. J. Kjerulf, Chief of the Sanitary Board in Christiania. *Persia*: Dr. J. E. Polak (Hekim Baschi). *Portugal*: Dr. J. T. de Souza-Martins, Professor in the Medical School of Lisbon. *Roumania*: Dr. Marcovitz, member of the Superior Council of Health. *Russia*: Dr. E. Lenz; Dr. M. Kastorsky, physician to the Russian Embassy at Teheran. *Servia*: Dr. S. Miloshavlennitsch, chief of the Sanitary Department in the Ministry of the Interior. *Sweden*: Dr. N. J. Berlin, President of the College of Medicine. *Switzerland*: Dr. C. Zehender, District Physician in Zürich; Dr. A. Ziegler, Secretary of the College of Health in Bern. *Turkey*: Dr. Bartoletti, General Inspector of Health; Ali Bey, member of the Council of Health in Constantinople.

The first meeting was held on July 1, when Count Andrassy, Minister for Foreign Affairs, welcomed

the delegates in the name of the Emperor, and declared the Conference opened. Baron von Gagnern was chosen President, and Professor Pettenkofer, Dr. Fauvel, and Dr. Lenz, Vice-Presidents.

Professor Sigmund addressed the members of the Conference in the following terms.

‘In obedience to the call of our respective governments, we have assembled in Vienna, to consult together and arrive at conclusions on a matter deeply concerning the life and well-being of nations; on the establishment of uniform quarantine regulations, and the formation of an international commission on pestilential diseases. The pestilence, which in its periodical visitations during more than four decades has snatched away millions of men from countries in the most flourishing civilisation, which has thousandfold imperilled international intercourse, and which ever threatens to advance, was well fitted to induce the governments concerned to enter on a common course of action, in order to frame adequate and generally applicable regulations as to the means of warding it off. The views which have within the last few years become extensively diffused regarding the origin and spread of cholera, have led to the adoption of quarantine regulations, very various in kind, and in part contradictory of each other. We all know that very lately the doctrine of the communicability of cholera has become generally prevalent, and that, in consequence, numerous sanitary and quarantine rules, very various in kind, have been suddenly and quite independently introduced and carried into force in places where, shortly before, the utility of quarantine was altogether denied. While quarantine regulations are defended more or less warmly on humanitarian grounds, there must still be severe injury to commerce and intercourse from those newly instituted. Especially, in recent years, in the Red and Mediterranean, as well as in the Black and Adriatic Seas, and on the banks of the Lower Danube, at numerous stations of greater or less importance, numberless impediments to commerce have arisen, and have produced uncountable evils which, moreover, have in no case been counterbalanced by the advantage of preventing the spread of the disease. Most of the quarantine regulations, adopted or modified from the old regulations against plague, are in direct contradiction to the discoveries of science and experience, in open opposition to the prevailing tendency of the age. Not only concerning the more or less numerous impediments and interruptions of commerce, but especially concerning the very remarkable differences in quarantine regulations in the same districts of country and in certain ports, have well-founded complaints often been made in recent years; but almost in vain, for each individual Government upholds its regulations as in conformity with its own laws and suitable to local conditions. In the presence of such facts, it occurred to the Austro-Hungarian and Russian Governments to bring the question of cholera quarantine again under the consideration of an International Council. The programme laid before the Conference, as a guide to their proceedings, combines on the one hand the results of the Cholera Conference in Constantinople, and, on the other hand, the hitherto known facts and propositions, in order especially to obtain the conclusions of the Conference on two points, viz., first, the establishment of uniform quarantine regulations against cholera; and, secondly, the appointment of an international commission on pestilential diseases. With regard to

* From the *Allgemeine Wiener Medizinische Zeitung* and the *Allgemeine Medicinische Central-Zeitung*.

quarantine, the programme, without anticipating the opinions of the members, has, in the first place, assumed the protective power of quarantines and their continuance; but it has had only maritime quarantine especially in view, and, along with the lessening and simplifying of all sanitary measures, has especially put forward the question of uniformity. The idea of taking into consideration, as far as possible, the demands of humanity and of society, and of using quarantines simultaneously—at least partly—as stations for scientific observation, will also come under consideration. The proposal of an international commission on pestilential diseases rests on various grounds. In the discussion of technical questions points arise, for dealing with which sanitary and quarantine legislation still expects solid assistance from science. In the face of the international calamities which pestilences generally, and cholera in particular, have, like quarantine, brought on nations, the idea has rightly arisen, to form a central organ which, receiving material and moral aid from the governments, should concern itself with the establishment and guidance of the study of pestilential diseases on a determined plan and for a sufficient time, and which would at the same time serve as a skilled council on all international questions arising with reference to these diseases, especially with reference to quarantine. Against such dire enemies as epidemics and epizootic diseases, great measures of prevention may well be established. To promote these measures, to determine their nature, and to make them conducive to the common good of all, is not within the power of individuals, nor even of individual kingdoms. We are all acquainted with the labours of single experts and single corporations, which have been undertaken in this direction, and whose results have not been very satisfactory, principally because the labours have been undertaken with too little power, in too short a time, on too narrow a scale, without sufficient pecuniary aid, and carried on without a plan. Very recently the German Government has called into existence a state-commission, with a similar but limited object. The double object which the programme lays before the Conference affords material and opportunity for the most comprehensive conclusions; but I express the opinion of all the members, when I bespeak as conclusive and practical a treatment as possible of the questions.

A programme of twenty-six questions was submitted to the Conference, and discussed *seriatim*.

I.—Development and Spread of Cholera.

1. Is contagious (epidemic) cholera only developed spontaneously in India, and introduced always into foreign countries from without; or does it also occur endemically in countries beyond India, and in which?—Dr. Dickson (Constantinople) communicated the results of his observations on cholera in India. From statistic data he deduced evidence that there had not been a single case of cholera in Bombay this year; and, that the sanitary condition of India had been remarkably improved in consequence of the sanitary measures adopted by the Government. This did not prove that India was not the focus of cholera, but it showed how much the evil might be obviated by precautionary measures.—Dr. Hirsch (Berlin) defended the view that the starting-point of cholera was to be sought in India.—After some discussion, the Congress agreed in the opinion that cholera has an autochthonous character in no part of the world beyond India; that it has not become endemic in

Europe, but that the epidemics of the disease are to be regarded as having had their origin in India.

2. Is cholera spread by man?—A long debate took place on this question. Professor von Pettenkofer (Munich) was of opinion that cholera might be conveyed not only by the diseased but by the healthy. The nature of the locality played an important part in the spread of the disease. In the epidemic which prevailed last year in Munich, Spiers, and Heilbronn, no importation could be discovered.—Dr. Drasche (Austria) replied that the instances quoted in which importation could not be traced, did not prove that this did not take place. In thousands of cases the epidemic could be traced back to a certain diseased individual; when this was not the case, it arose from the investigation being rendered difficult or impossible through the complications of commerce. There was not a single observation which could bear scientific criticism, in favour of the communication of the disease through healthy individuals.—Dr. Schleisner expressed the same opinion, and supported it by the observations which he had made at numerous places on the coast.—Other members spoke to the same effect, and the Congress arrived at the general conclusion that cholera is communicated by human intercourse.

3. Can cholera be communicated by articles of ordinary use coming from infected places, especially those which cholera patients have worn?—This question was answered in the affirmative, without debate.

4. Can cholera be communicated by articles of food, or (5) by living animals?—These two questions gave rise to a long debate. Drs. Pettenkofer, Hirsch, and Zehender, gave affirmative answers; Dr. Dickson and Drasche denied or limited the possibility of cholera being spread in this way. The Congress finally concluded that these modes of communication were possible.

6. Can cholera be communicated by the transport of merchandise?—[This question was on the programme; but there is no statement as to the decision arrived at respecting it.]

7. Can cholera be communicated by the dead bodies of cholera-patients?—Dr. Polak communicated a telegram which he had received from the Persian minister for foreign affairs at Teheran, stating that in future the transport of the bodies of cholera-subjects to Kerbela (the place of pilgrimage) would not be allowed until they had been buried a year; and the burial-grounds must be outside the towns.—The question was unanimously answered in the affirmative.

8. Can cholera be carried to a distance by the atmospheric air alone?—The Conference accepted the decision of the Conference at Constantinople in 1866, that it is a law, to which hitherto no exception is known, that cholera never advances more rapidly than can be accounted for by the communication between one place and another. Hitherto, there has been a want of evidence in favour of the conveyance of the cholera-poison by the atmosphere.

9. Has the access of fresh air to the agent producing or spreading cholera any influence on its infectious property, or not?—This question was unanimously answered in the affirmative, in the sense of the conclusion arrived at by the Constantinople conference, that the choleraic principle very rapidly loses its deleterious action in fresh air; but that on the other hand, its power is maintained in activity for an unlimited time under certain special conditions of seclusion.

10. What is the length of the period of incubation in a case of cholera infection?

On this question a long discussion took place, which was begun by Dr. von Pettenkofer. He regarded it as not yet ripe for a positive reply, and said that therefore only an approximative determination of the period of incubation could be given. In his researches during the last epidemic of cholera in Munich he had found an average period of fourteen days; but the experience already attained was not sufficient to determine the maximum period of incubation, however desirable this might be.

Dr. Drasche said that, according to his observations of the cholera epidemic in Vienna in 1873, the average duration of the incubation in any locality was from eight to ten days. The period, however, approached that named by Pettenkofer, if the calculation were made from the day of death. The condition was otherwise when the day on which the disease appeared was made the base of the calculation.

Dr. Zehender spoke in favour of a much shorter incubation period as a general rule; there were, however, cases where incubation was of longer duration.—Dr. Dickson considered that the subject was not yet ripe for discussion.—Dr. Kjerulf believed that there was only a short incubation period, varying from two to five days.—Dr. Orphanides communicated the result of his observations in the Grecian islands, which tended to show that cholera had an incubation-period of from five to seven days.—Dr. Schleisner adduced several cases from his own observation, and spoke in favour of an incubation-period lasting three or four days.—Dr. Schmidt had seen a case in which the duration of incubation was eighteen days.—Dr. Berlin insisted on the difficulty of arriving at a decision, but maintained that the period was four days.—Drs. Semmola and Souza-Martins believed that the period of incubation was very short, and that it was dependent on the influence of climate.—The majority of the members adopted the opinion of the Conference at Constantinople, that the period of incubation was very short, rarely exceeding a few days.

11. Is a disinfecting agent or method known, by which the cholera-spreading agent can be rendered inert, or weakened? If there be such agent, what is it?—On the first part of this question, the Conference, after a long debate, arrived at the conclusion that as yet we know neither any agent nor means of disinfection, which destroys with certainty the cholera-germ adhering to man as object. The possibility, however, of discovering such an agent or method was not denied.—In regard to the question as to the power of any agent to weaken the cholera-poison, most of the members of the Conference spoke in the affirmative; and in this sense the utility of disinfection in combination with other sanitary measures was unanimously recognised.—The consideration of individual disinfecting agents was deferred, as it would again arise in the discussion of the twenty-second question of the programme.

(To be continued.)

LECTURE UPON THE GENERAL THERAPEUTICS OF THE NERVOUS SYSTEM. By E. C. SEGUIN, M.D.

(Concluded from page 468.)

CLASS C.

Tonics and Restoratives.

By restoratives I understand, with Headland, those remedies which restore to the system an element diminished by a disease, or whose diminution causes a disease. A few of this class are especially useful in diseases of the nervous system, two chiefly—phosphorus and fats.

I would not be willing to admit that there is any defined morbid state of the nervous system, which can be shown to depend upon a diminution of the phosphorus, which is so important an ingredient of nerve-tissue; yet I am the first to recognise that in some nervous diseases much phosphorus is excreted, and that in very many of them much benefit, even to a cure, is obtained by giving phosphorus. In practice the various phosphates, the acid phosphates, the hypophosphites, etc., if they do good, do so very slowly, and are hardly to be used in the treatment of serious cases, except as adjuvants. Phosphorus itself may be administered in the form of the official oil, or in the non-official solutions (Thompson's), and as phosphide of zinc. The dose of phosphorus ranges from $\frac{1}{40}$ to $\frac{1}{12}$ grain; that of zinc phosphide from $\frac{1}{6}$ grain to $\frac{1}{2}$ grain. In administering this powerful remedy, please bear in mind that some organisations are very susceptible to its toxic influence. In cerebral malnutrition, in neuralgia, in 'spinal irritation,' in hysteria, and in varieties of paralysis, this drug is of the highest value.

Fatty food and cod-liver oil are indicated in the conditions which demand phosphorus.

Among the tonics the chief are strychnia, arsenic, zinc, iron, quinia, and cold. Cold should, for its tonic effect, be applied only for a short period of time. This may be done by sponging, the shower-bath, cold compresses, the cold sheet, and sea-bathing.

A corresponding reaction follows, which consists in hyperæmia and improved nutrition. (*Vide infra*, counterirritants.)

We are unable exactly to explain why strychnia, or arsenic, or zinc should benefit the general nutrition, but daily experience teaches that these remedies are invaluable in many morbid states of the nervous system.

Strychnia, in cases of irritability, of hysteria, spinal irritation, and in some palsies, may be given in small doses for long periods of time; doses of $\frac{1}{40}$ grain or $\frac{1}{32}$ grain. The action of arsenic is often marvellous in chorea, and very satisfactory in other nervous diseases. Fowler's solution is the arsenical preparation most commonly employed, and in chorea it should be dealt out with no sparing hand; doses of $\mathfrak{m}\text{iv}$, $\mathfrak{m}\text{vi}$, or even $\mathfrak{m}\text{x}$ being well borne. The oxide and lactate of zinc have been much used in states of exhaustion of the nervous system, after sexual excess, or in chronic alcoholism, and in epilepsy. In the nervous states caused by alcohol, the zinc oxide proves almost as satisfactory as arsenic in chorea. I have usually employed it in combination with extract of nuxvomica. Since the introduction of bromide of potassium into general use, the zinc treatment of epilepsy has fallen into (perhaps unmerited) disuse.

M. PASTEUR, the eminent professor of chemistry in the College of France, has been obliged to resign his chair in consequence of failure of vision. The French National Assembly has granted him an annual pension of 12,000 francs (480*l.*), with remainder of one-half to his widow.

Quinia, in moderate doses, would seem to act as a tonic. It is possible that it does so by causing more food to be taken and digested, yet, from the immediate improvement in well-being and in cerebral activity, which many experience while taking it, I am inclined to the opinion that this remedy does exert a direct effect (restorative?) upon the nervous centres.

Iron I have not spoken of, because it does not especially affect the nervous system. It improves the condition of the blood, and, by so doing, cures morbid states of the nervous system (neuralgia), which depend upon anæmia or chlorosis.

Perhaps it were well that I should here speak of two so-called specific modes of medication, very useful in nervous diseases, and which would otherwise not enter the classification offered you. I refer to the treatment of constitutional syphilis, which often gives rise to morbid states of the nervous system. Nearly all of these morbid states are a part and parcel of the third (tertiary) stage of syphilis, depending upon affections of fibrous tissues of bones, of blood-vessels, and upon the presence of gummata in the nervous centres. I would only speak of one point in connection with this subject, and that is the necessity of using the iodide of potassium in really effectual doses, giving from ʒj to ʒvj a day, until improvement takes place. You will be surprised to see how a patient with tertiary syphilis will gain while taking ʒss of iodide of potassium in the twenty-four hours, after having resisted smaller doses. No unpleasant symptoms attend the taking of large doses, provided that restoratives and good food be also given.

The other specific medication is the treatment of malaria in its original form by quinia. Malarial neuralgia is a well-known and an obstinate affection. It may be cured by quinia in the usual way; but a much more rapid removal of the disease is obtained by using the quinia in the shape of hypodermic injections over the affected nerve. We then obtain the specific effect of quinia on the nervous centre and counterirritation on the nerve. Nearly seven years ago* I published the results of my experience with this medication in the New York Hospital, giving full details of the practice. As a general rule, in nervous disorders dependent upon malaria, do not err by giving too little quinia.

CLASS D.

Counterirritants.

By counterirritation is understood a localised irritation, which modifies the nutrition or mode of activity of another part than that irritated, either just beneath it or at a distance from it. Counterirritants almost always act through the spinal cord, and their mode of action is typified by a morbid process which takes place as a consequence of severe burns. If a limb or part of the body be scalded or charred, the patient is not in danger merely because of the shock of the injury, or of the exhausting discharge accompanying the healing of the burn, or of the pyæmia which may take place during the continuance of this suppuration, but he is also likely to suffer from certain visceral complications which occur in parts bearing a definite relation to the burn. Brown-Séquard demonstrated many years ago that on cutting

across the spinal cord, above the origin of nerves going to the burnt part, no visceral lesions occurred; thus proving that these lesions were set up by a morbid state of the spinal cord produced by the burn. The burn corresponds to our counterirritation, and the altered nutrition of the viscera to the distant effect produced. In the one case a morbid process is induced; in the other a beneficial change, not yet understood by us, is determined.

The alternate application of cold and heat does much to improve the nutrition of paralysed parts, and is used for many special purposes.

Brown-Séquard has recommended the use of these means to prevent the formation of bed-sores, and to heal those which may be already formed. The method consists in applying an ice or snow poultice over the part for five or ten minutes, following this by the immediate application of a hot poultice. This should be done once a day over the parts threatened with the formation of bed-sores. When the same thing is done twice a day to sores already formed, as a rule, sloughs come away, circulation is improved, and granulations will soon spring up. I have seen huge bed-sores healing under this treatment while the patient was failing.

The actual cautery is a means of the utmost value in the treatment of nervous affections. It is one, however, which has fallen into very great disrepute, in consequence of the manner in which it was formerly employed. A burn, sufficient to produce suppuration, is not necessary, surface-irritation being what we seek to produce.

The theoretical view that surface-irritation is most useful has, like several others brought forward in this lecture, a true physiological basis. It rests upon the well-known law that the terminal nervous twigs and their special terminal bodies are more irritable than nerve-trunks.

Brown-Séquard has revived the use of the actual cautery; and by means of his form of cautery we are enabled to produce much skin-irritation, with little pain to the patient, and no subsequent annoyance from sore surfaces.

The cauterising iron which he employs is tipped with platinum. The platinum never gets rough by ordinary heat, as does iron, and there is, consequently, a smooth surface to come in contact with the skin every time the cautery is used.

The white heat is necessary in using the actual cautery, because it produces the maximum degree of irritation to the nerve with a minimum of pain.

The cautery thus heated (in a coal-fire) should be rapidly drawn over the part selected, four or more strokes, of from one to six inches in length, being made. This can be done in a very few seconds, and in many cases no real pain is experienced by the patient. The strokes remain as reddish-brown welts, which are quickly surrounded by a zone of hyperæmia, which is sometimes immense. A moderate degree of burning pain is felt for twenty minutes or two hours after the application. Sores never result from the burning, and not once in twenty strokes have I ever seen blisters arise. The epidermis is cast off dry in a few days, leaving a brownish stain, which passes off wholly in a short time. The cautery can be used upon the face with perfect safety. I have made use of this most valuable means in women, and children thirteen years old, without anæsthetics. The disagreeable ideas connected with the words 'burning' and 'cautery,' in the minds of physicians and of

* 'On the Subcutaneous Use of Sulphate of Quinia in Cases of Malarial Neuralgia.'—*New York Medical Journal*, 1867, p. 402.

patients, the barrier to the more general use of the platinum cautery.

Setons have so much gone out of fashion that I need hardly stop to enter a protest against their use. It is very doubtful if a suppurating sore produces more irritation than the cautery or blisters, and there are grave objections to using setons.

Blisters are invaluable means of producing counter-irritation. Let me ask you to use them in such a way as not to produce suppuration; repeat the blisters and heal the blebs as soon as possible. Great good is often obtained from a series of small blisters.

Dry cupping is beneficial in many spinal affections. The number of cups applied should be large—from ten to twenty. It is not necessary to use the cups immediately over the seat of the disease. Ten cups may be applied upon the back, and ten in front, with the same benefit as if all were applied behind.

It is a matter of doubt whether wet cups act better than, or in a different manner from, the dry. The degree of skin irritation produced by the process of wet cupping is certainly very much greater than in that of dry cupping; and it cannot be positively denied that the loss of blood is useful. In various inflammatory affections of the cerebral and spinal meninges, and in some functional disorders, wet cups are still used.

Sulphur-baths do good by the irritation they produce upon the surface, rather than from any effect of the sulphur upon the system generally. These baths may be employed liquid or in the shape of vapour. For liquid sulphur-baths the sulphuret of potassium is dissolved in water, and the patient soaks himself awhile in the solution. A better application is obtained by vapourising sulphur in a chamber into which steam is let in, the patient's head being kept out of the bath, of course. A stay of ten or twenty minutes in this atmosphere produces a great deal of cutaneous irritation, which, in time, leads to a decided desquamation. Some of the natural sulphur-spring waters are also used for bathing purposes, but are much less effectual. In spinal diseases, particularly posterior spinal sclerosis (locomotor ataxia), series of such baths have done great good. They are also useful in lead-poisoning. Many medicated baths likewise act by producing extensive irritation of the skin.

CLASS E.

Electricity.

We employ all three forms of electricity in medicine, Franklinism or static electricity, galvanism (or voltaic electricity), and Faradism or induction electricity. Any one of these forms may be used in the treatment of diseases of the nervous system in a rational or an empirical way.

The rational applications of electricity are to produce muscular contraction (passive exercises) and to affect the nerves of sensation (irritation, sedation).

What I may call the empirical use of electricity is when we attempt, by means of it, to modify the mode of activity of deeply placed organs, such as the brain, spinal cord, and the ganglia of the sympathetic.

It would be out of place for me to attempt, in a few words, to speak of the special application of electricity. A great deal has been written about this matter in the last few years, and I am glad to say that there are a few small books on the subject which I would urge you to study. I need only say that within certain limits, corresponding with our physio-

logical knowledge, I have the greatest faith in the power of Faradism and galvanism as remedial agents, and that I use them a good deal.

CLASS F.

Hygienic Means, etc.

The cases of nervous disease which are strictly speaking active, due to hyperæmia, or over-action of the nervous centres, I regard as being exceedingly rare. Consequently, I regard the immense majority of cases as requiring a supporting diet and such hygiene as shall tend to improve nutrition.

There are very many points to be considered in this connection.

In the first place, many paralytics suffer from slow digestion and constipation. The diet of such patients should consist of such articles of food as leave little detritus, as meats, fish, eggs, milk, and fats. Vegetables and starchy or sweet articles should be allowed sparingly.

In the second place, the bladder in many cases (spinal palsies) requires to be emptied by means of the catheter. In such cases you cannot exercise too much gentleness and care in introducing the instrument, for fear of setting up cystitis, or of aggravating one already present.

Thirdly: In many spinal cases there is immensely exaggerated reflex activity of the spinal centres; spinal epilepsy is set up by the contact of the bed-clothes, your hand, etc., with the palsied limbs; and an overloaded bowel brings about attacks which seem spontaneous. By strict orders to the nurse, and by the help of mechanical contrivance, you can reduce these spasms to a minimum. If one occur, recollect that you can stop it by forcibly flexing one or both great toes, as indicated by Brown-Séquard.

Fourthly: I would ask you always to bear in mind that bedridden paralytics are peculiarly liable to fatal attacks of bronchitis, broncho-pneumonia, and pneumonic phthisis. Remembering this, you will give directions to obviate all that which might expose your patients to such chest complications.

Fifthly: Inasmuch as bed-sores are likely to occur among the complications of nervous diseases, a few words may be added to what has already been said concerning their prophylaxis.

It is important to make every piece of clothing beneath the patient smooth. Consequently, a pretty hard mattress or water-bed is the best for them to lie upon. Special care is to be taken that the under-sheet does not get wrinkled and drawn into folds; its ends may be fastened down by tapes. The shirt worn by the patient should be kept smooth under him, and perfect cleanliness must be enforced. Special attention to these apparently small matters will in most cases be sufficient to prevent the formation of eschars.

In case a bed-sore has formed, the best course to pursue is to clean away all necrosed skin and connective tissue (tow-like shreds) by means of forceps and scissors, and then to use the ice and poultice treatment as above detailed. When healthy granulations spring up ice poultices are still useful once or twice a day, to be succeeded by ointments or adhesive plaster strapping.

Sixthly: In the matter of coffee, alcoholic drinks, and tobacco; you will hear physicians asking their patients to give up the use of these articles, simply because they have a disease of the nervous system. I am afraid, gentlemen, that this is very illogical. For

my own part, I do not proscribe these luxuries unless there is evidence that their use has had something to do with the development of the morbid state. Usually I do not at all interfere with the use of coffee, and ask that a less quantity of alcoholic drinks and tobacco should be used. The worry and nervousness consequent upon the giving up of an established habit is worse for the patient, in my opinion, than the moderate use of the above-named articles.

Let me close this rather fragmentary lecture by calling your attention to something which is not wholly extra-medical. I allude to the care of your patients' spirits—their emotions and fancies, if you will. Never let *alarm* be one of your medicaments. If necessary, in order to bring about the reform of bad habits, lay the picture of consequences before your patient truthfully, but not in the language of exaggeration. Even in hysterical cases you need not be so frank as to hurt your patient's feelings: it will often do if her relatives know precisely what you think of the value of the symptoms. In cases of mental disorder pray do not forget that even very maniacal or melancholic patients attend to and remember all your words and actions, and will treasure any kind and careful behaviour of yours, as well as bitterly recall any unkind or hasty phrases and acts. As a general therapeutic rule, I would have you be as anxious to avoid wounding the sensibilities of your poor or wealthy patients as of injuring their tissues.

BUHL, HERING, AND FRIEDLÄNDER ON PHTHISIS, TUBERCULOSIS, AND INFLAMMATIONS OF THE LUNG.*

(Concluded from page 462.)

C. Friedländer's first work on our list is small but good. Its experiments are chiefly on the results of section of the vagus, recommended by Traube, and the inflammations of the lung thus set up have been studied by Friedländer microscopically. Simultaneously, some valuable observations on the epithelium of healthy lungs are made public. He points out with great force that the air-cells possess, not a mere broken and irregular lining of cells, but as Chrzonszczewsky and others agree, a continuous and regular epithelium. However he contradicts Buhl, who regarded this as like the epithelium of a lymph-vessel. These pale, polygonal flattened cells become granular and opaque (cloudy swelling) in the first stages of inflammation (*engouement*). The same occurred in the oedema of the lung, which our experimenter brought about by his nerve-sections; and may it be shown even in healthy lungs, if they

be saddened in serum or watery fluid before examination. Hence Friedländer concludes that even in inflammation this cloudy swelling of the alveolar epithelium is a passive process, brought about by the abundance of the fluid with which the cells are moistened; since, besides hyperæmia, there is a simultaneous exudation of blood-stained serum in the air-cells. The cloudy, swollen epithelial scales, which generally, and he thinks normally, contain more than one nucleus, almost entirely desquamate, and furnish one constituent of the alveolar exudation. In the further course of the inflammation, he observed a striking increase in the number of white blood-corpuscles in the smaller vessels of the air-cells. Next, numerous lymphoid corpuscles (*Zellen*) make their appearance in the interstitial connective tissue, and finally one sees even the lumen (interior) of the air-cells filled with them—indeed they then constitute the bulk of the solid contents. Cohnheim's theory of the migration of white blood-corpuscles offers a ready explanation of this. Friedländer very often observed small lymphoid corpuscles in the epithelial cells, and verified protoplasmic movements in them. It is true he has only made accurate observations as regards this point in animals. As regards pneumonia induced experimentally, Traube explains it by the passage of fluids from the mouth into the bronchi, through section of the vagus; but he believes that human catarrhal pneumonia admits a similar explanation. On this point Buhl and Friedländer contradict one another; the former, not believing in a true epithelium of the air-cells, denies that they can be affected with catarrh, and considers the secretion to be partly desquamated endothelium, and partly sucked in bronchial secretions. But we must consider Buhl's theoretical objections as swept away by Friedländer, who has afforded direct proofs that primary products of inflammation may occur in the air-cells (alveoli) in the form of lymphoid corpuscles (*Zellen*), as extravasated or extruded (*ausgewanderte*) white blood-corpuscles, quite independently of the bronchi, and irrespective of desquamated epithelium. Friedländer's observations also make an active participation of the epithelium in the increased cell-formation more than doubtful; and the desquamation sinks down into a purely passive act in most forms of inflammation, as even Buhl himself admits. Hence our objections to some of Buhl's views are confirmed.

Waldenburg regrets that Friedländer's second work on local tuberculosis is not equal in value to the one just noticed. He does not doubt the premises, or the theories with which Friedländer sets out; but he doubts his conclusions. Friedländer starts with Virchow's definition of tubercles, but amends this according to Langhans, Schüppel, Köster, and to some extent Rindfleisch and others, and finally throws overboard not only Virchow's doctrines, but almost the whole foundation of our ideas on tubercles. The mischief is wrought by the giant-cells, long since known under the name of *myéloplagues* (Robin), [see Rindfleisch's *Pathological Histology*, vol. i. p. 72, Dr. Baxter's transl. New Sydenham Society], and already described by Virchow as one of the constituents of tubercle, although not recognised by him any more than by many other eminent pathologists as really pathognomonic of tubercle; although Friedländer says that Langhaus deserves the credit of discovering that they are so, this author stating that 'Langhaus pointed out their peripheral situation, the equal size and radiating arrangement of their nuclei, characterising

them as formations *sui generis*.' Friedländer quite forgets that these giant-cells are by no means constant, whilst they have been found in other pathological formations, as for instance, in the neuroma nervi optici of Hering. Virchow's warnings are all disregarded. For certain histologists, the giant-cells remain specific elements of tubercle. 'All this,' says Waldenburg, 'reminds one sadly of the history of the so-called "tubercle-corpuscles" of an earlier date; history which seems repeating itself in another form.' Friedländer takes his stand on this, as we think, erroneous point of view; whilst admitting that he cannot always find giant-cells in tubercles, yet he declares these to be pathognomonic, and boldly calls all that contains them tubercle, denying the name to all in which they are wanting. In this sense, since Köster's discovery, we must reckon as tubercles the granulations of inflamed joints, including white swellings; or with Schüppel, the nodules (only seen by the microscope) in scrofulous, apparently purely hyperplastic, caseified lymphatic glands; next, as Friedländer discovered, nodules in scrofulous abscesses of the skin, in ulcers, and even in caries, still more in lupus, which is for the most part composed of small nodules of tubercles tightly pressed together, often confluent with giant-cells and epithelial elements—in short, the typical build of tubercle. Köster also vouches for the occurrence of miliary tubercles in caries and in ulcers, not merely in scrofulous sores, but in syphilitic chancres also; but he maintains their occurrence in unhealthy granulations to be consecutive or secondary, a view which seems highly probable. Friedländer, however, will have that they occur directly in healthy tissues. Hering showed before Friedländer that giant-cells occur in lupus, but did not consider them diagnostic of tubercle. However, the latter's observations are very interesting. He 'found, in the floor of a shallow ulcer, near the os uteri externum, a copious eruption (*sic*) of tubercles with giant-cells.' A second case was in a swelling, of the size of a hazel-nut, in the lobule of a lady's ear, who was otherwise healthy; it was almost entirely composed of tubercles. He found tubercles also in a rodent ulcer of the cheek, as well as in the walls of an epithelial cyst of the breast. He notes also 'the very interesting occurrence of tubercles in the stroma of a cancerous tumour, which had originated in the cicatrix of a rodent ulcer.' All these, with full faith in his giant-cells, he does not hesitate to call tubercles. Yet, faulty as we think this reasoning, and mistaken as may be his nomenclature, science has yet much to gain from Friedländer's investigations. His facts will remain, when the erroneous and puzzling terminology he adopts is quite exploded. Meanwhile, we protest against burdening our memories or our text-books with fresh definitions of tubercle. It were better to throw the old names overboard, and start afresh, than to give them dubious or double meanings. This much may be gained, even if Hering's view that giant-cells are cut lymphatics gain acceptance, that all new formations in which giant-cells occur will have this in common, that the new tissues take their origin from the lymphatic vessels. This will not, however, make them identical in nature, and, according to their locality, just like tubercles, they may or may not rejoice in giant-cells. All this is, of course, merely illustrative of an hypothesis. These questions must, however, be diligently investigated. Giant-cells especially must be closely looked after. Lang-

hans and Friedländer talk of 'a broad, strong mantle-like veil,' sometimes found enveloping the giant-cells; and the temptation to lift the veil is a strong one.

[The translator has thought it best to add only a few words of explanation to this very careful *résumé* of recent works. It seems to him that British anatomists and British pathologists have not been one whit behind either France or Germany, as regards the lung or lung-diseases. Compare especially the account of the normal structure of the lung, by Drs. H. Davies and Andrew Clark, in the former's work on *Diseases of the Heart and Lungs*; the works of Dr. Addison (New Sydenham Society); and the more recent publications of Drs. Wilson, Fox, Andrew Clark, Burdon Sanderson, H. G. Sutton, Waters, and many others, too numerous to mention.—*Rep.*]

W. BATHURST WOODMAN, M.D.

MAREY ON NEW EXPERIMENTS ON HUMAN LOCOMOTION.*

The brothers Weber supposed that, in human walking, the oscillation of the shifting leg was due to gravity, the foot performing a pendulum movement.

This view long prevailed in physiology, but it has been opposed, in recent years, by arguments of various kinds. It was M. Duchenne (of Boulogne) who first showed that the leg is not quite passive in its displacement, for certain muscular paralyses prevent the oscillation. M. Giraud-Teulon has attacked Weber's theory, by showing the mathematical errors on which it rests. Lastly, M. Carlet has, by experiments, determined the active rôle of certain muscles in the displacement of the leg in walking.

If gravity do not act alone in the oscillation of the leg, it becomes impossible to foresee what movement will result from its combination with the action of the muscles. M. Marey (*Comptes Rendus*) sought from the graphic method an experimental solution of this question.

When a body moves in a straight line, with velocities varying every instant, it is easy to record the nature of its movement, if the space past over be not very great. When the body is connected, by a rigid wire, with a style applied to a rotating blackened cylinder, the style being carried parallel to the axis of the cylinder, with variable velocities, will give sinuous curves, each element of which will indicate, by its inclination, the velocity of the movement which produced it.

But the movements in walking are too extensive to be inscribed according to their real size. To reduce them, without altering their characters, M. Marey used an apparatus of wheelwork. In this apparatus, each of the moving parts catching into another which had ten times more teeth, it followed that the movement communicated to the first axis must be reproduced by the second with a reduction of $\frac{1}{10}$; the third axis reduced the movement $\frac{1}{100}$, the fourth $\frac{1}{1000}$, etc.

If the foot be attached to a thread passing round a pulley borne by the first axis of the counter, while on the third axis is another pulley, the thread of which actuates the style, traces are obtained, in which the space traversed by the foot is reduced to a hundredth of its real extent.

Fig. 1 shows five traces got from paces of unequal velocity. A corresponds to the quickest walk, C to

* Abstract from *Comptes Rendus*.

the slowest. The abscissæ correspond to times, the ordinates to spaces passed over. A chronograph CH writing $\frac{1}{10}$ of a second, allows the measuring the elements of the curve, while the spaces passed over, reduced by the instrument, give one centimètre of trace for one metre of ground traversed.

1. *Velocity of Pace.* This is expressed by the general inclination of the curve, or by the relation between ordinates and abscissæ. As the different traces in the figure correspond to the same space (3.50 mètres) passed over in different times, it is the relation of the time taken to pass over it which will show the velocity of the different paces. If we count, with the aid of the chronograph, the time elapsing between the commencement of each curve and its point of arrival projected on the axis of x , we shall have the measure of this time. Thus, for the slow walk 1 to A we count 13 seconds;] for

the faster walk, 2 to B, $6\frac{1}{2}$; for the walk 5 to C, only 2 seconds.

2. *Alternation of Rest and Movement of the Foot.* Evidently, where the curves show a horizontal line, this corresponds to the application of foot to ground, and its immobility. The duration of these applications is seen to decrease as the pace is accelerated. The time during which the foot is displaced is shown by an oblique line, the projection of which on the ordinates grows as the pace is accelerated. This shows that the length of the step increases in proportion to the velocity of pace.

3. *Nature of the Foot's Movement of Translation.* This movement is represented almost throughout by a straight line; it is, then, uniform in nearly its whole duration. The inflexions of the line at beginning and end indicate that, in rapid paces especially, the movement of the foot commences and terminates

FIG. 1.

FIG. 2.

with short periods of variable velocity. It is seen how the oscillation of the leg is quite unlike that of a pendulum.

But it is not necessary to attribute exclusively to the action of the muscles of the leg this uniformity in transport of the foot. We know, in fact, that two distinct causes intervene in this transport:

1. The angular movement which the leg executes about the pelvis;
2. The horizontal transport of the pelvis itself; that is to say, of the point of suspension of the leg while it oscillates.

We may understand how, by the combination of these two influences, the movement of the foot tends to uniformity. This will occur if the minima of velocity of the first kind of movement correspond to the maxima of the second. It thus became very interesting to determine what is the movement of translation of the trunk in different paces.

The above-described apparatus served for this. A cord attached to the waist transmitted the movement of transport of the trunk. From various paces the following figures were obtained (Fig. 2), the analysis of which gives some interesting results.

The undulations are much greater in the cases of very slow walk than in those of a more rapid one. Thus the movement of translation of the body is ununiformed by its velocity. The inverse effect occurs in the vertical oscillations of the body, which increase in proportion to the velocity of progression and the length of the step.

The number of jerks (*saccades*) is double that of the movements of a single foot in Fig. 1. This is readily understood, since the two feet, repeating the same acts, come by turns to impress on the body a new impulsion.

To explain this action M. Marey has traced, parallel to the line 2, the curves P of the movements

of the right foot and the left foot. These curves (the one a dotted the other a plain line) are easily recognised as similar to the line 2 B, Fig. 1. Lastly, observing the superposition of the different parts of these curves with the undulations of the curves of translation, it is seen that the body receives a surplus of velocity about the middle of application of each foot. This fact accords with results of experiments formerly published by him.

M. Marey adds, in closing, that one of the most important features of these studies is the notion which they give of the variability of the movement of translation of the body in walking or running.

M. Marey intends in another note to show the application which may be deduced from these studies for the better utilisation of the work of animate motors.

ALEX. B. MACDOWALL.

PATHOLOGY.

MAGNAN AND MIERZEJEWSKY ON LESIONS OF THE VENTRICULAR WALLS IN GENERAL PARALYSIS.—MM. Magnan and Mierzejewsky, struck with the lesions of the membranes and cortical substance which they had observed in previous investigations upon the pathology of general paralysis, have still more closely examined the lesions of the surface of the brain, and conclude that these alterations should be regarded as the anatomical cause of the malady; in fact, agreeing with Bayle, who regarded it as a chronic meningitis; with Calmeil, who designated the affection chronic diffused periencephalitis; and with Parchappe, who terms it general cortical cerebritis. The condition of the ependyma had not escaped the attention of other authors, who have pointed out the granular condition of the fourth and lateral ventricles, not only in this affection but also in chronic hydrocephalus, chronic alcoholism, senile dementia, softening, etc. The intimate relation, however, of the ventricular lesions to those of the surface of the brain had not been established. It is the association of these, the authors observe, that constitutes the essential characters of general paralysis—*l'encephalite interstitielle diffuse généralisée*. Nine cases (six males and three females) of general paralysis, studied more particularly from the point of view of the ventricular lesions, form the basis of the present communication. Of the women, one was also ataxic, the others epileptic. In five of the males the posterior columns of the spinal cord had undergone degeneration. In all nine, the walls of the ventricles were the seat of granulations, varying in volume and number. They had the form of small rounded, greyish, gelatinous eminences like grains of semolina. They were more numerous in the posterior portion of the floor of the third ventricle, giving to this part somewhat the aspect of a cat's tongue. The ependyma was thickened by these granulations. Sections through these showed greyish bands extending into adjacent structures.

Microscopically examined, these granulations were seen to consist of connective tissue, true fibromata, the source of which was the reticular layer of the ependyma. This, as the result of irritation, becomes the seat of an exuberant proliferation, budding and raising the epithelial layer, which yields to the pressure, gives passage to the connective tissue, whence result the numerous papillæ of the surface.

One of these minute fibromata divided vertically shows a band of closely reticulated tissue on the surface with scanty slender long nuclei, forming a kind of shell, or hull, from the inner surface of which are given off numerous fibres passing inwards. The fibrous band that encloses the tumour is continuous with the reticulated layer of the ependyma, and divides into two layers, which enclose the papillæ. Where these papillæ occur in the neighbourhood of a commissure or canal, e.g. the aquæductus Silvii, they obliterate the cavity.

The reticular layer of the ependyma, the principal seat of the chronic irritation, not only sends its budding papillæ outwards towards the surface, but also sends fibrous roots internally into the neuroglia of the nerve-tissue. The nuclear proliferation of their connection is most abundant in the vicinity of vessels.

The same diffused chronic inflammation is found also in the spinal cord. The chronic irritation of the peripheral aspect of the cerebrum and its ventricular cavities, diffused extensively in all directions, demonstrate that general paralysis is essentially a diffused interstitial encephalitis, and that, if these characters are more pronounced in some parts than in others, it is that it finds in these parts the more favourable elements for chronic inflammation, viz., the cellular tissue and abundant vascularity.

[In acknowledging the value of the above contribution to pathological science, we confess that it is possible that in England we have of late overlooked somewhat the part that is taken by the membranes in the pathology of general paralysis, and that, in looking to lesions of the vessels and neuroglia for its morbid conditions, we have not included the whole of its pathological history. It is only fair, however, to remind our readers that the existence of these papillæ in the ventricles has often been recorded by British observers; even before the days of microscopical research it was noticed as 'miliary meningitis.'—*Rep.*]

W. B. KESTIVEN.

RICHEL ON APHASIA.—From an instructive paper on aphasia, in the *Revue des Deux Mondes*, by M. Ch. Richet, we take the following remarks.

It is probable that, between the organ of thought and the vocal organ, there is a third, the organ of speech (*parole*); it is the lesion of this which constitutes aphasia. Certain authors, however, have held that aphasia does not exist; that the case is sometimes that of a loss of memory, sometimes that of destruction of the intellect. It is fitting that we should examine these two objections (though the problems relate rather to psychology than to physiology).

In the memorable discussion which took place in the Academy of Medicine, M. Piorry affirmed that aphasia was merely *verbal amnesia*; and so it was useless to make the faculty of language something special. It appears, however, that memory itself is not a faculty which can be distinctly defined. One cannot conceive a thinking being who has no memory; it is the basis of all our actions, and, above all, of our ideas; whenever the mind thinks it makes use of anterior thoughts, and cannot separate itself from them. We identify ourselves, so to speak, with the notions we have acquired, and to separate the memory from the intellect can only be an analytic process, excellent for study, but impossible to accomplish in reality. It might be said, then, that there are different memories, applying to all the objects that

we know, but that there is not a single memory. We see, indeed, that nothing is more capricious than memory. It is a common fact that each individual, according to his aptitude, retains certain things much more easily than others. One can recall verse, who is unable to retain prose; another will have the memory of figures, another, that of places; and yet we should not make, for figures, places, verse or prose, a special faculty. It is quite otherwise with language, and if language be a memory, it is a memory so special, and has reached such a development in the life of individuals and the history of humanity, that it does not seem legitimate to confound it with other memories. For the rest, we find, from a study of aphasia, that it is produced specially; the aphasic play at chess and at cards, are interested in their affairs, understand them, discuss them, after their own manner, by multiplied forms of gesture, and a mimic language which they vary extensively. It is of little consequence if you call aphasia verbal amnesia; it would be sufficient to recognise that the verbal memory is a particular faculty, capable of being injured while the other faculties remain intact. But we will not even make this concession to the opinion of M. Piorry. Do we not see that the aphasic person who incessantly repeats *cousin*, and cannot say either *cou* or *sisi* separately, has lost something else than memory? The aphasic woman who said '*Bonjour, monsieur*,' every second, could never say '*Monsieur, bonjour*'; yet she retained the memory of the two words.

It is not necessary, indeed, to believe that all the faculties of the intellect are continually submitted to the will. There is a certain amount of *automatism*, more or less similar to what the physiologists of our age have called *reflex action*. We may, from the theoretical point of view, consider the nervous system as constituted of a sensitive cell, into which enters a sensitive nerve, and which is connected with a motor cell, whence issues a motor nerve. When the sensitive nerve is excited, by pinching or the like, the excitation is transmitted to the motor cell which makes a muscle contract, by means of the motor nerve. In this case will, intelligence, consciousness have no part in the production of the motion, it is a fatal, unreflecting action. . . . It is by reflex action that all those automatic and involuntary actions can be produced, that form three-fourths of human life. Thus when we take a walk we may think of anything else. Our intellect is not distracted by the movements we make, nor occupied with willing to walk. We are in this respect veritable automata; the step we take provokes a second step, and reflection does not act. M. Onimus has rightly compared language to the automatic functions of walking, of dancing, of playing on instruments. Certain observations of aphasia are very interesting from this point of view. A patient to whom some one had said 'How does that do?' replied, 'It does very well.' A few seconds afterwards he could not repeat this phrase. In such cases the patients speak quickly, as if they were afraid of forgetting.

From these examples we see that there are in language various elements; the memory of words, the arrangement of phrases, and that automatic part which permits of our speaking without effort. There is a fourth element which has considerable importance; I mean the intellect. It is impossible to regard aphasia as a total disturbance of the intellect; that is not destroyed when the faculty of language is abolished. A musician, having become aphasic, may

write the notes of an air which he has heard sung. It is true, he may not be able to write a single syllable, yet he will write the music as if he were quite without disease. Can any maintain that the intellect of the man is destroyed?

Still, it must be admitted that the intellect, in the aphasic, is often gravely affected. Professor Rostan could no longer comprehend the *Entretiens littéraires* of Lamartine, and Lordat suffered all his life from the lesion of his intellectual region. From having been an orator and improvisator of the first order, he became, after his temporary aphasia, incapable of speaking in public. He read his lectures, and could no longer improvise. Nearly all the aphasic are weak-minded; they have ideas more or less infantile; the merest trifles make them laugh or cry. Material concerns, their meals, and their sleep, interest them before anything.

PICOT ON THE ACTION OF WATER INJECTED INTO THE VEINS, WITH REFERENCE TO URÆMIA.—Traube, seeking to explain the phenomena of poisoning called uræmic, attributed them to the fluidity of the blood, and the great tension of the aortic system, producing œdema and anæmia of the brain. M. Picot has recently (*Comptes Rendus*, July 6) described to the Paris Academy some new experiments on this subject. They were made on rabbits and dogs.

The following are his conclusions.

1. Injection of water into the jugular vein, in a dose of one-thirtieth to one-fiftieth of the weight of the body, kills rabbits.

2. It is necessary with these animals to increase the dose to one-tenth, if the injection be made by the external saphenic vein.

3. Doses of water, up to one-eighth of the weight of the body, injected either into the peritoneum or into the veins, will not kill dogs; at one-fifth, death occurred from hæmorrhagic rupture, but in none of the animals experimented with, where death was produced, was there observed anything similar to the phenomena of uræmia.

4. Water injected into the blood (as Richardson has already observed) acts on the red corpuscles, altering their structure, and in all probability, rendering them unfit for gaseous exchanges. The absence of encephalic lesions is against the idea of death by the nervous system.

5. It is probable that in animals submitted to injections into the jugular, death occurs from a profound difficulty in respiration, occasioned by the sudden and prolonged entrance, into the pulmonary system, of blood charged with too great a proportion of water.

6. If we consider that a dog in twenty-four hours excretes only twenty-two cubic centimètres of urine per kilogramme of its weight, and that, in the experiments there was injected as much as 100 or 125 cubic centimètres of water per kilogramme, one can understand how difficult it is to suppose that the pathogenic cause of uræmia is the exaltation of intravascular pressure, under the influence of suppression of urine, leading to œdema and anæmia of the brain.

7. The doctrine of Traube, accordingly, does not appear to be the right expression of the pathological phenomena.

ALEX. B. MACDOWALL.

CAZENEUVE AND DAREMBERG ON THE CONTENTS OF SPERMATIC CYSTS.—In the July-August

number (p. 447) of *Robin's Journal de l'Anatomie et de la Physiologie* appears a note by the two above-named authors 'On the Nature of the Liquid contained in Spermatic Cysts.' The observations were made upon the contents of three cysts which had been punctured in La Charité. In the sediment separated by filtration numerous spermatozoa were discovered, some of which retained their vitality for twelve hours after the fluid had been drawn off. The reaction of the liquid was feebly alkaline.

The two most important facts elicited by the analysis of the filtrate were: 1. The presence of a considerable quantity of chloride of sodium—a salt of which only the most infinitesimal traces are present in normal spermatic fluid; 2. The absence, on the other hand, of phosphates—spermatic fluid, containing, as a rule, a proportion of phosphate of magnesia.

J. C. GALTON.

SURGERY.

KLEINSCHMIDT ON THE TREATMENT OF SNAKE-BITES WITH STRONG LIQUOR AMMONIÆ.—The *Berliner Klinische Wochenschrift*, for June 15, 1874, no. 24, contains the report of a case of adder-bite thus treated. The patient was a boy, aged nine, who had been bitten the day before he was seen by Dr. Kleinschmidt, whilst gathering fruit. The bite was said to be on the middle finger of the right hand. When seen, he had a staring look, his face was covered with cold sweat, and the whole of his right arm was enormously swollen; the skin was very tense and livid, and so tender that he screamed at the least movement. On measurement, the upper arm measured 30 centimètres (12 inches), and the forearm 32 centimètres (12½ inches), whilst the measurements of the left upper arm and forearm were 16 and 15 centimètres (6½ and 6 inches) only. The swelling extended also to the right chest and side, which were covered with a rash resembling scarlatina. The axillary glands were swollen. Although the bite could not be seen, the middle finger and the back of the hand were the seat of bullæ. No excision or cauterisation of the wound was to be thought of under these circumstances. Leeches were therefore ordered, as these had proved of service in another less severe case of adder-bite seen eight days before. Liquor ammoniæ was given in solution, and a purge; also ice, to check vomiting, which was almost continuous. Next day he was worse; had passed a very bad night, had vomited five times, and the arm was still more swollen, so that the upper arm was 32 centimètres, and the lower 34 centimètres (12½ and 13½ inches). There was more swelling of the whole right side, and of the scrotum also. His pulse was small and quick (120), his temperature 39.9° C. (103.8° Fahr.) and there was an expression of extreme anguish on his face. Much troubled by the danger of the case, the doctor ordered fresh leeches, and the ammonia to be taken hourly, but seeing on his return home the report of a case treated by ammonia subcutaneously injected, in no. 28 of the *Berliner Klinische Wochenschrift* for 1873, he seized his Pravaz's syringe, returned to the house, and injected a syringe-full of a solution of 1 of strong liquor ammoniæ to 4 of water, near the axilla. The boy roared for half an hour, but by evening all vomiting had ceased, there was no more swelling, and the anxious look had

vanished. In the evening, as the arm was still painful, some incisions were made with a pointed bistoury; much greenish-yellow serum exuded from these openings. Next day the swelling was much less, the boy looked cheerful, and his appetite returned. In fact all bad symptoms had vanished, though some eight or ten days more were required for recovery. [Dr. Kleinschmidt, commenting very fairly on his own case, remarks that, as only four per cent. of such bites are fatal in Germany, he will not assert that this treatment saved the boy's life; but he cannot doubt that immediate relief was gained from the subcutaneous injection of the ammonia-solution. In this the reporter thinks his readers must agree, although some part of the relief was probably due to the incisions.—*Rep.*]

W. BATHURST WOODMAN, M.D.

FORGET ON RANULA. — *L'Union Médicale* of June 25 and 27, contains a paper by M. Forget upon foreign bodies in Wharton's duct, and their connection with ranula, which was read at the Surgical Society. M. Forget deals critically with two papers bearing on the subject, the one by Dr. Claudot, the other by Dr. Ferrier.

M. Claudot's consists of two parts. In the first he narrates various cases of ranula, and concludes that they differ in their origin, their seat, and their nature. Hence, he classifies them into

1. Mucous cysts (dilatations of the muciparous follicles).
2. Salivary cysts (distensions of the salivary ducts).
3. Serous cysts (Fleischman's bursa).
4. Dermoid cysts (closed cavities of new formation).

M. Forget, passing over the earlier parts of the essay, takes exception to the serous cysts which are said to have their origin in Fleischman's bursa. M. Claudot gives no proof of the anatomical existence of such a bursa. He only says that in 1842 Fleischman believed he had discovered one in the linguo-maxillary furrow, and that he there fixed the seat of ranula. But, unfortunately, the description Fleischman himself gave of it showed that it was nothing but the lax cellular tissue which all anatomists have recognised in that situation. Neither does Jobert (De Lamballe), who follows Fleischman, give any anatomical proof of the existence of the bursa. According to him the direction and shape of the serous cyst itself indicate the situation and direction of the bursa, which has been its original point of departure. The tumour, he says, becomes prominent at the side of the tongue. It is never situated in the central line, because of the resistance of the thick muscular plane there formed by the genio-glossus, the genio-hyoid, and the digastric muscles; it tends, therefore, to place itself at the sides, and to insinuate itself between the muscles and the submaxillary gland; it may develop itself on both sides, and may become prominent at the same time both in the neck and in the mouth.

Now, says M. Forget, it is incontestable that sublingual tumours which offer these clinical features form the great majority of what are commonly called ranulas; must we then conclude with Jobert, not merely that they occupy a closed cavity formed at the expense of the laminated tissue, but even that they arise in a pre-existing natural cavity, which was discovered by Fleischman, and rediscovered by M. Tillaux. It must rest with anatomists to decide who

are right; but at present the balance of authority is against Fleischman. M. Tillaux says the bursa is not always found. Well then, it has probably no very important physiological use; and this leads us to ask whether, when it exists, it is not merely accidental or abnormal? If it had a physiological use it would be constant.

M. Tillaux has striven to show that the accumulation of saliva in this cavity, from a communication with Wharton's duct, gives rise to cases of acute ranula. But the proof is defective, while on the other hand M. Dolbeau has cited cases of acute ranula arising spontaneously, whose sudden appearance could not be explained upon the theory suggested by M. Tillaux; and the author has himself reported a case of the same kind which could not be explained in this manner. There is, therefore, need for further investigation before the point can be considered settled.

The second part of M. Claudot's essay is occupied with lesions of the salivary ducts, produced by foreign bodies in their interior. Of these foreign bodies some are introduced from without; others, such as salivary calculi, have their origin within.

A few examples are given of foreign bodies introduced from without. The first is that of a shoemaker, who had a painful swelling in the region of the submaxillary gland, with ulcerations at the orifice of Wharton's duct. A probe was passed, but no calculus or other foreign body could be felt. Three months later the patient complained of pricking pain under the tongue. The surgeon examined the floor of the mouth, and drew out a pig's bristle, such as the man used in his trade. He speedily recovered.

The next case is that of a soldier, who had a fluctuating tumour the size of a pigeon's egg, beneath and to the outer side of the tongue, in the region of the submaxillary gland.

There was also a second almond-shaped swelling of which the narrow end corresponded to the orifice of Wharton's duct. M. Claudot thought at first that these swellings were probably connected with a concretion in the salivary ducts. However, after making a close examination, he came to the conclusion that there was no foreign body present. After using palliative treatment for a week with little effect, he slit up the orifice, and the bistoury struck a small, rough body, which was drawn out, and proved to be a fragment of an ear of corn, upon which the salts of the saliva had formed a concretion. The cure was rapid and complete.

A third case is that of M. P. who, after having supped upon fish, awoke in the night with sharp pain and swelling in the region of the submaxillary gland. Leeches were applied, and some relief given. Between 1837 and 1842 the patient suffered two sharp attacks similar to the first. All this time the swelling continued; the pain got worse and worse, the tongue deviated, and mastication was impeded till at length M. P. could only take fluid food. It was not till 1842 that the surgeon probed Wharton's duct, and detected a calculus, which he proposed to remove on the morrow. After this probing the patient felt a pricking pain under the tongue, and, placing himself before a looking-glass, he observed a sharp-pointed stone protruding, which by the aid of a large pin he succeeded in extracting for himself. The concretion was cone-shaped, and was formed around a fish-bone.

Though such cases are comparatively rare in the

human subject they are said to be common in horses and other domestic animals. Immediate removal is the essential point in the treatment, otherwise a false passage may be the result. The following case treated by M. Ferrier illustrates this.

A patient, R., had a tumour on the level of the lower jaw, which had been growing for two years. Six months before his admission to the hospital this began to press on the tongue, while it increased also on the outer side; and there was a whitish, fetid discharge on the level of the frænum. A month later a smooth white stone of conical shape came away. The base was rough, as if the calculus had been broken off from a larger concretion, which remained behind. The patient got somewhat better, but as the symptoms returned and it was evident that there was still some concretion in the salivary passages, and that the gland was inflamed, M. Ferrier (wrongly, as M. Forget thinks) made an incision on the outside of the neck, as if he had been going to tie the lingual artery, and dissected out the submaxillary gland. No concretions were found in the gland-tissue, which was only inflamed. A few days later caustic was introduced into the wound, and subsequently caustic arrows were inserted. When the eschar separated, a fistulous track was felt, and the fetid discharge continued. At length, after the patient had suffered much, the fistula was examined with the finger, and a hard substance was felt. The fistula was dilated, and a calculus removed. The fistula then speedily healed, and in two months the patient was well.

M. Forget condemns the treatment adopted in this case, and says that the second portion of the calculus ought to have been removed from the mouth like the first, and that the submaxillary gland should have been left entire.

W. FAIRLIE CLARKE.

TOXICOLOGY.

BERGERON AND L'HÔTE ON A CASE OF LEAD-POISONING.—The authors record a case, occurring in the department of the Seine-et-Marne, of the poisoning of twenty-six persons. These were supposed to be affected with biliary typhoid fever; but two died, and examination proved lead-poisoning. It was found that the drainage-pipes into the reservoir supplying the water the sufferers had drank of, was a tube of lead about one yard in length, which had been laid nearly twenty years. The water from this pipe behaved as a solution of a salt of lead; and the cause of poisoning was doubtless the slow absorption of the lead, as chloride dissolved in chloride of sodium.

PAGET HIGGS, D.Sc.

JACOBS ON POISONING BY COAL-GAS.—Dr. Jacobs, of Cologne, who is a medical officer of health, publishes in the *Berliner Klinische Wochenschrift* for July 6, 1874 (no. 27), three cases of poisoning by coal-gas. He thinks that there are no cases on record (except perhaps casual notices in the newspapers), but those of Tourdes and Schumacher (see Dr. H. Eulenburg, *Die Lehre von den schädlichen und giftigen Gasen*, p. 165-69), and one in the *Annales d'Hygiène et de Médecine légale*. [In this, however, he is mistaken, as Sonnenschein says that the cases known are exceedingly numerous (*Handbuch der gerichtlichen Chemie*, p. 294), and the reporter finds references to other cases in the New Sydenham Society's *Year-Book* for 1859 (pp. 385 and 467), and

reference to a paper by Dr. Aldis (founded on experiments on rats), in the *Med. Chir. Transactions*, vol. xlv. pp. 99 and 137. An abstract of Schumacher's cases will be found in the New Sydenham Society's *Year-Book* for 1862, p. 468. But this does not diminish the interest of these cases, more particularly as those attacked were of different ages.] On February 14, 1870, a married couple named Mathar, with a daughter aged seven, were found in their beds between 6 and 7 A.M. without consciousness or any sign of life, in a cellar at a place called Eupen. The man was forty-seven, the woman forty-six years of age. All three had been healthy. It was found that the man had played cards in this cellar with some friends till after midnight. A lamp was still burning on the table, which (as he afterwards explained), he had forgotten to extinguish; having gone to sleep very soon after going to bed, as did his wife and child. A strong smell of gas was perceptible, indeed his friends had remarked it on going home, and it was found that the main gas-pipe in the street had a large leak, and from this the gas escaped through a drain into the cellar of a house fifty paces off, and from this into the one where these people lived and slept. It must be noticed here that the cold weather from February 6 to 14 was unusually severe, and this had hindered the escape of the gas into the street. The attempts at resuscitation were successful, and received legal recognition. The poisoned persons exhibited the recognised symptoms of asphyxia, and paralysis of the heart. As regards their recovery, it is to be noticed that trismus and tetanus lasted eighteen hours in the girl, twenty-four hours in the man, and thirty-six hours in the woman. Speech and consciousness returned in the girl after twenty-four, in the man after thirty, in the woman after forty-eight hours. They all exhibited a great inclination to sleep for many days, and suffered from constipation and retention of urine, requiring clysters and catheterism. The earthy colour of the skin was remarkably shown by all three, particularly in the woman. She exhibited also, at a later date, peculiar trophic changes in the skin and epidermoid structures, consisting of œdema, yellowish-brown coloration of the skin, thickening, dryness, and desquamation of the epithelium, swelling and stiffness of the right knee-joint, and numerous spots of gangrene. On the left side of her seat there was a bed-sore as large as the palm of the hand, the same on both heels; and the skin over both trochanters sloughed, in spite of all the care of the nurses. The emaciation, lassitude, and weakness, were such that it was four months before the woman could leave her bed for an hour or two, and now, after three years, she has scarcely regained her former strength. The man, too, even now, is a little weak-minded. The relation of pulse to temperature is worthy of note. At first the pulse in both man and woman was lowered, whilst the axillary temperature was raised. The child, however, had her pulse quickened, and her temperature elevated simultaneously. The woman had also horrible pain in her left leg, so that she had no rest either day or night. She described it as an unendurable burning, drawing, pinching, tearing pain, attacking the thigh, knee, and foot, but missing the tibial portion of the leg. Opium, chloral-hydrate, morphia internally and subcutaneously, quinine in large and small doses, and iron, all gave but slight and transitory relief.

Dr. Jacobs appends the following remarks. Coal-gas is thus seen to affect the blood in its passage

through the lungs, so as to render it unfit to carry on vital processes. Death is therefore not a mere act of suffocation, but just as definite a method of poisoning as that by strychnine, nicotine, atropia, or opium. The carbonic oxide of coal-gas (which is the only essential ingredient in fatal cases) possesses an irresistible property of robbing the blood of its atmospheric oxygen, and putting itself in its place. But this affects not only the central organs, but even the skin, as shown by the peculiar coloration, œdema, desquamation, gangrene, etc. Similar alterations of skin are also met with in central nervous diseases, e.g., chronic desquamative myelitis. It might be thought that the smell would irritate the nose and give warning; but this case shows the opposite. All soon fell off to sleep, and lost consciousness. So Dr. Carnet's experiments with animals teach us. He experimented on a rabbit, two pigeons, and a greenfinch, with carbonic oxide. In half an hour the three first were insensible, the greenfinch dead, as well as a rat which had crawled into the chamber. The insensibility was preceded by muscular weakness, and tottering gait. This stage has, therefore been justly called the stage of stupefaction. Giddiness, headache, nausea, and inclination to vomit, or actual vomiting, generally precede stupefaction (compare Schumacher's cases, in Henke's *Zeitschrift*, 1862, p. 40—see reference above) but the present case shows that this is not invariable. Even when roused to the danger, there may be no power to escape. The fact that the gas does not irritate the nose, lungs, etc., arises in a great degree from the fact of its large percentage of carbonic oxide, a gas which irritates none of the sensitive nerves—being invisible, tasteless, odourless, etc. It begins its insidious and fatal operation in the lungs. Trismus and tetanus were present in our cases, as in those reported in the *Oesterr. Zeitschrift für prakt. Heilkunde*, 1862, no. 49. Convulsions may have preceded these (so-called stage of convulsions), but the position in bed, and the absence of contusions seem to negative this. Tourdes' case was fatal without previous convulsions (Tourdes, *Relat. Méd. des Asphyx. occasion. à Strassbourg par le gas de l'éclairage*, 1841, p. 47). It has been propounded that 'the frequency of the pulse is a consequence of the elevation of temperature.' In the three cases related above, the pulse could scarcely be felt. It was so rapid in the child that it could not be counted, whilst the axillary temperature was 39.7°C. (103.46° Fahr.): the pulse and temperature were thus both high. But in the man and woman the pulse was slower than normal, whilst the woman's temperature was 40°C. (104° Fahr.) and the man's 38.5°C. (101.3° Fahr.). We might ascribe a pulse-depressing power, as regards adults, to the gas, as Hagenbach does to the poison of abdominal typhus. But this is seen at the onset of many diseases (pneumonia, cerebral pressure, &c.), whilst in children the pulse is usually quickened at first. Both in the man and woman the pulse was quickened afterwards. It was not true, however, that the pulse-frequency bore any definite relation to the duration of the high temperature. The fact of the lamp continuing to burn, without explosion, is also noteworthy. Death may also occur when the taps are turned so as to extinguish the flame, but not to prevent escape. Two servants of the Prince of Waldeck, at Deutz, were found dead in bed from this cause. The gas was not shut off at the meter, and one of the taps was not properly turned off in the room in which they slept.

[As regards the last case, it seems to the reporter more probable that the gas was *blown out*, after having been turned down low. He thinks that the poisonous action of hydrogen sulphide must not be forgotten, as regards ordinary coal-gas, though the blood-spectra (not mentioned here) would be very different (see Preyer, *Die Blutkrystalle*, Jena, 1871). Dr. Aldis's rats had convulsions; it does not appear that the gas was examined as to its chemical constitution.—*Rep.*]

W. BATHURST WOODMAN, M.D.

NEW INVENTIONS.

ON CERTAIN IMPROVEMENTS IN THE HINGED SHORT FORCEPS.* By FRANCIS VACHER.

In my paper descriptive of, and remarking upon, a new form of midwifery forceps, issued last year, I stated that, though convinced the principle on which my instrument was constructed was sound, I could not pronounce it a perfect short forceps. Indeed, in the course of the first delivery it accomplished,

one defect, viz, the position of the button commanding the steel snap, became apparent, and since then two other flaws in the original design have discovered themselves, one, the instrument's extreme shortness, and the other, its want of some modification which would enable the operator to unlock and withdraw the blades without previously returning them into the hollow of the sacrum. These three imperfections I have, with the kind assistance of Messrs. Weiss and Son, whom I personally consulted on the subject, been enabled to correct. In what manner will be seen at a glance by comparing the accompanying cut with the illustration to my former paper.

In the first place, the catch which locks the blades when *in situ* is controlled from the end of the half of the handle attached to the upper or outer blade instead of from the front of the half the handle belonging to the lower blade, so that with the new instrument there is no possibility of the operator involuntarily unlocking it by the pressure of the palm of his hand during traction.

Secondly, inasmuch as this forceps is intended for

effecting delivery of the head when in the pelvic cavity, no less than when it has in great part passed through the outlet, I have found it necessary to increase its length by removing the clams a little further from the handle by the introduction of strong shanks an inch and a quarter in length.

Thirdly, it having been pointed out to me that, should delivery prove impracticable after traction had been sufficiently long tried, it would be an advantage to be able to separate the blades, and remove them right and left in the ordinary way, I have had the hinge rivet fitted with a head to allow of its being readily drawn.

It will be observed also that the black wood handle previously figured chequered now appears plain, as I intended it should in the first instance, having found by experience how very troublesome it is to keep clean handles of any instruments mounted in chequered wood.

I may only add that the hinged forceps, as now re-submitted to the notice of the profession, while obviously more useful than the pattern at first planned, is so little increased in size and weight that it is still, I believe, the smallest, lightest, and most portable short forceps devised.

REVIEWS.

Hygiene in its Relation to Therapeutics. By ALFRED L. CARROLL, M.D. Pp. 37. New York: Turner and Mignard.

This short paper, read before the New York Medical Journal Association in 1869, is evidently the result of much labour, and deserves to be read with careful attention. The author considers that hygienic measures are not only valuable in preventing disease, but have a much greater share in removing it than is generally assigned to them. The diseases which can be treated by drugs alone form but a very small class, consisting of certain cases of local disease, poisoning, and mechanical obstruction. Those which yield to hygienic measures alone form a much larger class than is commonly supposed, including self-limiting diseases, functional derangements, and deviations from the normal standard of nutrition. The largest class of all, however, including many chronic diseases of the circulatory, respiratory, and nervous systems, yields only to a combination of drugs and hygienic agents. These agents are alimentation, air, temperature, exercise, bathing, electrical influence, sunlight, etc. Alimentation in disease is most important, for in all organic diseases an essential part is played by tissue-starvation. The muscles may be starved by want of nitrogen, the fats by deficiency of carbon, the brain by absence of phosphorus, and the blood by withholding salts of lime, potash, soda, iron, and magnesia; although the other tissues may be amply supplied with the nutriment requisite for them, one may be suffering from want. In trying to supply nourishment, the first object to be kept in view is the general nutrition of all the tissues, and the second is the especial nutrition of the starved or over-gorged ones. It is not sufficient, however, merely to give nutriment; regard must also be had to the power of assimilation, for, if this be deficient, the patient may starve on four hearty meals a day. The comparative powers of gastric and intestinal digestion must, therefore, be taken into consideration, for sometimes the stomach

* An Appendix to 'Remarks on a New Midwifery Forceps,' *Liverpool and Manchester Medical and Surgical Reports*, 1873.

may be able to digest when the intestines cannot, and *vice versa*. 'Thus, for instance, we may have a case wherein respiratory food is called for, and yet the alkaline intestinal digestive function may be inadequate, while the stomach is still in working order. Here, and in all cases where emaciation and innutrition are caused by excessive oxidation of albuminous matter, the ingestion of gelatin will be found useful, since it offers us respiratory materials digestible in the stomach.' (For some interesting experiments by Voit on the use of gelatin as food, *vide* LONDON MEDICAL RECORD, vol. i. p. 367). 'In the special nutrition of tissues, the deficient elements should be ascertained, and then administered; or substances containing them in large proportion should be selected as food. Thus, where nervous power is deficient, hypophosphites may be given, and meats which are rich in phosphates, or still better, fish, should enter largely into the regimen. Meats and milk contain iron, and thus should form a chief portion of the diet in anæmic conditions. Useful indications of the proper articles of food are often afforded by the desires of the patient. As the needs of the solids or fluids are generally expressed by the sensations of hunger or thirst, so specific wants of certain tissues are frequently shown by a craving for a certain kind of food. In winter we have an instinctive liking for fatty substances which are repugnant to us in summer, as, per contra, we fancy in hot weather acidulated drinks and non-respiratory substances from which we are inclined to abstain in the winter months. In disease, within certain limits, a strong desire for a particular article of diet may be regarded as the still small voice of some suffering tissue urging its wants above those of its fellows, though of course due allowance must be made for the perversions of appetite which occur in many forms of disease.' Sometimes the opposite treatment of withholding certain elements may be useful as, *e.g.*, in the rheumatic diathesis, where lactic acid is in excess, and vegetables containing starch and sugar should be to a great extent avoided. Where there is a tendency to excessive secretion of mucus, substances liable to undergo lactic fermentation should be to a great extent withdrawn. The other hygienic agents are treated more briefly than alimentation. The author recommends an open fire-place and an inlet for pure air at the upper part of the room as the best practicable means of ventilation, and fully opened doors and windows when the season permits. He considers that constant humidity, by diminishing the exhalation from the body, and probably also through absorption from without, increases nutrition, while it lessens innervation. He draws attention to the fact that *cold dry* air, through its non-conducting property, acts in some sort as a conservator of animal heat, while *hot dry* air on the other hand is to a certain extent a cooling agent, owing to the rapidity with which evaporation of the perspiration occurs. When the air is moist it has an opposite action; for *cold moist* air, being a good conductor, is a speedy refrigerant, while *hot moist* air, by preventing evaporation, augments the bodily heat. This is important in regard to the distinction between vapour and hot-air baths, which are sometimes prescribed indifferently by the practitioner, but the latter of which can be borne much longer than the former. Very dry air dries and cools the lungs rapidly, and therefore, when stoves are employed to warm rooms, some water ought to be evaporated. In regard to climate, the author recommends that 'a

tendency to visceral engorgements, or to hæmorrhagic troubles, should be met by a warm, humid, and not too elevated a locality; scrofulous, dropsical, or diarrhœal disorders, and generally those accompanied by excessive mucous secretion, call for warmth and dryness; many nervous maladies will be benefited by a temperate climate, combined with moisture. The well-known effects of dry hot climates in causing derangement of the liver and bowels sufficiently indicate the opposite conditions to be sought for their relief. The influence of climate with regard to temperature alone may be generally stated thus. Heat tends to increase the activity of nutrition; but at the same time the amount of caloric which must be carried off by transpiration induces, by calling an excess of blood to the surface, a sluggishness of the digestive functions and rapid exhaustion. Owing to the abundance of perspiration, all the secretions are diminished with the exception of bile and semen, and these are on the contrary increased in hot climates. The fact that the skin may be made to act vicariously for the kidneys points to the value of hot dry climates, either natural or artificial (as the hot-air bath) in some renal disorders, if not otherwise contra-indicated. Cold, on the other hand, diminishes the cutaneous action, drives the blood from the surface to internal organs, renders the circulation sluggish, and increases the secretions generally.' Where excessive oxidation is going on, and the nutritive resources must be husbanded, rest is indicated. Under other circumstances, exercise in moderation is even more important in disease than in health; but violent gymnastic exercises are frequently injurious, and cardiac disturbance is very prevalent among acrobats. Bathing and electricity are briefly touched upon, and the free admission of sunlight to the rooms of the sick and convalescent is strongly recommended in nearly all cases, except those of ophthalmic disease, or where acute cerebral or meningeal attacks forbid it. Unless too intense, or too long continued, it acts, according to Dr. Hammond, as a most healthful stimulant, both to the nervous and the physical systems. The delirium and weakness which are not seldom met with in convalescents kept in darkness disappear like magic when the rays of the sun are allowed to enter the chamber, and wounds sometimes appear to heal with greater rapidity when the light is allowed to reach them, than when they are kept constantly covered.

T. LAUDER BRUNTON, M.D.

The Essentials of Materia Medica and Therapeutics.

By ALFRED BARING GARROD, M.D., F.R.S., etc. Fourth edition. Revised and edited under the supervision of the Author, by E. BUCHANAN BAXTER, M.D., etc. London: Longmans & Co. 1874.

The rapidity with which former editions of this work have been sold clearly indicates the high esteem in which it is held by the medical public, and affords the best possible proof that it has well supplied a widely felt want. The absence of all information regarding the physiological action of medicines in previous editions, however, has been a serious defect in the book, and has detracted considerably from its value. This fault has now been remedied, and the present edition contains an account of the physiological action of the most important remedies. The preface leads us to believe that this part has been added by Dr. Buchanan Baxter, who has lately been appointed successor to Dr. Garrod in the chair of Materia Medica in King's College. The chief

drugs of whose action an account is given are phosphorus, iodine, hydrocyanic acid, arsenic, iron, mercury, alcohol, ether, nitrite of amyl, chloral, croton-chloral, nitrous oxide, carbolic acid, aconitia, the alkaloids of opium, Calabar bean, eucalyptol, conia, quinia, strychnia, gelseminum, condurango, atropia, digitalis, camphor, veratria, veratroidia, and viridia. The descriptions of their action are very brief, but they are at the same time very clear and accurate. One is tempted occasionally to wish for a little more detail, but this could hardly have been given without materially increasing the size of the book, and the brevity and conciseness are in thorough keeping with its general character. The author has evidently taken great pains not only to acquaint himself with recent researches on the action of the remedies he describes, but also to select the most probable accounts where authorities are doubtful or contradictory, and he has succeeded in increasing the utility and value of his work, great though these already were.

T. LAUDER BRUNTON, M.D.

On the Past, Present, and Future of Therapeutics.

By ROBERT FARQUHARSON, M.D., M.R.C.P.
London : Smith, Elder, and Co., 1874.

This introductory lecture, delivered at the opening of the course of materia medica in St. Mary's Hospital, contains a brief sketch of the development of therapeutics, and gives a most hopeful view of its future progress. Some remarks on the present method of teaching materia medica are very good, and must have been received by the students with rapturous applause. The lecturer sympathises with the hardship they endure in being obliged during their materia medica course to listen to and learn a great many things, which they will afterwards promptly throw overboard as being entirely useless. To lessen their labours, he proposes the adoption of Harvey and Davidson's suggestion that students should not be made to 'get up' all the details concerning 900 drugs, many of which are hardly ever used, but that their attention should rather be concentrated in mastering thoroughly a selected number of the most important ones. Dr. Farquharson also makes some sensible observations on the period of their curriculum at which students in London attend materia medica; and his views on this subject are well worthy of attention. T. L. BRUNTON, M.D.

MISCELLANY.

THE Francis-Joseph University, newly instituted at Agram, in Croatia, will be opened in October.

DR. NOTHNAGEL, professor in the medical faculty of the University of Freiburg, has accepted an invitation to the office of director of the hospital at Jena.

THE DEER DISEASE IN PRUSSIA.—The *Standard* of July 25 reports the outbreak of a murrain amongst the deer in the royal forest of Grunewald, which has swept away almost entire herds. From the name, milzbrand (spleen-gangrene), and the description given of the symptoms, which include suppurating carbuncles, fungous growths in the blood, etc., and the fact of its contagion being carried by flies, it appears to be identical with charbon, or malignant pustule. Professors Virchow and Liebreich have investigated the cases. The former says that simple burial is not enough to destroy infection, since the maggots hatched from the buried eggs will come to light, become flies, and spread the infection anew.

TRICHINOSIS.—This disease is reported to have attacked many persons in Nordhausen and the neighbouring villages, in consequence of their eating raw pork. In Nordhausen alone, forty-three persons were attacked.

PROFESSOR VON PITHA, of Vienna, has retired from his official duties after nearly fifty years of public service. The Emperor has conferred on him the Order of the Iron Crown of the second class.

NEW ACT ON APOTHECARIES.—This Act has lately been printed, having received the royal assent. The first section enacts that the Act shall be cited as the Apothecaries' Act Amendment Act (1874). The second section repeals those provisions of the Apothecaries' Act of 1815 which require any member of the Court of Examiners (or any of the five apothecaries to be appointed under the Act for examining-assistants to apothecaries) to be a member of the society of not less than ten years' standing. The same section repeals those provisions of the Act of 1815 which require candidates for examination for a certificate to practise as an apothecary to have served an apprenticeship of five years. The third section enables the society, with the sanction of the Privy Council, to form part of any conjoint examining board to be constituted under the provisions of the Medical Act of 1858. The fourth section provides for the society having power in certain cases to strike licentiates off their list. The fifth section saves any existing rights of women to be admitted to the examinations of the society. Independently of the power given to the society to form part of any conjoint examining board, the Act will therefore be found to effect the following important changes:—1. The society can for the future select their examiners from the whole medical profession, or from any scientific body instead (as formerly), from a very limited class of the members of the society. 2. Apprenticeship is no longer made a necessary condition required of candidates presenting themselves for examination for a certificate to practise as an apothecary. 3. The society can strike licentiates off their list on the same grounds as they can be struck off from the *Medical Register*. It may be observed, in conclusion, that no new rights are conferred upon women by the fifth section of the Act.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, AUGUST 12, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

THE INTERNATIONAL SANITARY CONFERENCE IN VIENNA.*

(Continued from page 479.)

II. Quarantine against Cholera.

The following were the questions prepared regarding this subject.

12. Ought land-quarantine establishments to be instituted against cholera?

13. If so; (a) where? (b) at what time, and in what circumstances? (c) with what building and administrative arrangements? (d) by what means is cholera to be prevented from entering the country by other ways than through the quarantine establishments?

14. Should river-quarantine establishments be instituted against cholera?

15. If so; (the same questions as in no. 13).

16. Should sea-quarantine establishments be instituted or maintained against cholera?

17. If so; (as in no. 13).

18. What dispositions in regard to persons should be made with free intercourse and continuancy?

19. How long (in case observation or quarantine should have been determined on) ought healthy persons to be subjected to observation or special quarantine? and how long ought the sick to be detained in hospital?

20. Under what conditions, and according to what calculations, is the entrance of ships into quarantine to be reckoned?

21. What regulations with respect to (a) personal effects, (b) living animals, (c) merchandise (d) food, (e) means of conveyance (e.g., ships, wagons, &c.) ought to be permitted with regard to permissions of intercourse without previous disinfection or after disinfection has taken place?

22. What would be the means of disinfection in regard to (a) persons, (b) personal effects, (c) living animals, (d) merchandise, (e) means of transport?

The first of these questions (12) was very thoroughly discussed. The delegates from the oriental maritime countries, who had at command an abundant amount of experience, argued that land-quarantine is only fitted for thinly populated countries, and that perhaps it is only in the east that it can be carried out. The majority of the German, English, Italian, Norwegian, and Roumanian delegates, speaking with reference to the conditions of intercourse in Europe, expressed a decided opinion against the establishment of land-quarantines; while a minority would have it left to individual governments to institute land-quarantines in

their several countries according to their own judgment. The Conference finally arrived at the following conclusion. 'Considering that, since intercourse in the present day has made various advances and is steadily making progress, land-quarantine is impracticable, useless, and injurious to the interests of commerce and intercourse; the question whether land-quarantine institutions ought to be established, is answered in the negative.' With the negation of the principal question, the secondary questions (13) fell to the ground.

On the subject of sea-quarantine, a report was presented by a committee that had been appointed to examine the subject, consisting of Professor Hirsch, Dr. von Alber-Glanstätten, Dr. H. von Kapelle, Professor Semmola, and Dr. Seaton. The report was as follows.

Sea-quarantine can afford an effectual preservation against cholera in those seaports only which may be regarded as the special gates of exit for cholera in its spread towards Europe by the way of sea. These quarantines must be international institutions. When cholera has once passed beyond these points, quarantines are without value in the ports of the European continent, as travelling on land remains free, and deprives them of their value. Under these circumstances, in place of quarantine in European ports, there should be instituted a strict system of examination of every ship arriving from an infected locality. The regulations which the committee have drawn up with regard to the carrying out of this system of examination, with a view to existing maritime intercourse for the purpose of preventing the spread of cholera, recommend the establishment of a sanitary board, partly composed of medical men and partly of administrative officials, in every seaport open to intercourse, whenever cholera is threatened or has been introduced. This board shall receive official information as to ships coming from infected ports, as well as all ships which during the voyage have touched at infected ports, or communicated with infected ships, or on board of which cases of illness or death suspected to be from cholera have occurred (regarding which the captain and officers must be bound under penalty to give true information), and it shall then subject the crew and passengers to a careful medical examination with regard to the state of their health; such examination to comprise not only the individuals, but also their effects, the ship's cargo, and the ship itself. If no cases of illness have occurred on board, the ship is to be at once admitted to free *pratique*; if the contrary be the case, the bodies of those who have died from cholera are immediately to be taken on shore and buried, the patients taken to a hospital, and the remainder of the crew and passengers, under the supervision of the board, subjected to cleaning by means of baths containing freshly dissolved lime. At the same time, all the clothes which healthy persons have used during the voyage, and their other effects, are to be subjected to the disinfecting action of sulphurous acid; and the ship also, after the removal of all on board, shall be subjected in all its compartments to a similar disinfection. The goods disembarked from the ship are to be admitted at once to free *pratique*. If there be no accommodation for the sick on land, the ship, with the patients, the cargo, and the necessary complement of crew, must remain in an appointed place under observation, until the cases of cholera have ended either in recovery or

* From the *Allgemeine Wiener Medizinische Zeitung* and the *Allgemeine Medicinische Central-Zeitung*.

in death. The regulation includes also some special directions for the baths and means of disinfection.

In the general debate on the proposals of the committee, two opposite opinions were held; one being in favour of the continuance of the present sea-quarantine; the other in favour of its removal and of the introduction of a strict system of revision as proposed by the committee. The Portuguese delegate, Dr. de Souza-Martins, insisted on the great value of sea-quarantine in epidemics of cholera, and endeavoured to weaken the arguments which the committee had adduced in favour of its removal.—Dr. Orphanides also spoke in favour of sea-quarantine, and supported his opinions by his observations in Greece.—Dr. Miloslavich supported the quarantine system from a scientific point of view.—The Turkish, Egyptian, and French representatives also spoke in favour of sea-quarantine.—On the other side, the opponents of the system, Dr. Dickson, Dr. Kjerulf, Dr. Berlin, Dr. Schleisner, Dr. Semmola, and Dr. van Kapelle, adduced evidence from their respective countries to show the uselessness of sea-quarantine and the special advantage of a system of observation.—Dr. Hirsch, Dr. von Pettenkofer, Dr. Drasche, and Dr. von Sigmund showed, from the abundant experience at their disposal, that, however rigorously sea-quarantine might be carried out, it was not capable of warding off cholera.—The representatives of Switzerland and Luxemburg spoke in favour of the maintenance of quarantine.—Drs. Semmola, Kjerulf, and Polak expressed a strong opinion, which they supported by numerous facts, that sea-quarantine was injudicious.—Dr. Fauvel replied to them in a long speech, in which he specially referred to climatic differences and the local conditions consequent thereon. He proposed a motion, which was not agreed to, to refer the question again to the committee, and to add to it two of the opponents of quarantine.—The conference, however, adopted a proposal made by Dr. Semmola, to refer the subject to the committee for the special consideration of the opinions advanced by the opposition.

The following propositions, with regard to sea-quarantine, were finally adopted.

‘1. In seaports in which there are no quarantine institutions, as in those of the Red and Caspian Seas, a sanitary board shall be constituted, consisting of medical men and government officials, with a staff of assistants.—The number of members of the board belonging to each class is to be regulated according to the amount of shipping intercourse in each port; but, under all circumstances, it must be sufficient to ensure a speedy dealing with the ship and crew, as well as with the passengers. The chief of the sanitary board must keep himself in official communication with cholera-infected ports, which may come into contact, through intercourse by ships, with that to which he belongs.

‘2. Every ship arriving from an unsuspected port, which the captain shall have declared on oath neither to have touched at an infected port nor to have had direct communication with an infected vessel, and on board which no suspected or distinct cases of, or deaths from, cholera shall have occurred during the voyage, is to have free *pratique*.

‘3. All ships coming from infected or suspected ports, as well as ships which come from uninfected ports, but which during the voyage have touched at an infected place, or held communication with an infected ship, or on which, during the voyage, cases of illness or death suspected to be from cholera have

occurred, shall, on arrival, be subjected as soon as possible to a strict medical examination as to the state of health of their crew and passengers. The captain, ship's officers, and medical officer (when there is one) shall be bound to report to the examining physician any suspicious symptoms of illness on board which may have come to their knowledge. If the medical investigation show that no case of illness in any way suspicious exists among the crew and passengers, the ship, with all that it carries, is to be immediately admitted to free *pratique*.

‘4. The bodies of those who have died of cholera, as well as all cholera-patients found in a ship newly arrived, are to be taken on shore; the former must be immediately buried, the latter placed in a hospital always kept in readiness for their reception, or, when there is not one, in some house or barrack or isolated place, or in as isolated place as possible in the country. If any suspected cases of cholera or deaths have occurred during the voyage, or if suspected or decided cases of cholera, or bodies whose death is traceable with probability or certainty to cholera, be found on board a ship on its arrival in port, the crew and passengers, after the removal of the sick and dead, shall undergo a process of cleansing and disinfection under the supervision of the board.

‘5. At the same time, all the clothes worn by healthy individuals, or used by them during the voyage, as well as all their other effects, are to undergo a thorough disinfection in a room arranged for the purpose, under the strict control of the board. After disinfection has been carried out, the effects will be given back to their possessors, who in the meantime will have taken a cleansing bath, and they will then be perfectly free.

‘6. After the removal of all persons, except those absolutely necessary for the service of the ship, any vessel arriving under the conditions named in section 3 is to be subjected in all its compartments to a thorough disinfection.

‘7. The goods landed from the disinfected ship, even the rags and objects used by the cholera patients, after being properly disinfected, are to be considered innocuous.’

Dr. Fauvel brought under notice the evil consequences of overcrowding in emigrant and pilgrim ships, and urged the necessity of a remedy.—Dr. Seaton openly blamed the unhealthy arrangements adopted, especially by some English shipowners.—The Dutch representatives also spoke against the evil.—Dr. Bartoletti regarded the subject as so important, that he proposed that the decision on it should be deferred until the regulations on establishments for sea-quarantine were drawn up. This was agreed to.

A committee was appointed to discuss regulations for quarantine establishments in those countries which might erect them. The Dutch and Italian representatives declined to act on the committee, as it was not consistent with their views on the utility of sea-quarantine. The committee was finally appointed as follows:—Professor Hirsch (Germany), Dr. von Alber-Glanstätten (Austria), Dr. Seaton (England), Dr. Fauvel (France), and Dr. Bartoletti (Turkey). The following rules were drawn up by the committee and accepted by the Conference.

‘1. Vessels from infected ports must undergo observation, which, according to circumstances, may last from one to seven days. In the eastern ports of Europe and elsewhere, though only in certain excep-

tional cases, the surveillance may be prolonged to ten days.

'2. When the Board of Health have sufficient proof that during the voyage no case of cholera, or of any other suspected disease, has occurred on board, the observation is to last three to seven days, reckoned from the medical inspection. If, under these circumstances, the voyage have lasted at least seven days, the surveillance is to be limited to twenty-four hours, to give time for the examination and disinfection considered as necessary. In cases under this category the observation may be held on board as long as no case of cholera or suspicious circumstance occurs, and when the hygienic conditions of the ship allow it. In these cases, the unloading of the ship for disinfection is not necessary.

'3. When, during the passage or after the ship's arrival, cases of cholera or of other suspected disease occur, the surveillance for those who are not ill is to last seven full days, beginning from their isolation in a hospital or whatever place is assigned to them. The sick will be disembarked and properly attended to in a place separated from the persons under surveillance. The ship and all objects belonging to it are to undergo a thorough disinfection, after which persons obliged to remain on board will be subjected to surveillance for seven days.

'4. Vessels from suspected ports, that is, such as lie near places or ports where cholera prevails, and are in intercourse with them, may be subjected to observation lasting at most five days, provided that no suspicious case of disease have occurred on board.

'5. The quarantine of emigrant and pilgrim ships, and in general all vessels whose condition is deemed especially dangerous to the public health, shall be carried out under particular regulations, which the Board of Health will decide.

'6. When the conditions of a place do not allow the prescribed regulations to be carried out, the infected ship is to be despatched to the nearest hospital, after it has received all the assistance that its condition may require.

'7. Ships coming from infected ports which have touched at a port *en route*, and have left it without undergoing quarantine, will be treated as ships coming from an infected harbour.

'8. In cases of mere suspicion, the Sanitary Board may order special disinfection regulations.

'9. In ports where cholera is epidemic full quarantine is not to be kept, but means of disinfection are to be strictly applied.'

(To be continued.)

ON THE FORMATION OF INFLAMMABLE GASES IN THE STOMACH. BY DR. FRIEDRICH SCHULTZE, ASSISTANT-PHYSICIAN TO THE MEDICAL CLINIC IN HEIDELBERG.*

In the 38th, 39th, and 40th numbers of the *Berliner Klinische Wochenschrift*, for 1870, Dr. Popoff published a contribution from the practice of Dr. Botkin, of St. Petersburg, under the title of 'A Case of Contraction of the Pylorus, with Consecutive Dilatation of the Stomach, and Discharge of Inflammable Gases.' In that communication, he mentions an analysis made by Carius of the gases which the patient had discharged from the mouth by eructation;

and expresses his regret that he had not seen the copy of the 'Transactions of the Heidelberg Society of Natural History and Medicine,' in which the report on the analysis was given, and that therefore he could not arrive at a conclusion as to the nature of the disease of the stomach.

More recently, as appears from a brief notice of a meeting of the Society of the Medical Officers of the Charité Hospital in Berlin (*Berliner Klinische Wochenschrift*, no. 8, 1874), Frerichs has described a similar case as occurring in his hospital practice. It therefore seems right to give greater publicity to the history of the case, to which the analysis made by Carius had reference.

In the volume for 1865 of the *Heidelberg Year-Book of Literature*, part 2, p. 726, is the simple statement that Professor Friedrich made a communication regarding a patient who discharged inflammable gases; and following this is a communication from Professor Carius on butyric acid fermentation in the stomach of a patient. Professor Friedrich has never published his communication; the analyses made by Carius are alone given in the *Year-Book*; and I quote his own words, in order to give them greater publicity.

'The examination,' Professor Carius writes, 'which I made by desire of Professor Friedrich of the case communicated by him, was commenced with the analysis of the inflammable gases discharged through the mouth of the patient. They were collected there a few hours after the mid-day meal, at which time, according to the patient's statement, the development of the gases was most abundant. The patient held in his mouth a glass tube, which was connected by caoutchouc with a tube opening under water. The latter was previously filled with water, and closed by a stop-cock. When the patient perceived the presence of the gases, his nose was held and the stop-cock was opened, when the gases escaped quietly in such abundance that at one time 200, and a few minutes later 300, cubic centimetres were discharged.'

'The analysis was conducted according to Bunsen's method, and gave the following result.

| | Per cent. | Volume. |
|---------------------|-------------|---------|
| Carbonic acid . . . | 26'56 . . . | 28'45 |
| Hydrogen . . . | 32'30 . . . | 31'55 |
| Marsh-gas . . . | 0'34 . . . | 0'24 |
| Oxygen . . . | 7'36 . . . | 6'82 |
| Nitrogen . . . | 33'44 . . . | 32'94 |
| | 100'00 | 100'00 |

'Sulphuretted and phosphoretted hydrogen could not be found.

'Nitrogen and oxygen were present in the mixture of gases in nearly the same proportions as in atmospheric air. It might therefore be concluded that these had only been swallowed by the patient, or that they represented the atmospheric air in his mouth, especially as the slight loss of oxygen may be explained by its being more readily absorbed by water. The presence of marsh-gas is easily explained by the origin of the gaseous mixture: its presence in so small a quantity is of no importance. The important constituents of the gaseous mixture were then carbonic acid and hydrogen. I was struck with finding these in nearly equal volumes; and when it is remembered that carbonic acid is much more readily absorbed by water than hydrogen, the comparatively smaller quantity of the former is explained. In the formation of butyric acid by fermentation, carbonic acid and hydrogen are developed in equal volumes; and hence it appears probable that a

* *Berliner Klinische Wochenschrift*, July 6 and 13, 1874.

true butyric acid fermentation took place in the patient's stomach. In order to obtain further proof of this, I subjected to distillation the fluid portion of the matter recently vomited by the patient, which had an intensely sour reaction. In the distillate, which was very acid, butyric acid was found in abundance; from a portion of vomited matter discharged at one time, nearly five grammes of butyric acid were obtained. Along with the butyric acid, the distillate contained traces of its homologues, capronic acid, etc., but no acetic acid. The identity of the acid with butyric acid was determined by analysis, and by the behaviour of its barium salts. From what has been above communicated, there can be no doubt that butyric acid was really formed by fermentation in the patient's stomach. This seems also to have occurred in a second patient, observed by Professor Friedrich; at least, I found almost as considerable quantities of butyric acid in the matter vomited by this patient, who also discharged a large amount of gas.

'Butyric acid is formed by fermentation from sugar, starch, and similar materials; lactic acid is probably first formed, and in the presence of the protein substances undergoes decomposition. It is probable that lactic acid is decomposed in the same way in the stomach of a patient. The only difference that can be imagined to exist is that, in the artificial formation of butyric acid, it is not free lactic acid but a lactate that undergoes change, while there can be no question that it was free lactic acid that was decomposed in the patient's stomach.'

Carius then examined only those gases which were spontaneously discharged from the distended stomach, not the gases remaining in the stomach, which Popoff drew off by a stomach-pump, and then analysed. Both observers have attached too low a value to the carbonic acid, as they collected the gases under water and not under mercury; there is only this difference between them, that, while Carius found nearly equal volumes per cent. of carbonic acid and hydrogen, Popoff found a great preponderance of hydrogen. The last-named observer, however, in collecting the gases contained in the stomach over quicksilver, found the percentage of the two gases nearly the same.

They agree also in assuming the formation of butyric acid in the stomach, in finding that oxygen and nitrogen were present in nearly the same proportion as in atmospheric air, and in not finding any sulphuretted hydrogen; Carius, however, found small quantities of marsh-gas, while Popoff could discover no compound of carbon and hydrogen.

Before I proceed to describe the case of the patient who supplied the gases for the analysis made by Carius, I must mention, that in 1864, in the *Allgemeine Medizinische Centralzeitung*, Waldenburg described 'a peculiar kind of dyspepsia characterised by an abnormal development of gases, and rapidly cured by charcoal after a duration of three years.' These abnormal gases had the smell of addled eggs, were, according to the patient's statement, readily inflammable, and exploded with a visible bluish flame. The patient was much emaciated; his abdomen was excessively distended, the greatest protuberance being below the umbilical region; on percussion, the whole abdomen gave a loud and deeply resonant sound; no other abnormality could be detected. Three years previously, before the patient consulted Dr. Waldenburg, he had suffered much from flatulence, and afterwards, every day about three hours after each

meal, distension of both the upper and the lower parts of the abdomen set in, and subsided at first after the discharge of gases, and afterwards after vomiting. The vomited matter was very abundant, and contained, in a semi-digested state, almost the whole of the meat and drink previously taken, and also cryptogamic spores 'like torulæ.' Sarcinae were searched for once, but were not found.

Waldenburg thought that there was no deeply seated disease in this case, as the patient felt relatively well when his stomach was empty. His appetite was good, and nothing abnormal could be found beyond the distension of the abdomen. It may hence be well assumed that in this case, as well as in the following ones, distension of the stomach lay at the foundation, very probably with narrowing of the pylorus; and this view is supported by the large amount of the vomited matter and by the time at which the vomiting usually took place.

I come now to the cases observed by Friedrich, of which I will relate in detail only the first, as the analyses made by Carius have relation to it.

The patient was a mason, aged twenty-five, who, for a year before his admission to the Heidelberg Hospital, after having on several occasions suffered gastric distress, and having frequently vomited matter like coffee-grounds, was attacked with vomiting every fourth or fifth week. On one occasion, for two days in succession, he discharged by vomiting thirty cherry-stones, although he did not remember having eaten any cherries within seven weeks previously. Latterly, before his admission on January 27, 1865, the vomiting had occurred more frequently, often daily; but sometimes it would cease for some weeks. Before each act of vomiting he felt much distension of the abdomen; afterwards, there was a feeling of great relief. The appetite was good, he had no headache, his bowels had been constipated for two years, at last acting only at intervals varying from three to six days. In the last weeks he had become emaciated, and very weak.

On admission, he was somewhat emaciated; his extremities were cold; there was tenderness on pressure over the epigastrium; no solid tumour could be detected in the abdomen; the tympanic percussion-sound over the stomach appeared more extended than usual. When the patient lay on his back, there was observed a bulging, lying obliquely across the middle third of the abdomen, and extending into both hypochondriac regions; it yielded a clear tympanic percussion-sound, and was caused by the distended stomach. From time to time, spasmodic contractions of the stomach occurred, during which the outlines of the greater curvature were distinctly visible through the abdominal walls. On the sudden application and removal of pressure with the hands at the sides of the upper abdominal region, a squashing sound was distinctly heard, evidently dependent on the presence of fluid and gaseous matters in the distended stomach. The patient could also produce the same sound by shaking his abdomen.

The vomited matter was voided in large quantities; it was very sour, had an odour of yeast, and was of a greyish white colour; on standing, it separated into three layers. The lowest layer was of a whitish grey colour, and on microscopic examination was found to consist of sarcina-balls (large-celled and small-celled) and of torulæ, mostly arranged in the form of rosaries. The upper layer was derived from those parts of the food which were of low

specific gravity, and consisted chiefly of fat, starch, &c. The middle layer, which was the thickest, consisted of an opaque fluid containing very few solid elements, and having an intensely acid reaction. The urine was rendered very cloudy by heat, but again became quite clear on the addition of acetic acid. In other respects, the examination of the patient did not show any anomaly of the inner organs.

During his six months' stay in the hospital, from May 1865, it was ascertained that the gas discharged by eructation—which occurred especially just before the act of vomiting—was inflammable. If at this time a burning match were held before his mouth, the gas took fire with a slight crack, as when ordinary gas is lighted; and a bluish flame more than a foot long was seen proceeding from the mouth of the patient—a phenomenon which could be especially well seen in a dark room. On the other hand, the sour-tasting scanty eructation which generally followed the act of vomiting, did not, as a rule, consist of inflammable gases; it did so, however, on some occasions, and later on it was found that the gases discharged between two acts of vomiting on any one day were combustible. Even the bubbles of froth, which was formed in abundance on the surface of the vomited matter, were filled with combustible gases. On moving a burning match close over the bubbles, there was heard a rapid succession of slight detonations, like miniature fire-firing.

The vomiting occurred almost every day while the patient was under treatment, being especially frequent in the evening and at night. The quantity was often very large, amounting to as much as 4,300 cubic centimètres (more than nine pints).

All the remedies that were used, as well as the most careful regulation of the diet, were without result. Charcoal, which Waldenburg had given to his patient with benefit, had no effect that could be observed; and just as little good was obtained from carbolic acid (two teaspoonfuls in water three times daily of a solution of 1·2 parts of carbolic acid in 30 of distilled water), dilute sulphuric acid, or glycerine (in doses of four teaspoonfuls three times a day). During the use of the glycerine, however, the inflammable gases disappeared, and the amount of sarcinæ was much reduced, although there was still a considerable quantity of torulæ.

In spite of all the remedies that were employed (the application of the stomach-pump in dilatation was not then known) the patient became daily weaker and more miserable; the pain in the epigastrium increased, general wasting made steady progress, petechiæ appeared on the skin of the abdomen, and he died on September 14, 1865. A short time before his death he vomited dark brown tarry matter, and for a few days there was slight jaundice.

The principal fact ascertained on *post mortem* examination, which was made by Professor Friedrich, was extreme dilatation of the stomach. The organ occupied the position in which it had been observed during life; the mucous membrane was somewhat puffy, and was covered with a tough firm mucus. The pylorus felt, when examined from without, like a knobby tumour, about double the size of a nut. (During life, when emaciation was far advanced, a small nodulated tumour was felt in the neighbourhood of the pylorus.) The walls of the pylorus were thickened and hardened, and its lumen was reduced to the diameter of a quill; on cutting it through, the thickened walls presented all

the characteristics of the so-called benign hypertrophy, with predominant hyperplasia of the muscular structure. The stomach contained 5½ pints of a dark coloured fluid having an unpleasant sour smell, and on the surface of its mucous membrane in the neighbourhood of the pylorus were seen radiating cicatrices with elevations between them; recent lesions could not be detected. The only other appearances worthy of note were, a greatly atrophied liver, and numerous abscesses in the right lung, probably produced by the inspiration of particles of food.

It was thus evident that the patient had suffered at an earlier period from ulcer in the neighbourhood of the pylorus, and that the contraction of the cicatrix had given rise to stricture of the pylorus and all its consequences.

Friedrich's second case, which is mentioned by Professor Carius, was one of less marked gastric disorder in a chlorotic girl aged twenty, who from her seventeenth year had frequent attacks of heart-burn, and vomited after food daily, often for months together. Hæmatemesis was never observed; but the patient was troubled with frequent eructation having a nasty taste.

Objective examination showed, besides the signs of well-marked chlorosis, a greatly distended abdomen; there was much tenderness on pressure in the epigastric region, where also, on shaking the abdomen, a squashing sound could be distinctly heard. The vomited matter, often copious in quantity, had a smell of yeast, and separated, as in the other case, into three layers, the lowest of which contained abundant sarcinæ and torulæ. Eructation seldom occurred during the patient's stay of two months in hospital; it could not be ascertained whether the gases discharged were inflammable. Carius found, however, abundant quantities of butyric acid in the vomited matters.

It may be well assumed that in this case also the long-continuing gastric disorder had its origin in an ulcer of the stomach; there was evidently dilatation although only moderate.

A number of similar cases have come under clinical observation since 1864; in two, only, however, was the inflammability of the gases discharged by eructation ascertained, while the bubbles of froth on the surface of the vomited matters were frequently found to be capable of explosion on the application of heat. In all cases there was dilatation of the stomach, in which there was a history of round ulcer and consecutive cicatricial stricture of the pylorus. The patients generally felt relieved, after vomiting, of the feeling of gastric distension; and objective examination also then showed that there was a decrease of the epigastric enlargement, and of the squashing sound. But in a short time, generally after one, two, or three days, the former condition returned; the eructation again increased, and again vomiting relieved the distressing symptoms. In all cases, the vomited matter was abundant, and contained numerous sarcinæ and torulæ; all the other above-mentioned characters of the vomited matter were also present, so that I may well omit their description, which would be only a repetition of what has been already said.*

* In his communication made to the Heidelberg Medical Society, on June 24, 1865, Friedrich referred to the connection, in most cases, between the formation of combustible gas (hydrogen) under butyric acid fermentation in the stomach, and the occurrence of benign stricture of the pelvis and dilatation after the healing of ulcers, and demonstrated to the

I will only remark, in conclusion, regarding the influence of treatment, that in one of the more recent cases in which the discharge of inflammable gases from the stomach has been observed, the condition of the patient was relieved by the use of charcoal. Since the introduction of the use of the stomach-pump by Kussmaul, it has been used in recent years, and a decided result has been obtained by washing out the stomach with Vichy water, to which carboic acid has been added.

After the preceding article had been written, a new case came under observation in the hospital at Heidelberg, which thoroughly confirmed the observations made above, and also afforded some points of note in regard to the mode of death.

On June 17, 1874, a vine-dresser, aged twenty-five, was admitted; he was said to have suffered during five years from gastric disturbance. The first symptom was cardialgia, generally coming on after meals; he then had frequent rising of the stomach and heartburn. For a year he had violent pain in the region of the stomach, and vomiting, which for a quarter of a year had become more frequent; and during this time he discharged large dark-coloured masses from the stomach. His appetite was diminished, his bowels were constipated, and he had lost flesh and strength.

Objective examination discovered emaciation, strong pulsation in the epigastric region, slight distension and moderate tenderness of the epigastrium. There was no tumour. The stomach was moderately dilated.

During his stay in hospital, he discharged by vomiting, on several occasions, a quantity of chocolate-coloured matter, amounting to several quarts daily; it was frequently tinged with fresh blood, and on microscopic examination was found to contain sarcinae and torulae. During the nine days that he was in hospital, the patient was treated with tannin and opium; to relieve the severe attacks of cardialgia, morphia was injected subcutaneously, and bladders of ice were applied. His condition, however, remained on the whole unchanged, the vomiting continued; the inflammability of the gases discharged by eructation was not ascertained; and within a week after his admission he had several dark-coloured stools.

On the night of June 25, 26, after having had repeated attacks of vomiting and cardialgia during the day, he was seized with collapse and syncope. This passed off, but returned four hours afterwards, the body becoming much distended, and he died.

The clinical diagnosis was, round ulcer of the stomach; and the death appeared most probably due to perforation. The idea that there had been slow hæmorrhage was opposed by the fact that the temperature of the patient on the evening before his death was 98.6° Fahr., and by the suddenness of the death.

The necropsy was made by Professor Julius Arnold three-and-a-half hours after death. The stomach was enormously dilated, occupying the greatest part of the abdominal cavity. The diaphragm was pushed upwards, and the part of the great curvature nearest the pylorus reached almost as far as the symphysis pubis. It lay with its long diameter on the axis of the abdomen; the small curvature being somewhat

to the right of the middle line, and the large one lying to the left against the abdominal wall. The arteries and veins along the great and small curvatures were filled partly with blood, partly with air; and along with them were seen wider channels filled with air (lymphatics).

On puncture of the stomach there escaped a large quantity of gas, which burned with a clear blue flame about half a foot long. The gas in the duodenum and upper part of the small intestine was also inflammable; while that which escaped from the lower part of the ileum (which lay in the pelvis) and the colon extinguished flame.

Besides the combustible gases, the stomach contained a large quantity of dark tar-like fluid; its mucous membrane was remarkably swollen and thickened, had hyperæmic spots, and was covered with a slimy coating. At the pylorus there was a loss of substance, with a sharply defined edge and smooth base; above it, on the anterior wall, was a superficial cicatrix. Besides this, on the small curvature, about an inch from the pylorus, there was a recent superficial loss of substance. The lumen of the pylorus was much contracted. At the lower part of the œsophagus, immediately above the cardiac orifice, was an ulcer about the size of a two-thaler piece, with a very swollen edge and smooth base; it was remarkably deep. Above this was a small superficial loss of substance. Beyond an unusually anæmic state of the brain, nothing of importance was found elsewhere.

The death of the greatly weakened and anæmic patient was thus the result of the sudden distension of the stomach by the inflammable gases, which must have interfered with the respiratory movements, and have still further reduced the already defective flow of arterial blood to the brain, and thus led to fatal syncope. The gases must have entered the gastric vessels from the ulcerated parts, under the enormous pressure which they exercised within the stomach.

FRENCH AFFAIRS.

(From our Paris Correspondent.)

Ungracious as is my self-imposed task of censor of medical affairs in Paris, it is one of increasing usefulness; one, therefore, which I am increasingly moved to undertake, and which I hope you will allow me from time to time to pursue in my small way. It is true that the *Gazette Hebdomadaire* treats me with grandmotherly severity; that the *France Médicale* this week more angrily describes me as 'grincheux et mal léché'; but, on the other hand, the eminently Gallic tone of your journal saves you from the same censure, and I am content to bear it; although, from some inquiries which were made recently, I find that if I were absolutely to unveil myself, some of my excellent colleagues here would arrange for me a 'mauvais quart d'heure.' So our motto must be courage, discretion, and fidelity.

I have been away from Paris for a week, and have not watched the course of events very closely; but I do not see any considerable reason to regret it. After the conclusion of the absurd Bouillaud-Colin incident, by which the Academy became for weeks the subject of interminable disputes and discussions on questions concerning the movements of the heart, as to which everyone, except one or two doting old men, has perfectly made up his mind, there supervened a discussion on the propriety of injecting

meeting, in a dark room, the very remarkable phenomenon of the inflammability of the gases discharged by eructation. The clinical pupils during the session had also the opportunity of observing this rare phenomenon.

chloral into the veins, in lieu of giving it by the mouth. It is difficult to suppose that intravenous injection should have been treated so lightly as it was in this discussion; but of course the result was to arrive at the conclusion, that it is a method which is fraught with dangers, and must be reserved for great emergencies. Then, however, followed a perfectly characteristic shower of twaddle and amplifications. The usual disposition cropped up to treat the method of intravenous injection as a great French discovery; and Dr. Halford, of Melbourne, would have been surprised at the *naïveté* with which intravenous injection of ammonia as a treatment of snake-bite was discussed as a French invention of the most high novelty.

Two discoveries, however, which we have recently made, quite deserve the attention of your scientific readers. M. Gosselin, one of our surgical eminences, and a great friend of some of you English, has made a discovery which certainly ought not to escape your notice. You know, perhaps, that M. Lefort and some others of our younger hospital surgeons were so unpatriotic as to discover that the mortality after surgical operations in our hospitals was, and is, very much greater than in yours. As operative surgery is our *forte*, the accuracy of this disgusting observation was disputed as long as it could be, and is still kept carefully in the background, as our hospitals eschew medical statistics, and the elaborate vital analyses of the hospital population, which all your great hospitals publish, are here either not made or are suppressed. As, however, the facts were not to be disputed, they had to be explained; and the illustrious Velpeau hardly solved the difficulty by convincing himself that the French patients do not possess the 'chair chirurgicale'; and as they have not a surgical quality of flesh, it is, of course, the fault of the joint and not of the carver, if the results are not as satisfactory as might be desired. This conclusion, however, has not been universally accepted without a certain reserve, and it has followed that some adventurous spirits have been looking out for other causes adjuvant to the want of surgical quality in French flesh. (My poor compatriots! not even fit to be cut up!) M. Gosselin then believes he has found it, and it is important that you should know it, because it concerns you almost as much as it concerns us. M. Gosselin, then, has arrived at the conclusion that the cause of the excessive mortality in the French hospitals is, that *there is too much cleanliness* in the wards. This, you see, is a truly French thesis, and M. Gosselin defends it with suitable fire and ingenuity. You are always scrubbing the floors, he says to the sisters of the *salles*, sweeping down the walls, brushing the dust off the curtains, shaking the bed-clothes. Now all persons are agreed that this dust which you are incessantly removing is loaded with zymotic germs. *Let it lie*, therefore. So long as it reposes in peace it is at least harmless; when you fill the atmosphere with it, it flies hither and thither, settles upon wounds, touches upon the mucous membranes, and enters into the system of the patients by the mouth, the nostrils, the air-tubes, and the digestive passages. This is charming, and might be most amusing as satire on the dirty habits of our French hospital guardians, if it were not intended seriously, and if it did not come from a surgeon of serious character and great merit such as M. Gosselin. Your Pagets, Callenders, Holmes, and Bristowes have been preaching a gospel of cleanliness, as the means

of still further improving your excellent results after surgical operation, and the splendid results of Callender at St. Bartholomew's have attracted the attention of the whole of Europe, contrasting as they do with the remarkable success of Lister, at Edinburgh, who has also succeeded in obtaining an immunity from hospital diseases, and a magnificent vital statistic, such as have been hitherto unknown. And then comes M. Gosselin and, 'de cœur léger,' preaches a 'gospel of dirt.' Let the dirt lie, he says, it belongs to the dangerous classes; the less you move it, the less danger you incur. Call a truce with it; give it quiet lodgings, and it will not harm you and your patients. Is not this a true reflection of the causes of our political as well as of our scientific decadence? Let sleeping dogs lie; do not probe below the surface; believe what it is pleasant to believe; think yourselves the bravest, the wisest, the most generous of peoples; and when you have awaked to find yourselves outgeneralled, outfought, outwitted, last in the field and lowest in knowledge, rub your eyes and turn round again to mumble 'Nous sommes trahis,' and to murmur in your dreams, 'Nous aurons la revanche.'

But poor M. Gosselin's patients will never have their 'revanche' with him, at least in this world. If he smothers them in zymes, and powders the walls and the curtains of his *salles* with accumulated fevers and breeding hospital pests, they must suffer, and that uncomplainingly. So I am fain to complain on their behalf—to complain that any man should hardily at this date, and in the face of accumulated millions of facts, proclaim a gospel of dirt as the law of hospital life. And this, too, in France, where neglect of hospital hygiene and of personal cleanliness is already the curse of the wards and the main cause of the existing excess of mortality. I have hardly ever seen an Englishman, after he has been through the *service* of any one of our surgeons, without his expressing to him his horror at the revolting and wicked want of cleanliness; the nonchalance with which brushes, laden with lotions, are applied first to one sore and then to another, from chancrous to gangrenous ulcer, from gangrenous ulcer to simple sore; the carelessness with which instruments are used first for one patient and then for another, without first plunging them into boiling water; the still more disgusting carelessness with which a surgeon will pass his index finger into an abscess or a fistula, and presently, after rubbing it on a *dry* towel, into the mouth of the next patient. The basin and towels, with hot water and soap, which in every English ward stand on every table, and of which the surgeon and the nurse make liberal use, are here wanting. With you, the young dresser, or *interne*, knows well that if he were to use a surgical instrument for two successive patients, without meantime plunging it into boiling water, he would be held guilty of a crime. Here one sees these young men go from patient to patient, with probes and knives, contenting themselves with a hasty rub of the polluted instrument on their dirty aprons. It is so, likewise, with sponges and camel-hair brushes. It is to this and to the filthy closets, the greasy dressings, and the want of pure air and abundant water in the wards, that our hospital mortality is to be traced. It was thus that the American surgeons in their hospital during the siege saved their patients, while in our hospital at the Grand Hotel *every case of amputation died*. They worshipped cleanliness. Everything which came from a patient, or which had touched a patient,

was either burnt or plunged in boiling water. Everything was freshness, purity, cleanliness itself. The dressings were light and cleanly water-dressings. There were no greasy abominations thrust between the flaps, on the pretence that union by first intention could not be got, and therefore need not be tried after. You never saw bundles of filthy reeking charpie, impregnated with yellow grease, with decomposing blood and pus pulled out from a cavernous wound; the dressings were light, they were antiseptic, cleanly, and *frequently changed*. There is nothing more distressing to my mind, after having had some experience of English and American hospitals, than to go round the ward with one of our eminent French surgeons; to see him removing dressings reeking with filth, without sternly reproving his *internes* for allowing them to get into that poisonous state; to see him stuffing greasy charpie into wounds, and bandaging it there to putrefy and corrupt for twenty-four hours, instead of lightly bringing the surfaces together, which only ask to be allowed to unite, and dressing the wound as every other civilised nation does, with light and clean water- or carbolic-dressings, frequently changed; to see him use the same probe for a dozen wounds, the same brush for a dozen sores. It makes my heart ache for the patients; and it humiliates me, for I know that it is not from any inherent defect of earnestness or intelligence, that our surgical wards are the bywords of Europe, but because, in our vanity and ignorance of the world of science, we have gone on in the ways of our grandfathers. Talk to an average Frenchman about Liston and his introduction of water-dressings, and of union by first intention, and he will laugh at you, and tell you there is no such thing; that it has all been tried and failed; that he never heard of Liston, but Nélaton tried it, and could not succeed. Or a more erudite man will tell you that Liston only copied some Frenchman, who in the fifteenth century sprinkled a wound with a syringe, and that Liston and Lister (who were brothers, he believes) were very clever men, but deficient in science, and have not presented any memoirs on the subject which can compare with those of M. Guérin (who has got hold of the wrong end of Lister's stick, and thinks that to wrap a stinking wound in cotton-wool will suffice to heal it). No doubt M. Guérin's cotton-wool will save the patient from the worse horrors of ordinary French surgery, and is a point gained in his favour; but it is truly shocking—to return to the point from which I started—that, at a time when every sound observer knows that the first requisite in French hospitals is a more scrupulous observance of cleanliness, M. Gosselin should come forward to preach a 'gospel of dirt.'

MACLEOD ON THE ROYAL NAVAL LUNATIC ASYLUM AT YARMOUTH.

The report issued by Dr. Macleod is very creditable and complete, and speaks volumes for the advantages of a small over a large asylum, seeing that in the former a much better individual knowledge of the patients is acquired and greater personal attention is paid to them. The advantages and defects of the institution are brought freely forward, and in such a way that, whilst inviting criticism, they disarm hostile remarks. It is perhaps questionable whether a blue-book is the proper place for bringing

forward the particular effects of enemata, sedatives, etc., for the printing and the paper are done at the expense of the public, who neither understand nor care about such matters; and the most recently expressed opinion of the Medico-Psychological Association is, that these things are better left to the special province of strictly medical journals. Dr. Macleod has enlarged on the usual symptoms and treatment of various forms of insanity in a manner that shows him to be well acquainted with routine asylum treatment; but many of his statements might have been taken for granted, since they come within the scope of the most ordinary observation, e.g. the fact that paralytics 'require eight or nine changes of clothing during the day,' that 'men with paralysis of the insane get bed-sores,' etc. One method that he recommends of administering medicine in troublesome patients is, however, so questionable that we are compelled to dwell on it. Dr. Macleod says that 'when they refuse medicine it is given by the nasal or œsophageal tube.' Now why not employ subcutaneous injection? Most, if not all, sedatives can be given subcutaneously, and purgatives or emetics can be more easily placed on the tongue, and with better chance of action, than administered by the stomach-pump. Again, Dr. Macleod 'gives it as his opinion that' forced feeding (stomach-pump) in general paralysis 'only hastens the fatal termination.' Has any one denied this? Who would now-a-days dream of feeding a general paralytic forcibly? The capriciousness of their appetites is well understood, and a man who refuses food at a certain meal-time will most assuredly take it at some other. We have an ordinary routine for breakfast, dinner, and supper; but the insane are above routine, and should be allowed a little choice as to the times they prefer for filling their stomachs. Again as to the so-called bed-sores; what is the use of saying that 'a bed-sore arose, not from neglect, but from constitutional symptoms'? We give the establishment credit for not neglecting patients, but a little cotemporaneous reading would have made the author acquainted with the fact that 'local gangrenes' recur in the stage of paralytic dementia, quite unconnected with the question of their being free from excoriation by urine. *Qui s'excuse s'accuse*; and it does look as if Dr. Macleod were combating some unseen foe, and, by accounting in a certain way for some undesirable appearances, neglected to shield himself under a protection which already exists. In spite of all precautions, one suicide occurred from hanging. The medical appliances used seem to have been tolerably successful, but nothing is said of the employment of ice in the epileptoid convulsions of the final stage of general paralysis, whilst bromide of potassium is largely praised as a remedy for 'this distressing symptom.' Now it must be remembered that these epileptiform convulsions are never very long in duration, and are attended with marked congestion of the skin; and that universal experience has shown the efficacy of ice in relieving the symptoms, whilst potassic bromide requires a certain length of time for its operation, and has a directly congestive action on the skin. The convulsions of epilepsy and the epileptiform attacks of general paralytics differ in many respects, and before the same remedy is applied to them it must be shown that there is a *prima facie* probability that good may be expected. A correct view of therapeutics would lead to a directly opposite opinion as to the advantages of potassic bromide. That 'depraved habits are at times persistent and

troublesome' we quite allow ; but that 'black vomit before death' necessarily shows 'degenerations of the fluids and solids' we must demur to.

The appended tables of admissions, deaths, and recoveries have all the appearances of being carefully compiled.

MEDICINE.

DE LATOUR ON MEDICAL THERMOMETRY.—No. 82 of *L'Union Médicale* (July 9, 1874) contains an article on 'Defects in the Instruments and Methods employed to determine Animal Heat,' by Dr. Robert de Latour, with a description and woodcut of the thermometer employed by him for more than thirty years. He states that many practitioners are deterred from taking temperatures by the difficulty they find in reading the small figures on the stem of the ordinary pocket thermometer, and the equal difficulty of distinguishing the column of mercury from the glass. Nearly half an hour, he says, must be lost, whilst the mercury is rising to perhaps 20° C. (36° Fahr.) above the atmospheric temperature. If the doctor attempt to warm his thermometer at a candle, ten to one he breaks the instrument by the sudden expansion of the mercury. Meanwhile, valuable time is lost, for, though the pulse may be taken, respirations counted, and many questions asked, yet neither auscultation nor percussion, nor other modes of physical examination, can be conveniently practised whilst the temperature is being taken. These inconveniences, he thinks, are obviated by his own clinical thermometer, the peculiarities of which are as follows. It consists of a tube bent at a right angle, and so forming two branches—one of which is quite free and horizontal, terminating in an olive-shaped extremity for the axilla ; this branch measures $3\frac{3}{10}$ inches ; the other, 4 inches long, is attached to an ivory scale, with clearly marked divisions of degrees (C.) and tenths of a degree. This extremity terminates in a bulbous reservoir, for the sake of security against the sudden expansion of the quicksilver. This reservoir also serves to re-establish the continuity of the mercurial column when it has been accidentally broken, since it is only necessary to warm the instrument so as to drive some the mercury into this reservoir, and the column again becomes united. For the sake of legibility and portability, he graduates this scale from 34° C. (93.2° Fahr.) to 42° C. (107.6° Fahr.) only, and vindicates his rejection of higher degrees by affirming his disbelief in the occurrence of such temperatures, except in the death-agony, or as *post mortem* phenomena. He says he cannot boast of millions of observations like Wunderlich, but, on the other hand, his observations are personal (*i.e.*, not done by deputy), and he has never met with such temperatures in his practice. He affirms it to be almost an axiom in physiology that no animal can survive its blood being heated 5° C. (or 9° Fahr.) above its normal heat ; a result which he attributes chiefly to increased rapidity in the capillary circulation, whilst the large veins and right side of the heart are unable to keep pace ; hence increased pressure, stasis, and finally stoppage of the heart. As special recommendations of his thermometers, he says that they can be warmed with safety before use ; do not require more than a minute *in situ* ; are easily read ; the mercurial column, if broken, can be joined easily again ; and they themselves are not easily broken.

His first description was published in 1842, and subsequent ones in the *Revue Médicale*, *Union Médicale*, *Tribune Médicale*, etc. Lastly, he accounts for the want of appreciation shown by his countrymen, by the fact of the French origin of his invention. He anticipates that it will be warmly welcomed, if it should be reintroduced, some time hence, as a German discovery, since everything German is hailed with delight, and is sure to be both popular and efficient ! The lettering and explanations affixed to his scale are as follows :—

| Lettering. | Cent ^{de} . | Fahr. | Explanation. |
|------------|----------------------|--------|--|
| T.M. | 41.5° | 106.7° | Maximum temperature. |
| F.E. | 39.5° | 103.1° | Truly febrile temperatures. |
| F.S. | 38° | 100.4° | Temperatures symptomatic of local lesions. |
| T.N. | 36.5° | 97.7° | Normal temperature. |

We are promised a continuation of this paper.

[As regards the instrument figured and described by Dr. De Latour, the reporter thinks there are two positive merits, viz., the olive-shaped extremity for the axilla, and the large reservoir at the other end. It would seem, too, that priority must be accorded to Dr. De Latour for the idea of a curved instrument, which the reporter has not found so convenient in practice as the straight tube, even in the modified form of Dr. Aitken's and Mr. Casella's instrument. It does not appear from the description that this French thermometer has any index, although there seems no reason why it should not be so furnished. The index, and the use of a reading-glass or pocket-lens, appear to the reporter to obviate many of the objections to the smaller clinical thermometers—although larger instruments undoubtedly allow the scale to be more finely divided, and there is rather less risk of errors in graduation. He feels it only right, however, to strongly protest against the idea of one minute being long enough with any of our present instruments, however delicate. This short period of observation doubtless explains Dr. De Latour's scepticism as to high temperatures in non-fatal cases. These, however, do not now rest on the testimony of one observer, however eminent, since Dr. Wilson Fox's cases have been supported by the publication of others. Dr. De Latour fixes his normal point too low—an error which probably arises from taking observations on convalescent, rather than on truly healthy people. The reporter believes the testimony for 37° C. (98.6° Fahr.), as the average normal point, to be overwhelming.—*Rep.*]

W. BATHURST WOODMAN, M.D.

HAMMOND ON THE CAUSE OF HYDROPHOBIA.—The *Fancier's Gazette* of July 25, 1874, contains an extract from an article on this subject in the *New York Weekly Tribune*.

Mr. Wm. M'Cormick, who was a butcher, was bitten by a small dog on the hand. The wound seemed to be only a scratch, and was not further noticed. About a month later, Mr. M'Cormick felt a peculiar creeping sensation, coming up his back and spreading over his shoulders and back of his neck. He also felt faint, and was provided with a glass of water. On taking the glass in his hand and attempting to drink, his teeth closed on its edge, his lips became purple, and his face presented the appearance of a person asphyxiated by choking. Powerful narcotics were administered, but without effect, and he died the next day. The day after,

Drs. W. A. Hammond, Meredith Clymer, Hudden, and others, met to discuss the case, and make a *post mortem* examination. Dr. Hammond was of opinion that the disease was a true nervous lesion, of either the brain, spinal cord, medulla oblongata, great sympathetic system, or of all of them. Dr. Clymer contended that there was clearly blood-poisoning.

On examining the brain, the membranes were found to be intensely injected, the small vessels being distended to their utmost, and small points of a scarlet colour being everywhere observed. The sinuses were full of blood. The entire surface of the brain was engorged. Dr. Hammond remarked that, whatever might be the seat of the disease, the inflammation had extended to the brain. This had produced the coma that at times overcame the patient. The general opinion of the assembled physicians was that the seat of the disease was in the medulla oblongata.

To Dr. William A. Hammond was entrusted the work of ascertaining whether any structural changes hitherto undiscovered would reveal a true lesion. The medulla oblongata had been carefully removed and placed in alcohol. The pneumogastric nerve was exposed on the left side of the neck, and a piece of it carefully cut out and placed in another bottle of alcohol. The medulla was cleaned of every portion of membranous substance, and then immersed in a weak solution of bichromate of potash.

Four days later, Dr. Hammond began his observations. The first section was made through the spinal accessory nerves, where the filaments pass from the medulla. The reason that this part was first brought under observation was, that the greater force of the disease seemed to be expended on the muscles of the throat, larynx and pharynx. The first spasms were those of the constrictor muscles of the throat. This was brought on by M'Cormick's attempting to drink a glass of water. The attending physicians, at the *post mortem* examination, were astonished at the healthy appearance of the larynx and pharynx internally, while the congestion and external inflammation amounted almost to engorgement. When this section was properly adjusted, the cause of this condition of the throat was evident. At different points in the white and grey matter of the medulla there were distinctly seen, when highly magnified, black spots of irregular shape and various sizes, indicative of extravasated blood. At the origin of the spinal accessory nerves this appearance became more marked, and the evidence that the part was the seat of the disease was as positive as anything could be. Other sections were made, and the same appearances were plainly to be observed. A section through the medulla oblongata at the origin of the filaments of the pneumogastric nerve exhibited, when highly magnified, the same dark-irregular spots. In this section, as in that including the spinal accessory nerves, the greatest diseased action was evident about the origin of the nerve-filaments, though the spots could also be plainly discerned in the grey and white matter of the medulla oblongata.

J. LOCKHART CLARKE, M.D.

M'CREA ON STRAPPING THE CHEST IN PHTHISIS. Dr. M'Crea (*Lancet*, July 18, 1874) describes a method of strapping the chest in phthisis, employed by him at the Belfast Dispensary. The use of other remedies is at the same time not interfered with. The plasters used in strapping are able to bear the

strain of walking and talking, so that gentle exercise and conversation are not forbidden. Dr. M'Crea has principally used emplastrum roborans spread on swan's down. The sheet, which is half a yard wide, is to be cut into transverse strips. Each strip is eighteen inches long. The plasters should be only very slightly heated. The first strip runs up the back in the space between the spinal column and the posterior border of the scapula on the affected side, its starting point being well below the level of the inferior angle of the scapula. It is to be applied gradually and deliberately, every portion being well rubbed in before the next portion is brought into contact with the skin. It is to be carried over the shoulder and down the front of the chest. In rounding the shoulder it is to be pulled tight, and held so while it is being, bit by bit, brought into contact with the front of the chest, the chest just at this period being in the act of strong expiration. The next strip, which is horizontal, commences at the spine, crosses the posterior end of the first strip, passes under the axilla, and on towards the sternum. It is also to be applied deliberately and with friction. As it is rounding the chest, it is to be pulled tight, the patient at the same time making a forced expiration. Other strips are to be applied in a similar manner—vertically and horizontally, until it is judged that a proper grasp of the chest has been obtained. The scapula is to be avoided as much as possible. Some of the horizontal strips should cross the sternum, and some the spine. A large rectangular piece of plaster should now be applied, occupying the interscapular space and reaching down to the last dorsal spine. Another squarish piece is to cover the front and upper part of the chest between the clavicles and mammæ. Finally, the whole is to be well rubbed in all over. The patient is to sit quiet for a few minutes before dressing. Dr. M'Crea covers more of the lung than the portion apparently diseased. In a fortnight, a reapplication will probably be required. This will give a good opportunity for a careful examination of the condition of the lung. While the plasters are still on, the indications of the thermometer will be most valuable. If there be an exacerbation of the symptoms, particularly of the cough, dyspnœa, or pain, if the temperature rise, or if the plasters be obviously slack, new ones are to be applied. Dr. M'Crea states that this method of treatment is followed by an immediate and marked diminution of the cough, cessation of pain, relief of dyspnœa, and reduction of temperature, and that the patient usually expresses at once a feeling of great comfort. Dr. M'Crea feels so satisfied with the results of the numerous cases in which he has tried this method, that he gives it the first place among all the remedies for phthisis.

H. SUTHERLAND, M.D.

GOOPTA ON SUICIDE AND LUMBRICI.—The *Indian Medical Gazette* for July 1, 1874, contains a brief paper by Assistant-surgeon Gooro Doyal Doss Goopta, in charge of the medical dispensary at Tangail, in which he arrives at the conclusion that lumbricoid worms may be an exciting cause of suicide. Such deaths were more common among the Mussulmans than the Hindoos. Round worms were found in twelve out of eighteen bodies of suicidal hanging examined; that is, in two-thirds of the total number, or in about 67 per cent. The greater number of those who committed suicide were of the

age at which the round worm is common. There were only two above twenty-five years of age, and in these two worms were not found. Of the remaining sixteen who were below twenty-five years of age, in four only were no worms found, but in two of these [he says] I am not sure that the intestines were carefully searched. When the worms bring on irritation by reflex action the sufferers turn peevish and low-spirited, consequently they can scarcely withstand any trifling reprimand or other kind of correction. To them these very insignificant causes become so painful that they immediately resolve to relieve themselves by committing suicide, hanging being the mode of death generally preferred and adopted.

T. S. COBBOLD, M.D.

DISEASES OF CHILDREN.

CLARUS ON APHASIA IN CHILDREN.—Dr. Albrecht Clarus (*Fahrbuch für Kinderheilkunde*, vol. vii. p. 369), analyses fifty cases, two of them noted by himself, and the rest drawn from published sources.

1. *Aphasia in Idiots and the Deaf and Dumb*.—1. Congenital idiocy is not discussed. 2. Acquired idiocy and aphasia, consequent upon chronic hydrocephalus, encephalitis, frequent epileptic fits in infancy, syphilitic affections, and atrophy of the brain in general marasmus. In aphasia of the last two kinds, the prognosis is not bad; in cases of the other kinds, only a certain degree of improvement can be expected. Hughlings Jackson has pointed out that aphasic idiots who are not deaf, can sometimes sing words which they cannot speak. 3. Deaf-dumbness is not discussed. 4. Lastly, Clarus gives three cases of congenital aphasia, unconnected with defective intellect or with deafness: but in one of these cases the right side of the body was relatively atrophied; and in another there was possibly a slight degree of idiocy.

II. *Aphasia after Acute Diseases*.—1. Typhoid fever is that which is most frequently followed by aphasia; namely, in twelve cases. Ten of these were boys. Eight were between eight and eleven years of age, three between three and five, one was thirteen. Four became aphasic during convalescence, one in the fourth week, two in the third, one in the second, one on the eighth day, the others uncertain. As to the prognosis: one patient died on the eighteenth day of the fever, and on the tenth day of the aphasia; at the *post mortem* examination there were no naked eye lesions of the brain; one patient became perfectly speechless and hemiplegic, but this, no doubt, was a case of embolism of the brain, consequent upon valvular disease of the heart; all the other cases recovered in about three weeks. The reporter cannot help quoting a passage from Heberden upon this point: 'In febribus longis et periculosus pueri solent tandem obmutescere, et vox per dies aliquot supprimitur postquam extra omne periculum fuerunt; semper tamen redit, neque omnino triste augurium censendum est.' (*Comm.*, cap. 37.) 2. There were two cases of aphasia after measles. A girl aged eight became suddenly comatose, during the eruptive stage, and remained so for three days; afterwards she was left aphasic for a few more days, and then recovered. A boy, at the end of measles, was seized with convulsions and coma; he was left blind, deaf, and speechless; his hearing

returned, but he remained blind, became hemiplegic, quite demented, and so died. 3. Small-pox was attended by aphasia in one case, a child aged nine; temporary aphasia after coma came on in the maturation stage. 4. A boy of eight, dropsical after scarlet fever in the sixth week, had convulsions and coma, followed by right hemiplegia and aphasia; the hemiplegia passed off, the aphasia remained.

III. *Aphasia after Acute Disease of the Brain*.—1. Embolism, five cases (one very incompletely noted). In the four others there was valvular disease of the heart. Three were complicated with right hemiplegia, ending in death. In one case there was no hemiplegia; speech was regained in twenty-four hours. 2. Traumatic aphasia was met with in five cases. 3. Meningitis occurred in one case; partial recovery. 4. Tubercular meningitis was present in one case. 5. Abscess of the brain was found in one case, in the left anterior lobe.

IV. *Aphasia after Chronic Disease of the Brain*.—1. Tubercular tumour, four cases. 2. Hydatid tumour, six cases. In five of these cases the tumour did not exist in the left cerebral hemisphere; the author dwells upon this point.

V. *Aphasia in Neuroses*.—1. General convulsions, one case; pathology very uncertain. 2. Hemispasmus of the right side, two cases, narrated by Dr. Hughlings Jackson (*St. Andrew's Med. Assoc. Trans.*, vol. iii. p. 162). 3. Chorea, three cases; prognosis favourable. 4. Worms, two cases; recovery.

SAMUEL GEE, M.D.

BOUDON AND CHOUPEE ON THE USE OF IPECACUANHA ENEMATA IN INFANTILE CHOLERA AND PHTHISICAL DIARRHŒA. — Ipecacuanha enemata have been tried from time to time in divers diseases of the intestines. Graves and others have done so, but no one seems to have studied this method of treatment with any care. M. Boudon has taken up the subject of late, and the results of his experiments are published by M. H. Choupee (*Bulletin Général de Thérapeutique*, June 15, 1874).

I. *Method of Treatment*.—Take 308 grains (20 grammes, nearly three-quarters of an ounce) of bruised ipecacuanha root; and 18 ounces (500 grammes, nearly a pint) of distilled water. Make three successive decoctions (for ten minutes each) in one third of the water. Mix; give half of this quantity for an enema; or, in the case of a child, a quarter only. For an adult, add eight or ten drops of tincture of opium (*British Pharmacopœia*—five or six drops of Sydenham's laudanum). In some cases the quantity of ipecacuanha used has been double that given above, namely 40 grammes. Two enemata are to be given daily; one in the morning, two hours before breakfast: one in the evening, three hours after the last meal. Nausea sometimes follows; vomiting never. The aim of this method is to avoid producing vomiting; it is not supposed that the local effect of the ipecacuanha upon the rectum has much to do with the results. It is seldom that any inflammation of the rectum follows the enemata; and when it does, it passes off as soon as the enemata are left off. Reasons are given for believing that it is the emetina of the injections which does good, and not the opium or the minute quantity of tannin dissolved in them.

II. *Infantile Choleraic Diarrhœa*.—Of five cases, four recovered after from three to twelve enemata; one died, very likely in consequence of being wrongly fed during the treatment. In no case was vomiting produced. M. Choupee thus sums up. Ipecacuanha

seems to act powerfully against the diarrhœa of infants; and when given in enemata, which do not provoke the vomiting which often follows when ipecacuanha is given by the mouth, the enemata can be continued for a long time without weakening the patient, and therefore may be tried in obstinate chronic diarrhœa.

III. *Phthisical Diarrhœa*.—Of seventeen cases, cure took place in thirteen, amendment in two, failure in two. In one case the diarrhœa, which was unaffected by enemata of ten grammes each, was stopped when the quantity of ipecacuanha used was raised to twenty grammes. Most of the patients were in an advanced stage of phthisis; one, whose diarrhœa had lasted ten months, required thirty-four enemata before it was cured.

SAMUEL GEE, M.D.

FINCH ON A PECULIAR AND DANGEROUS AFFECTION OF THE RESPIRATORY ORGANS IN CHILDREN. Dr. Finch (in a pamphlet published by Harvey, Colchester) relates five cases of a laryngeal affection in children, which he attributes to the pressure of an enlarged thymus gland upon the recurrent laryngeal nerves, causing paralysis of the dilators of the glottis. The symptoms observed were persistent hoarse stridulous respiration, lasting with more or less complete remissions for months, or even years. There was an absence of all febrile symptoms. In all the cases a projection of the upper portion of the sternum was noted, and in three some enlargement of the cervical glands. Two cases were fatal from the gradually increasing difficulty of respiration, and in one of these a *post mortem* examination was made. The thymus gland was found to be greatly enlarged, occupying the upper portion of the anterior mediastinum, from the second intercostal space to near the lower border of the cricoid cartilage. The lining membrane of the larynx and trachea was injected and darker than natural, and adhering to the lower half was much tough dry mucus. In the three remaining cases, recovery from a succession of intermittent attacks had taken place.

[Numerous cases of hypertrophy of the thymus gland have been recorded in which there was no spasmodic affection of the larynx; and it has been shown that the theory of Kopp, that 'laryngismus stridulus,' the so-called 'thymic asthma,' was dependent upon the irritation or pressure of an enlarged thymus, was incorrect, and that in the majority of cases of laryngismus no such enlargement of the gland exists. It is to be regretted that the relations of the enlarged thymus to the laryngeal nerves was not ascertained in the *post mortem* examination recorded by Dr. Finch.—*Rep.*]

W. B. CHEADLE, M.D.

SURGERY.

SCHWARZ ON URETHRO-RECTAL FISTULA FOLLOWING AN ABSCESS OF THE PROSTATE.—M. Schwarz, interne in the Maison Municipale de Santé, reports, (*Union Médicale*, July 2, 1874), the following case, which was under the care of M. Demarquay. The patient, a baker, twenty-two years old, was admitted January 6, 1874. Four months before he had gonorrhœa, and was treated by injections of acetate of lead and diuretic medicines. The discharge lasted fifteen days and then ceased; the patient had difficulty in passing urine, then retention of urine.

A catheter was introduced and retained; he was feverish, had much pain in the perinæum, along the urethra, and in the penis. When the catheter was withdrawn, there was a discharge of pus from the meatus. He did not know whether at that time there was matter in his stools; but from that moment every time he passed urine part of it issued from the rectum. In the intervals of micturition no urine escaped *per anum*.

When admitted, he voided as much urine *per rectum* as *per urethram*. The diagnosis was, abscess in the prostate gland opening both into the urethra and rectum, a fistulous passage connecting the two openings. The day after admission an enema was administered, and he was examined with the American speculum. [The reporter is not quite certain what form of speculum is meant by the term 'American,' as there are several kinds of anal specula used in America; but probably Bozeman's was the one employed.—*Rep.*] There was seen, at the level of the anterior edge of the prostate, an elevation, or papule, in the centre of which was an orifice surrounded by small vegetations; into this orifice a stylet passed obliquely from below upwards, and from before backwards. On passing a metallic sound along the urethra, it could be felt by the probe in the sinus. An injection into the bladder did not pass into the rectum. After the examination, baths and emollient enemata were prescribed, a catheter was kept in the bladder, and the fistulous track was cauterised with tincture of iodine. It was found impossible to retain the catheter, in consequence of the suffering it caused. On the patient passing urine in the presence of the surgeon, it was found that about one third of the urine issued from the anus; and, on introducing the speculum into the rectum, the urine could be seen trickling from the orifice in the little pimple already described. No benefit resulting from the treatment, the sinus was cauterised with nitrate of silver four times, at intervals of seven, four, and six days. Improvement followed this, less urine passing by the anus; but this amelioration of the symptoms did not continue, and a fortnight later the whole fistulous track was cauterised by means of a platinum-probe reddened by the galvanic battery. Two strong cauterisations were employed. The patient did not suffer any pain from the operation. A catheter was again introduced; but it could not be kept in. At first the urine passed in much less quantity *per anum*; but when the slough caused by the cautery separated, it again flowed very freely. This only continued for a short time, and gradually the discharge of urine from the rectum diminished, until, thirty-three days after the operation, only about one-eighth of the whole quantity of urine was passed abnormally. Nitrate of silver was re-applied through the speculum to the spot whence pus could be seen to ooze. The result was good; and in a fortnight nearly all the urine passed through the urethra. Three months after, the patient left the hospital; he continued quite well.

M. Schwartz makes the following observations on the case.

Recto-urethral fistulæ are rare, and they arise from divers causes. Among the most frequent may be mentioned abscess of the prostate; more rarely they may result from abscess of Cowper's glands. These abscesses, the consequence most frequently of blennorrhagia, open into the urethra and into the rectum. The sinus, unceasingly irritated by the foreign matters which pass into it, does not close,

and in this manner the fistula arises. This accident, says M. Demarquay, most often follows those cases of gonorrhœa which are treated too heroically at their onset with balsams and injections. In these fistulæ, all the varieties that occur in ordinary perineal fistula may be found; the sinus may be more or less oblique, more or less sinuous, and from the principal sinus other secondary tracks may diverge. The seat is most frequently, as shown by the etiology, the region of the prostate gland; and next, the membranous part of the urethra.

An interesting point in this patient was, that when he had a seminal emission, the fluid all passed by the urethra, and none by the anus; this clearly showed that the urethral fistulous orifice was situated between the openings of the ejaculatory canals and the neck of the bladder.

The diagnosis of urethro-rectal fistula is made from the urine escaping from the anus at the moment of micturition *only*. In the case of vesico-rectal fistula, the flow, so to speak, is continuous. The prognosis, as regards cure, is always unfavourable; because, though the surgeon may frequently succeed in diminishing the calibre of the sinus, he very rarely succeeds in obliterating it completely. Under any circumstances, and whatever treatment may be adopted, the fistula fills up and heals but very slowly. Among the most important methods of treatment may be mentioned, cauterisations with the hot iron, divers caustics, injections, tincture of iodine, and, in some cases, section of the track.

WM. ALLINGHAM.

MC GUIRE ON DRAINAGE IN OBSTINATE CHRONIC INFLAMMATION OF THE BLADDER.—Dr. Hunter McGuire reports (*Virginia Medical Monthly*) a case of 'chronic inflammation, and probably ulceration of the bladder,' of eight years' duration, successfully treated by drainage; but, instead of effecting this by opening the vesico-vaginal septum, as done by Simpson, Emmet, and Parvin, he introduced a piece of India-rubber tubing, the portion of which to be introduced into the bladder was perforated by a shoemaker's punch, with holes half an inch apart. A straight silver tube was first passed into the bladder, and the tubing introduced through it; the silver tube was then withdrawn, and the caoutchouc one secured in place, and the free end put into a bottle to catch the urine. A vaginal suppository of morphia and belladonna was introduced. The catheter was removed and cleaned, a new one substituted whenever necessary, and the vaginal suppository was also repeated every twelve hours. Afterwards Dr. McGuire substituted a large silver catheter, nearly straight, with a large vesical opening for the India-rubber tube. At the end of six weeks an India-rubber bag was attached to the free end of the catheter, so as to allow the patient to get up and walk about. This treatment was continued for four months, when the tube was removed from the bladder. There was for some time afterwards incontinence of urine, but the bladder gradually regained its healthy power; and eight months after the commencement of the treatment the patient could retain her urine for about three hours, and void it without pain; and, except the increased frequency of micturition which was growing less, the patient was reported to be well.

CHEEVER ON THE SURGICAL TREATMENT OF NASO-PHARYNGEAL POLYPI.—Dr. David W. Cheever states (*Boston Med. and Surg. Journ.*, June 4,

1874) that after a thorough review of all the measures adopted to remove naso-pharyngeal polypi, he feels justified in drawing the following conclusions. 1. The excision, partial or complete, of the upper jaw is applicable only to the removal of tumours which grow from, or are attached to, some portion of that bone. 2. Tumours having their origin either in the sphenomaxillary fossa, the posterior nares, or the body of the occipito-sphenoid bone, can be attacked and completely removed by one of the operations for displacing the upper jaw, or the nose. 3. In this second class of cases, to remove any portion of the bony structures of the face, when they are unaffected by disease and could be displaced and restored, is to cause a needless mutilation, and is contrary to sound principles of conservative surgery. 4. For tumours in the sphenomaxillary fossa, Langenbeck's major operation is applicable. 5. For the growths in the posterior nares and top of the pharynx, Ollier's operation by displacing the nose; or Huguier's operation, modified by keeping the vascular connection of the palate and pterygoid processes unbroken, will either of them prove sufficient to eradicate the disease. 6. In very large tumours, there is no reason, *à priori*, why the operation of displacing the whole upper jaw should not succeed.

ANDREWS ON THE RESTRAINT OF HÆMORRHAGE DURING OPERATION IN THE MOUTH.—Dr. E. Andrews recommends (*Medical Examiner*, April, 1873) the following procedure, suggested to him by Dr. Ira Manly, of Markezan, Wisconsin, to overcome the difficulties encountered from hæmorrhage in operations in the mouth.

The patient being first etherised in the ordinary way, the mouth is held open by an instrument devised for the purpose by Dr. Andrews, and then the spray from the ether-spray apparatus is to be directed upon the roof of the mouth, but not with such intensity as to produce freezing. The cold thus produced contracts the vessels, so that Dr. Andrews was able to perform uranoplasty with comparatively little delay from hæmorrhage or accumulation of mucus. At the same time, the patient constantly inhaling the spray, the anæsthesia was steadily maintained.

MATERIA MEDICA AND THERAPEUTICS.

FALCK ON THE ACTION OF STRYCHNIA.—F. A. Falck (Volkmann's *Sammlung Klinischer Vorträge*, no. 69) says that strychnia is absorbed and acts most quickly when injected into the blood, more slowly from the subcutaneous cellular tissue, rectum, and conjunctiva, and more slowly still from the stomach. Absorption will occur through the lymphatics, even when all the vessels of the part to which it is applied have been carefully ligatured. It is often supposed to be absorbed from the bladder, but, according to the author's experiments, this is not the case. Many cases of strychnia-poisoning are either suicidal or homicidal, but not a few are accidental. Most of these are due to apothecaries either dispensing larger doses than have been prescribed, or substituting strychnia instead of other medicine. Some are due to patients taking too much of the prescribed medicine; but others are due to the fault of the

physician, who has either prescribed too large doses, or overlooked the cumulative action of the remedy, or prescribed badly. In one interesting case of the last sort, the physician ordered nitrate of strychnia in solution with too small a quantity of solvent. The strychnia, consequently, formed a sediment at the bottom of the vessel, and, on being swallowed, caused the patient's death. In another case, a most instructive one, nitrate of strychnia was prescribed with iodide of iron in solution. The iodine combined with the strychnia, and the sparingly soluble iodide of strychnia formed a sediment, which, when swallowed, caused death. A curious case of poisoning occurred in the person of a doctor in Berlin, who had received a quantity of arrow-poison from Java. He wished to ascertain its physiological action, and, instead of experimenting on animals first, he swallowed three grains of it himself. For a wonder he recovered, the substance containing no less than 60 per cent. of strychnia. The symptoms of strychnia-poisoning in man are first, quickened respiration, and afterwards, convulsions of a tetanic character. Sometimes there are general convulsions, but no tetanus. The shortest time in which tetanus has occurred is five minutes, and death in ten. The longest time is tetanus in two-and-a-half hours, and death in six. Where recovery takes place, the convulsions may last twelve hours. The symptoms are similar in mammals, birds, and batrachia. In snakes and white fish there is disturbed respiration, with quivering. In regard to the action of strychnia on single organs, it has been found that it does not paralyse the inhibitory centres of Setschenow; it stimulates the vasomotor centre, causing contraction of the arteries and increased blood-pressure; it renders the olfactory and optic nerves more sensitive, increasing the sense of smell, and the sharpness of vision, as well as enlarging the field of vision for blue and red. In poisonous doses, it produces hyperæsthesia of the retina in dogs. The pupil is dilated to its maximum during the tetanic convulsions, and is normal in the intervals. Strychnia has little action on the heart. It lessens the power of the blood to absorb oxygen. It slightly raises the temperature of the body. It causes contraction of the spleen, and acts upon that organ through the splanchnics. It is said to increase the secretion of urine. When given to a pregnant animal, it exerts but little action on the foetus in utero. According to the author, the common idea that strychnia acts primarily on the spinal cord is erroneous. On the contrary, it acts primarily upon the brain, its action being exerted on the vasomotor centre; on the inhibitory centre for the heart; on the respiratory centre so powerfully, that the irritation is propagated from this to the whole system of voluntary muscles; and lastly, on the reflex apparatus of the spinal cord. These actions excite secondary reflex stimuli, starting from the spinal cord and associating themselves with the cerebral ones. After this has lasted some time, the blood becomes poor in oxygen, and this deficiency of itself acts somewhat like strychnia and the poisoned animals die of asphyxia. The largest fatal dose of strychnia is four milligrammes of the nitrate in a child, and between fifteen and thirty of the sulphate in an adult. In mammals 0.6 milligrammes of nitrate of strychnia per kilogramme of body-weight is a fatal dose; for birds 2.0 milligrammes, for frogs 2.1 milligrammes, and for white fish about ten milligrammes. Frogs therefore require a larger dose than mammals instead of being much more susceptible to its action as is generally supposed. All salts of strychnia have

almost exactly the same action. After reviewing all the remedies hitherto proposed for poisoning by strychnia, the author concludes that the treatment, if convulsions have not set in, is to empty the stomach by emetics or the stomach-pump, to wash it out with decoction of galls, and combat the convulsions by chloroform. If convulsions have already begun, chloroform must be given at once and the intestinal canal emptied afterwards. When the poison has been absorbed from a wound, it should be washed, excised, or cauterised. Death from strychnia cannot be diagnosed with certainty from *post mortem* appearances. The best method of detecting its presence in the stomach or elsewhere is that of Dragendorff. Strychnia is not destroyed by putrefaction of the tissues. Its chief medicinal uses are in paralyses, motor or sensory. It is also employed in chorea, epilepsy, and writer's cramp, dyspepsia and constipation. The best form is pills, or, still better, subcutaneous injection. The dose for use in the latter should not exceed eight milligrammes.

T. LAUDER BRUNTON, M.D.

PARVIN AND OTHERS ON THE TREATMENT OF UTERINE FIBROID BY HYPODERMIC INJECTIONS OF ERGOTINE.—Dr. T. Parvin records (*American Practitioner*, May, 1874), three cases of uterine fibroid, in which marked benefit followed the hypodermic administration of ergotine. In all the cases heretofore treated, so far as Dr. Parvin knows, the ergotine has been administered with glycerine, which Dr. J. T. Bowls, of Knightstown, Indiana, shows to be a needless and may be injurious addition, causing in some cases painful inflammation and threatening abscesses, which was not observed when the glycerine was omitted, and the efficiency of the injection was not found to be lessened.

Dr. A. Reeves Jackson reported to the Chicago Society of Physicians and Surgeons (*Chicago Med. Journ.*, June, 1874) five cases of fibrous tumour of the uterus treated by the method of Hildebrandt, and in three of them with decidedly favourable results. Dr. Jackson obtained the best results from a solution prepared according to the following form. Fifty grains of the extract (Squibb's) are dissolved in 250 minims of water, the solution filtered and made up to 300 minims, by passing water through the filter to wash it and the residue upon it. It represents ergot grain for minim, free from alcohol or other irritating substance. Latterly he has used this solution exclusively, and thus far has seen no irritation, pain, or inflammation result from it. He no longer selects the abdomen as the site for injection. Although some parts of the abdominal wall—as about the umbilicus, for example—may be less sensitive to puncture than others, yet all parts of it are more sensitive than the deltoid region; and inasmuch as the latter is more convenient, and the injections placed there equally efficacious, he now habitually selects the arm in preference to any other part of the body.

Another case was reported to the society by Dr. J. H. Etheridge, three by Dr. H. P. Merriman, and one by Dr. S. Fisher, in all of which beneficial results followed the hypodermic use of ergotine.

BLACK ON BROMIDE OF AMMONIUM IN CATAMENIAL EXCESSES.—Dr. J. K. Black, of Newark, Ohio, has often tested the efficiency of this preparation in non-structural excesses, and he speaks (*Cincinnati Lancet and Observer*, May, 1874) with confidence of its valuable powers. He says he no

more certainly anticipates the arrest of an attack of ague by the administration of quinia, than does he anticipate the control of the forms of catamenial excess referred to, by the proper administration of the bromide of ammonium.

In the administration of the remedy an essential rule is, that its use shall precede the expected period by at least ten days. Its administration only during the crisis will do very little, if any, good. The sedative influence of the remedy must precede and accompany the stage of ovarian and uterine vascular engorgement, which itself precedes the flow by several days.

Some writers have spoken quite favourably of the remedy in dysmenorrhœa and menorrhagia, administered in the usual manner; that is, during the crisis only. Having been frequently called to see cases of these disorders during their progress, he has failed to observe any very satisfactory evidence of its controlling power while administered only during the emergency. But when administered according to the above directions, it has not only, almost without exception, lessened a regular monthly excess, but it has, in appropriate cases, in quite a number of instances which he can recall to memory, changed a two-week into a four-week crisis.

Any associated disorder, which has even a remote bearing upon the menstrual excess, should receive appropriate attention; otherwise the controlling power of the bromide may be more or less uncertain or transitory.

MISCELLANY.

OPHTHALMIA IN PAUPER SCHOOLS.—Mr. Edward Nettleship has been appointed a temporary Inspector of the Local Government Board, to report on the causes and means of removal of the prevalent ophthalmia in poor law schools.

NAVAL MEDICAL SERVICE.—The following is a list of the Naval Medical Candidates who were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School at Netley, and who will receive commissions as surgeons in the Royal Navy, August, 1874:—

| | No. of Marks. |
|---------------------------------|---------------|
| 1. Saunders, E. H. | 4,297 |
| 2. Richardson, H. A. W. | 3,825 |
| 3. Collot, J. A. | 3,460 |
| 4. Luther, E. W. | 3,437 |
| 5. Benthams, R. | 3,425 |
| 6. Ross, N. C. | 3,394 |
| 7. Collins, H. B. | 3,179 |
| 8. Bennett, W. E. | 3,150 |
| 9. McKinlay, A. | 3,032 |
| 10. Hawton, S. W. H. | 2,910 |
| 11. Mulock, E. R. | 2,800 |

DEATH UNDER THE INFLUENCE OF CHLOROFORM.—An inquest was held on Saturday Aug. 1, at the Woolwich Union Workhouse, before Mr. Carttar, coroner, on the body of Ellen Graham, a single young woman, who died from the effects of the administration of chloroform by the house-surgeon. It appeared that the deceased was in service at Brighton; and one day, whilst she was cleaning the floor, a broken pin, which was in the house-flannel, ran into the back of her hand. The pain incapacitated her from service, and she returned home to Woolwich, and was advised to go into the Union Infirmary. After being there a few days Dr. Lloyd (the resident surgeon) incised the part with the object of extracting the broken pin, but, as she was unable to bear the pain, he desisted. On July 30

she expressed a wish to the doctor to have the pin extracted under the influence of chloroform. Dr. Lloyd said to her, 'There is no occasion for chloroform. You bore it before like a Briton, and can bear it again.' But she persisted in her wish for chloroform. He felt her pulse, and, considering her a fit subject for chloroform, administered it in the presence of two female nurses, named Nott and Bell. The chloroform took effect very quickly, the pin was extracted by forceps in about a minute; but deceased grew paler and paler, and was evidently dying. Dr. Lloyd at once sent for another medical man and used every means of restoration; but she expired within ten minutes of inhaling the vapour, the galvanic battery being applied for twenty minutes, but in vain. Dr. Lloyd had administered chloroform before in about 500 cases. The *post mortem* examination was made by Dr. Bullen, the house surgeon at Lambeth Union Workhouse, Dr. Wise, the medical practitioner called in when deceased was dying, and Dr. Lloyd. The heart was found flabby, and inclined to fatty degeneration, death having resulted from paralysis of the heart, induced by the effect of the chloroform. The jury returned a verdict of 'Died from the effects of chloroform administered during an operation,' and appended a rider that in future it would be desirable that a second medical practitioner should be present whenever chloroform was administered to inmates of the infirmary.

VALUABLE RESULTS OF DRAINAGE.—Mr. James Burdett Moxon, the Medical Officer of Health of the Glanford Brigg Union, makes some interesting remarks on the valuable effect of the improvements of the drainage of the district, which have been and are still being carried out to a very considerable extent.

'By these and other means the district has been improved in the most remarkable manner. It is probable, indeed, that in no part of the kingdom have general and subsoil drainage, and other agricultural improvements, made a greater change in the aspect and fertility of the country, and, incidentally, in the health of the inhabitants. A hundred years ago, perhaps, the Wolds and Cliff lands were uninclosed wastes or rabbit-warrens; even in the neighbourhood of the villages the country was open, and used for pasturage only; there were many uncultivated moors; the Ancholme Level was frequently submerged, and nearly useless for farming purposes; and the roads were of the most primitive nature, and almost impassable in winter.

'What was the effect of this condition of the country on the sickness and mortality of the inhabitants cannot now be stated with accuracy. It is, however, well known that fever and ague were permanently present; and there is no doubt that other diseases, such as rheumatism and consumption, would be more frequently seen than they are, even at the present day. Within my own memory there was an enormous consumption of quinine in this part of Lincolnshire, as a remedy for the ever-prevalent ague. It is probable, too, that the habit of opium-eating, which prevails so extensively in Lincolnshire, is connected, in its origin, with a desire to alleviate the distressing sensations of constant ill-health which most experience who live in malarious districts. Mr. Moxon believes, however, this pernicious habit is on the decrease. Among other causes of improvement, a recent Act of Parliament, which prohibits the sale of opium and certain other poisons, except by duly qualified and registered druggists, has banished it from the small village shops, and thus removed many of the opportunities for its ready purchase.

'With especial reference to ague, we observe, in passing, that we have here a notable instance of the effect of sanitary measures in the removal of the *causes* of disease. Good general drainage of this district, and other measures necessary for agricultural success, have, incidentally, abolished this disease. Let us hope that the operation of sanitary laws directed to the removal of the causes of other equally preventable diseases, will be equally successful.'

UNIVERSITY OF LONDON.—The following gentlemen have lately passed the Preliminary Scientific (M.B.) Examination for 1874:—*First Division*—Baddeley, Charles Edward, King's College; Berry, Frederick Haycraft, Guy's Hospital; Bond, James William, University College; Boulting, William; University College; Buck, John William, private study; Burry, Henry Burry Pullen, London Hospital; Bush, Erasmus, St. Bartholomew's Hospital; Castle, Hutton, St. Thomas's Hospital; Cattle, Charles Henry, Leeds School of Medicine; Cox, Frederick Augustus, private study; Crow, John Kent, Owens College; Drysdale, Alfred Edgar, University College; Franklin, Arthur, St. Bartholomew's Hospital; Giles, Bernard Faraday, Guy's Hospital; Gill, Richard, Royal Institution School, Liverpool; Granger, Edgar Bridden, Guy's Hospital; Gotch, Francis, B.A., University College; Hill, Alexander, University College; Jackson, Edwin, B.A., Owens College Medical School; Keep, Charles Henry, Guy's Hospital; Lyddon, Richard, St. Bartholomew's Hospital; McAlister, Donald, St. John's College, Cambridge; Mackern, George, Guy's Hospital; Manby, Herbert Lynsey, Guy's Hospital; Maylard, Alfred Ernest, Guy's Hospital; Munro, John May Herbert, College of Science, Dublin; Oldroyd, Joseph Hollinshead, University College and private study; Paddle, James Isaac, B.A., Royal College, Mauritius; Parry, Robert, Owens College; Pollard, Bilton, Epsom College; Prowse, Arthur Bancks, Liverpool School of Medicine, and private study; Robertson, David, LL.B., private study; Sedgfield, Arthur Robert Wyatt, King's College; Shaw, John, St. Thomas's Hospital; Smith, George, Royal School of Mines; Smith, Kenneth Rawlings, University College; Tilly, Alfred, St. Mary's Hospital; Tuke, William Samuel, private study; Uthoff, John Caldwell, Guy's Hospital; Wainwright, Robert Spencer, Guy's Hospital; Ward, John Hansford, Crescent School, Margate; Waugh, Henry Dunn, B.A., University College; West, Edward de Lancy, private study; White, Augustus Henry Scott, B.A., University College; Whitney, Neville Scott, University College; Wiglesworth, Joseph, Liverpool School of Medicine; Wilkinson, Arthur Thomas, B.A.; Owens College Medical School; Williams, David James, University College; Williams, Dawson, University College. *Second Division*—Andrews, William Stratford, University College; Brook, Lancelot, St. Bartholomew's Hospital; Buckell, Arthur Edward, University College; Burt, Alfred, Guy's Hospital; Clark, James Richardson Andrew, University College; Collins, William Edward, St. George's Hospital; Culhane, Fredk. William Slater, University and Epsom Colleges; Davies, William Edward, University College; Davy, David Henry, London Hospital; Dunbar, James John McWhirter, St. George's Hospital; Duncan, Henry Montague, University College; Dymott, Donald Frederick, Hartley Institution; Gabb, James Percy Alwyne, University College; Green, Thomas Beaufoy, University College; Haddon, Walter Baugh, Liverpool School of Medicine and private study; Heath, William Lenton, St. Bartholomew's Hospital; Hill, Charles Birnie, University College; Hodge, Arthur, University College; Hopkins, John, University College; Jackman, William Thomas, St. Bartholomew's Hospital; Jackson, Alfred Henrick, Owens College; Jackson, Arthur, St. Bartholomew's Hospital; Johnstone, William, University College; Jones, Arthur Lloyd, University College; Jones, Roger Hughes, Liverpool School of Medicine; Juler, Henry Edward, St. Mary's Hospital; Landon, Edward, St. Thomas's Hospital; Lendon, Alfred Austin, University College; Lubbock, Montagu, Guy's Hospital; Marsh, Joseph Henry, St. Thomas's Hospital; Matthews, A. thur, Sidney Sussex College, Cambridge; Matthews, Valentine, King's College; Parkyn, Ernest Albert, University College and private study; Payne, Charles Alexander, private tuition; Plunbe, Samuel Thomson, St. Bartholomew's Hospital; Rendell, James Robson, Owens College; Roberts, David Davies, Guy's Hospital;

Roeckel, Waldemar Joseph, St. Bartholomew's Hospital; Shaw, George, private study; Smith, Herbert Urnson, St. Thomas's Hospital; Sutcliffe, John, Owens College Medical School; Tebbitt, Frederic, St. Thomas's Hospital; White, Charles Haydon, St. Thomas's Hospital.—The following have passed the First (M.B.) examination: Entire Examination:—*First Division*—Burton, Samuel Herbert, University College; Carrington, Robert Edmund, Guy's Hospital; Keetley, Charles Robert Bell, St. Bartholomew's Hospital; Tirard, Nestor Isidore Charles, King's College. *Second Division*—Blake, Henry, St. George's Hospital; Fox, Thomas Colcott, University College; Freund, Percy Herbert Edmund, St. Thomas's Hospital; Giles, George Michael James, St. Mary's Hospital; Godfrey, Charles Walter, University College; Gosling, Charles Edward, Queen's College, Birmingham, and St. Bartholomew's; Hunt, Joseph William, University College; Joule, John Samuel, Anderson's University and St. Bartholomew's; Kidd, Walter Aubrey, Guy's Hospital; Pinnell, Thomas Mark, University College; Rosister, George Frederick, St. Thomas's Hospital; Sankey, Herbert Richard Octavius, University College; Snell, Edward Arthur, King's College; Symonds, Charters James, Guy's Hospital; Trafford, John Foster, University College. Excluding Physiology: *First Division*—Champneys, Henry Laurence, Guy's Hospital. *Second Division*—Baker, Albert De Winter, Guy's Hospital; Bigger, Samuel Ferguson, Liverpool School of Medicine; Cross, Francis Richardson, King's College; Cuming, Charles Henry, University College; Finch, Alfred, Guy's Hospital; Pickup, William James, University College; Ryley, James, University College. Physiology only: *First Division*—Whitelegge, Benjamin Arthur, University College. *Second Division*—Batterbury, Richard Legg, King's College; Cooke, Edward Marriot, King's College; Duke, Herbert, Guy's Hospital; Evans, Charles Walter, University College; Ferrier, John Christian, Guy's Hospital; Harrison, Charles Edward, St. Bartholomew's Hospital; Landon, Arthur Jermyn, St. Bartholomew's Hospital; Langley, John Geoffrey, University College; Taunton, William Whitchurch, B.Sc., University College.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, AUGUST 19, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

REUMONT ON METALLIC POISONING AND ITS TREATMENT BY MINERAL WATERS.

There are two kinds of quicksilver disease: that of artisans, which is produced in the practice of various arts in which mercury is employed; and medicinal mercurialism, which is produced by mercury introduced into the system for medicinal ends. Both sorts are in their nature very similar, and differ chiefly in the degree of acuteness of their symptoms, and according to the presence or absence of combinations with affections of the system previously existing—especially syphilis.

We need not inquire here whether mercury applied in the way of inunction reaches the system only by the inhaling and the swallowing of the volatile portions of mercury, or by actual penetration through the skin. The fact is sufficient for us, that mercury in various forms and in different ways enters the body, and through the blood reaches its most different organs. This is proved partly by its effects, and partly by the presence of the metal in the blood, in various organs, and in the secretions and excretions. Riederer found in the excretions and excrements of a dog who had in the course of thirty-one days received 2,789 grammes of mercury, nearly ninety-four per cent. of the mercury that had been introduced. After the fæces and the urine, he found most in the liver, next most in the brain, the heart and the lungs, the spleen, the pancreas, the kidneys, the testicles, and least in the muscular substance. In this last respect Heubel's experiments with lead give the same results.

According to the theory of Voit, all the preparations of mercury are, with the help of the chloride of sodium (in the perspiration and in the blood-serum), of the blood-corpuscles and of the albumen, transformed into corrosive sublimate, which in the blood enters into a double combination of albuminate of oxide of mercury with chloride of sodium, the form in which all preparations of mercury exist in the system. This theory arrived at after most careful research continues to be serviceable, and is used to explain the disease and the health-producing effects of the metal. Although the later researches of Boeck seem to show that mercury has no effect on the albumen of the circulating fluid, it does not follow necessarily that it has not an action on the more fixed albumen of the organs, on which the symptoms of hydrargyrosis are dependent.

Of the alteration produced in the blood by mercury we know little, and that little is contradictory. Overbeck's careful researches lead him to believe that mercurialism produces a sort of anæmia, that in mercurial blood the quantity of blood-corpuscles and of albumen is diminished, while its coagulability is increased, and its amount of water is fluctuating.

It seems to be established that all preparations of mercury, if introduced into the system in sufficient quantity, induce an increased excretion of bile, and sometimes a passage of albumen through the urine.

As to the form in which mercury quits the system, little is known with accuracy. In the alimentary canal, it is found as sulphuret of mercury. It is not determined in what shape it appears in the perspiration. As to the stories of metallic mercury being given out in baths, they require no serious consideration; although it is certain that gold and silver articles worn by those who are taking mercury, occasionally become stained by an amalgam. It has been concluded that mercury in the urine is in the shape of an albuminate, chiefly because the urine of patients under mercury often contains albumen. On the whole the view of Overbeck is probable, that mercury is not eliminated from the system, until it has been separated from its albumen.

The question how long mercury remains in the system, is one of practical importance. The anti-mercurialists speak in support of their favourite views, of its remaining many years in it; but there is no proof of this. According to Overbeck and Waller, the spontaneous elimination of mercury proceeds slowly, and may occupy seven months, or even longer. Kussmaul speaks of many months, up to twelve, and even more. The organs which appear to retain the mercury, the longest are the liver and the kidneys, and the liver contains most.

Kussmaul and Overbeck have done the great service, by their researches, of dispelling in a great measure the mistaken views which have prevailed among physicians, respecting the relation of syphilis to mercury. 'A two-fold picture of mercurialism,' says Kussmaul, 'runs through our literature; one painted by those who have studied it as it occurs among quicksilver workmen, the other by those who study syphilis. The first picture has altered little in the course of time; the second has always varied according to the course of opinions on syphilis. A set of fanatical antimercurelists put down every ailment in the whole course of the life of a man, who may have once taken a few grains of mercury for syphilis, to the account of the metal; and looked on syphilis as a very mild disease, unless aggravated by the use of mercury. The most violent even denied that there was such a thing as syphilis, regarding it only as mercurialism.'

In its best-marked and really frightful form, true mercurial disease is rarely witnessed except in quicksilver workmen; it shows itself in a much milder form in those who have used mercury only for medicinal purposes. In the mercurialism of artisans there are three stages of development—the stage of erethism, that of tremor, and the final stage, although there is no marked line of distinction between them. In all stages, the nervous system is affected in a marked degree. Such marked stages are seldom or never to be seen in mercurialism from the administration of the metal, and the symptoms are seldom simple; they are almost always combined with those of syphilis or of some other disease.

The pure symptoms of mercurialism occurring after the medicinal use of the metal that occur most frequently, are either general or local: anæmic and chlorotic conditions, disturbance of nutrition showing itself chiefly in emaciation and in muscular weakness; gastric and febrile conditions, affections of the nervous system, such as painful sensations, gnawing rheumatic pains, tremors, and paralysis;

and consequent on these, swimming in the head, loss of memory, &c. But these last symptoms undoubtedly belong more or less to syphilis also. The commonest local symptoms are shown in the mucous membrane of the mouth, the tonsils, the salivary glands, and in fresher cases, in the mercurial rashes.

In both mercurial and syphilitic affections there is a certain alteration in the blood; but it must vary in the two, as the symptoms to which it gives rise are very different. In syphilis, one of the first symptoms is the swelling of many of the lymphatic glands, whereas we have only rarely in mercurialism some swelling of the cervical glands, as a consequence of stomatitis. The pathological productions of the two diseases are very different. The mercurial dyscrasy must be viewed, on the whole, as a catalytic process, which has little to do with new or plastic formations, and which, at most, causes some thickening of the mucous membranes and the enlargement of a few glands; while syphilis shows the greatest tendency to hyperplastic and new formations. Soft nodes (gummy exudations) occur in syphilis only.

As regards the further question, whether mercurialism does not impart a malignant character to syphilis, we may reply, that the worst forms of syphilis occur in those who are not treated at all, or certainly not with mercurials; while we grant that the solvent action of mercury may be prejudicial in phagedænic and sloughing ulcerations. As to the affections of the bones ascribed to mercurialism, we have already said, that only local ones of the jaws, connected with profuse salivation, are ever produced.

If lead be introduced into the system for any length of time, in small quantities, the characteristic symptoms of lead-poisoning are produced. Lead is partly inhaled in extremely minute particles, partly taken up in the intestinal canal, partly introduced through the skin, or through the nasal passages in snuffing into the circulation. It is probable that all preparations of lead become converted in the intestinal canal into albuminates, which, being dissolved in the stomach, are partly introduced into the system. It is not known in what form it exists in the blood, but it occurs in it in smaller quantities than in other parts of the system. From the blood, the lead passes into the parenchyma of various organs.

Little is known of the mode of operation of lead in the system, though it has been generally believed that it has a special affinity for the voluntary muscles, and occasions paralysis of them and loss of their electro-muscular contractibility. But Heubel has recently arrived at some important conclusions. He finds that the relatively greater quantity of lead accumulates first in the osseous substance, and next in the kidneys. After this come the liver, the central portion of the nervous system, and only after these the muscular and intestinal fibres. Heubel, therefore, rejects the theory that blood impregnated with lead has a power of contracting the muscular coats of arteries and of veins. Heubel, regarding the liver and kidneys as being merely the organs that eliminate lead, and on that account contain a large portion of it, thinks that lead has on the whole the greatest affinity to the nerve-substance.

The elimination of lead from the system, apart from what passes through the intestinal canal as sulphuret, takes place most frequently through the biliary secretion. It has been assumed that lead is eliminated through the skin, owing to the dark colour

of the skin after sulphur-baths which has occasionally been observed. The occurrence is undoubtedly very rare, and is explained by the action of the sulphur of the water on particles of lead lying in the folds of the skin.

Lead-poisoning has of late years become more frequent, owing to the use of cosmetics and of snuff containing the metal. It sometimes requires much discrimination on the part of the physician to discover it. The blue line on the gums is often a most valuable sign. The peculiar symptoms of Saturnism are, according to their frequency, lead colic, pains of the joints, paralysis, affections of the brain, anæsthesia. The characteristic paralysis attacks most frequently the fingers, the hands, and the fore-arms, less often, the lower extremities. The great characteristic is the loss of extensor, not of flexor, power.

As to other metallic poisonings—chronic arsenical poisoning is rare. Some doubt whether there is such a thing as chronic copper poisoning, but paralysis of the extremities is said to characterise it.

It would be very desirable to explain how sulphur-waters are able to fulfil the indication of disengaging the metal stagnating in the system, and of causing its quicker elimination through the skin, liver, and kidneys. To account for it, Astruc has propounded the theory with reference to mercury and to lead, that the sulphurets of the alkalies and the sulphate salts render the metallic albuminates soluble, and that the albuminates, having been made soluble, are conveyed out by means of the secreting organs, whose functions have been heightened by the whole process of a water-cure. Probably the sulphur-waters act in this case by dissolving the protein-compounds. For the present we must be satisfied to use such chemical views as working hypotheses, and indeed they are supported to a considerable extent by clinical observation, although there is no doubt that there are other factors concerned in the elimination of metals.

We know as yet few facts which prove direct elimination of metals by the use of sulphur-waters. The occasional occurrence of mercurial stomatitis and salivation during a sulphur-water cure in patients, who have used mercury even at a considerable distance of time, can only be explained by the blood's taking up metal which had been combined with the tissue of organs. There are analogous cases of the reappearance of symptoms of lead-poisoning in patients, who had been apparently cured of it. Although we can receive only with the greatest reserve old and new stories of metallic quicksilver being found in the baths used by mercurialised patients, or in their cutaneous eruptions during a bath-cure, yet it would seem that the metal is sometimes eliminated through the skin. Besides the case quoted by Overbeck, two cases have occurred to me (Reumont) and to my colleague Diemer, which can scarcely be interpreted in any other way than as instances of elimination of mercury in the form of sulphuret in the perspiration. I have in strongly mercurialised patients, observed by the electrolytic process during the cure at Aix, mercury in very minute quantities in the urine. Hemmann, of Schinznach, has made the statement that he has washed metallic mercury from the faces.

Like mercury, all other metals must, under treatment which relieves the symptoms, be extracted from the tissues. And when Tanquerel speaks of a black appearance of the skin in cases of lead-poisoning treated with sulphur-baths, he attributes this, as has been already remarked, to the union of sulphur with minute portions of mercury in the folds of the

skin. I have (says Reumont) several times observed somewhat similar effects in those treated with mercurial inunction and sulphur-baths.

But much more important for the physician than the theory of their operation is the clinical observation of the value of sulphur-waters in metallic poisonings. The mercurialism of artisans naturally is seldom sent for treatment to baths, whereas medicinal mercurialism is very common, and very frequently complicated with syphilis. Some of the most renowned practitioners bear testimony to the value of sulphur-waters in such cases. Robbi commences his cure with sulphur-baths, Himby recommends them in mercurial amaurosis, Horn and Romberg in tremor, Roth in mercurial hoarseness. Many French, Swiss, and German physicians, besides those of Aix-la-Chapelle, are equally loud in their praise.

As to the method of using sulphur-waters in such cases, it is necessary to introduce the sulphur into the blood in every variety of way. Baths, drinking, and inhalations all come into play, and douches or vapour-baths, are of special use in helping the elimination of the metallic molecules.

Chronic lead-poisoning has of late years been pretty frequently treated at sulphur-baths; it has generally been caused by food or drink containing lead, by cosmetics, or by snuff. Men of great clinical repute as Schönlein, Romberg, Autenrieth, and many others, have had the greatest faith in its treatment by sulphur-waters. I myself have cured by them various cases of paralysis and colic induced by snuff.

There are very few notices of the treatment of arsenical or copper poisoning by sulphur-waters. But there are a few successful cases on record. I myself treated with success a case of arsenical poisoning brought on by stuffing animals with arsenical paste.

[This paper forms a natural supplement to Dr. Reumont's former one on 'Constitutional Syphilis,' which lately appeared in the LONDON MEDICAL RECORD. It is also a condensed translation of a portion of his article in *Valentiner's Handbuch der Balneologie*. Dr. Reumont has published the portion of that article which referred to syphilis and mercurial poisoning in a separate shape, and has added some very sensible remarks on syphilidophobia, a troublesome form of hypochondriasis.—*Rep.*]

J. MACPHERSON, M.D.

BERGER ON HEMICRANIA.

Dr. Oscar Berger publishes in Virchow's *Archiv*, vol. lix. parts 3 and 4, an exhaustive paper of twenty-five pages, on the pathogeny of hemicrania, giving the histories of several cases, with clinical remarks upon them. The author prefaces his paper with a review of the opinions of different observers. He first instances the view put forward by Du Bois-Reymond, that the paroxysms of pain depend upon a tetanus of the muscular coats of the vessels of the affected side, or tetanus in the sympathetic region of the corresponding side. Pressure exerted by contraction on the sensory nerves may be the immediate cause of pain, just as in parturition or colic. The vomiting and glimmering of the eye in migraine, Du Bois-Reymond thinks, may be explained by the fluctuation in the cerebral circulation, as in Wollaston's theory of seasickness.

Eulenburg and Guttmann observed, in several

cases presenting the same characters, a contraction of the pupil towards the end of the attack, and simultaneously with reddening and rise of temperature of the affected side.

Brunner observed, in his own case, a distinct painfulness on pressure in the neighbourhood of the upper and middle cervical ganglia of the sympathetic.

Du Bois-Reymond's hemicrania sympathico-tonica is not a true neuralgia, but an affection of the sympathetic of the neck.

Berger has noticed several cases of hemicrania, presenting symptoms which supported Du Bois-Reymond's view completely, and for which nitrite of amyl was ordered; later, Vogel and Holst have employed the same remedy with good results.

The author has observed dilatation of the pupil in two only out of the six cases; and in no case was he able to prove a secondary contraction.

About eight years after Du Bois-Reymond's communication, Möllendorff started a theory of hemicrania, according to which it is due to a want of tone of the vaso-motor nerve controlling the carotid artery, whereby the vessel relaxes and an arterial flow towards the cerebrum takes place; i.e. an arterial hyperæmia in the neighbourhood of the cervical sympathetic. In opposition to Du Bois-Reymond's view, he advanced in support of his opinion the following circumstances. Compression of the carotid of the affected side caused instant cessation of headache, which returned within the first pulse-wave after slackening the pressure; whilst, on the other hand, compression of the carotid of the sound side increased the headache; dilatation of the arteria centralis retinae, and congestion of the choroidal vessels of the affected side pointed to the same conclusion. Möllendorff observed likewise a marked retardation of the heart's action, and a small contracted radial pulse, with a soft large wave in the carotid. These facts, says Berger, may explain the subjective sensations of coldness of the extremities with heat of the affected part. Berger thinks, therefore, that besides a hemicrania sympathico-tonica, a hemicrania sympathico-paralytica must be admitted, in which, instead of cramp of the muscular coat, there is a want of tonicity.

The retardation of the circulation mentioned by Möllendorff is, according to the observations of Landois, dependent upon a direct irritation of the medulla oblongata and vagus nerve. The increased secretion of saliva and urine accompanying migraine is explained by Möllendorff, as dependent upon congestion of the organs brought on by secondary dilatation of the vessels.

In cases of hemicrania sympathico-paralytica we must look, says the author, for another cause of the pain than that asserted by Du-Bois Reymond. It is dependent in great measure upon the hyperæmia itself; the distended state of the blood-vessels exerts pressure on the nerve-fibres and ganglia of the brain. The author agrees with Eulenburg and Guttmann in thinking that the pain in the tonic cases may be explained by the fluctuating character of the arterial current. The local anomalies of the circulation are to be regarded as the essential causes of the symptoms in migraine.

Berger quotes the old authors, viz., Fordyce, Monro, Tissot, Ackermann, and Frank, and then proceeds to give at great length the clinical history of a case of right hemicrania sympathico-paralytica. He remarks that there was no hereditary tendency to ner-

vous disease, but there were symptoms of scrofula at the age of fourteen. The woman had suffered from headaches since her eighteenth year; they used to occur after any bodily or mental fatigue, and at the menstrual periods. The author goes on to give in minute detail an account of the symptoms of true megrim exhibited by the patient. An attack appears to have been brought on by such slight causes as draughts of air, close atmosphere, exposure to the direct rays of the sun, etc. The reddening of the right side of the face was limited exactly to the middle line in front. The temperature of the two sides of the face, as measured by equivalent thermometers, showed an increase of 5.5° to 7° Fahr. on the affected side. The right temporal artery was manifestly dilated, and in less degree the right carotid also. "The conjunctiva was congested. The fissure between the eyelids was narrowed and the pupil contracted; the reaction to the stimulus of light was impaired. However, the ophthalmoscope showed no difference in the functions of the two eyes, or in the power of accommodation. (It is to be noted that the other symptoms were not so pronounced at the time of examination.) An extremely intense pain occurred on pressure over a spot corresponding to the upper cervical ganglion of the sympathetic. Pressure also over the spinous processes of the seventh cervical and first dorsal vertebræ gave great pain at all times, but especially during an attack.

There would seem, the author thinks, no doubt that the symptoms presented by the case are to be referred to the cervical sympathetic of the right side. He regards the pain produced by pressure directed over this nerve as an important and nosologically interesting symptom. Of little less interest appears a condition of heightened cutaneous sensibility of the right side of the face during an attack, and accompanying the hyperæmia. Not only was ordinary sensation increased, but the special sense of touch also.

The patient, whose malady had remained unchanged for ten years, was subjected by Dr. Berger to a course of treatment by electricity over the right sympathetic, the cathode being planted at the inner border of the auriculo-mastoid fossa, while the anode was placed over the first dorsal vertebra, during each sitting, which lasted a few minutes. The current was alternately opened and closed.

The result of this treatment was as surprising as interesting. After the first six or eight sittings, the attacks became much less severe; especially had the true violent character of the megrim disappeared. Four months after the commencement of this treatment, even at the menstrual periods, when she used invariably to have a violent attack, she escaped with only one. The reddening of the right side of the face returned now and then, but was confined to the forehead. The oculo-papillary symptoms were alone distinctly present. The vaso-motor nerves of the skin of this patient were so susceptible of impressions, that the applications of the poles of the battery for three or four minutes sufficed to cause erythema.

The symptoms of this case, the author considers, bear an interesting relation to some undoubted results of experimental inquiry; corresponding as they do, in all particulars, with those following section of the cervical sympathetic. The reddening and elevation of temperature of the right side, with excessive sweating and lacrymation, depend upon paralysis of vaso-motor fibres, and consequent widening of the blood-vessels. The contraction of the pupil and narrowing of the orbicular aperture are

due to paralysis of the oculo-papillary fibres, as the researches of Bernard, and later of Du Petit and Biffi, have taught us. The lowering of the pulse is to be referred to the action of the dilated intracranial vessels, in causing an irritating pressure upon the nerve-centre supplying the heart.

The author next proceeds to quote examples of similar symptoms caused by compression of the nerves from traumatic lesions or other causes; 1st, Cases of paralytic myosis, observed as arising from swelling of the glands of the neck (Willebrandt) or from aneurism of the aorta and its great branches (Gairdner, Coats); 2nd, A case related by Ogle, in which, after healing of an abscess in the neck, frontal headache, as well as vaso-motor and oculo-papillary symptoms, supervened; also a case of gun-shot injury to the sympathetic, related by Mitchell, Morehouse, and Keen.

Holst sought to introduce a galvano-therapeutic treatment, after observing its effects upon the several varieties of megrim, in a methodical manner. In hemicrania sympathico-tonica, he recommended the anode to be placed on the sympathetic nerve, the cathode at the handplate, and after two or three minutes the current to be gradually shut off; on the other hand, in the paralytic form, he recommended the cathode to be placed upon the nerve, and the current to be repeatedly opened and closed. The first method, he asserted, would cause a lowering of the irritability, and the latter a powerful stimulation of the nerve. For the above action of the anode, Dr. Berger thinks there is no physiological warrant; his own observations on the galvanic treatment in hemicrania sympathico-tonica have hitherto led to no certain results.

Eulenburg and Guttmann (in Germany) recommended, in the paralytic form, liquid extract of ergot, to cause contraction of the vessels through the vaso-motor centres; and this treatment has been tried with success by Woakes (in England). The otherwise unexplainable loose motions coming on at fixed hours, may be explained on the supposition of a paralysed state of the vaso-motor nerves of the alimentary canal.

The author finally gives the particulars of three other cases of hemicrania sympathico-paralytica. The chief interest of the first consists in the attacks having originated after exposure to a scorching sun. The pain in the head was followed by vomiting and purging, with abdominal pain. In relation with these phenomena, Berger mentions the opinions of physiological authors. For instance, according to Pincus and Adrian, section or extirpation of the abdominal sympathetic plexus causes disturbance of the circulation (hyperæmia and extravasation) and sometimes interference with nutrition (ulceration). According to Budge and Samuel, diarrhœa occurs after extirpation of the cœliac plexus; while, on the other hand, Pincus affirms that paralysis of the vaso-motor nerves produces rather a diminution than an increase of the intestinal secretion. Moreover, Brunner declares that the attack of megrim frequently ends with vomiting and diarrhœa, and concludes from this, that beyond the cervical sympathetic the solar plexus is likewise affected. The points of interest in the second case lie in the fact of both forms of megrim being present in the same individual, and the abundant salivation. The chief interest of the third case consists in the marked hereditary tendency to nervous disease.

J. B. BRADBURY, M.D. (Cambridge).

THE INTERNATIONAL SANITARY CONFERENCE IN VIENNA.*

(Concluded from page 495.)

III. *International Commission on Epidemic Diseases.*

With regard to the formation of an International Commission on Epidemic Diseases, the Conference recognised fully the value and necessity of such a commission, especially with regard to cholera. The following are the most important of the propositions on this subject agreed to by the Conference.

'An International Epidemic Commission should be organised. It should be permanent, and have its seat at Vienna. Its members should consist of delegates from all the Governments taking part in it, partly medical men and partly lay officials. A president should be chosen from among them as representative of the Commission, to correspond directly with the different Governments, and eventually with the various sanitary boards. The International Commission should be independent in its scientific labours, but administrative questions should be decided by a majority, every State having a vote in all final decisions. The ordinary routine of business should be settled by the Board itself. The Commission should be bound to communicate to their respective Governments the results of their scientific and administrative labours. The necessary computations of cost should be made by the Board and submitted to the respective Governments. The expenses should be covered by the contributions of the different States, and eventually by receipts. The sum total required should be apportioned among the different States with reference to the numbers of their population and the tonnage of their commercial fleet. The objects of the International Epidemic Commission should be the furtherance of the study of epidemics among mankind; proposals for the erection and administration of quarantine establishments; professional opinions in answer to inquiries from any Governments represented in the Commission, the arranging of international sanitary conferences as often as necessity requires, and the drawing up of their programmes. Where epidemics are constant, permanent stations should be established, and, where they exist only for the time being, temporary arrangements should be made for the study of the epidemic on the spot, and inquiry into means of protection from it. In the same manner, during any great epidemic, arrangements should be made to follow it from place to place, with the object of studying the laws of its dissemination. For those territories which have no organised sanitary service, such epidemic stations should be established with the consent of the Governments to which they belong on the principle proposed by the International Commission of assisting such countries in times of severe epidemics. The international epidemic stations should be subject to the Commission. Their *personnel* should be appointed by them with the consent of those States on whose territory their labours are carried on. The present arrangements to last for ten years. The revision of separate details on the motion of any of the States concerned, or by a vote of an international conference, to be reserved.'

The last subject which the Conference took into

consideration was yellow fever. As it had already declared that the International Commission on Epidemic Diseases should not concern itself merely with cholera, but also extend its attention to other epidemic diseases which are spread by human intercourse, it merely remained to express the opinion that the same regulations (inspection or quarantine) should be adopted by individual States in regard to yellow fever as in regard to cholera. For the promotion of the study of the etiology of yellow fever, the Commission recommended a continued and sufficient investigation of the outbreak and spread of the disease on board ships coming from places infected with yellow fever. These researches should be carried on in the same way as with cholera.

The concluding meeting of the Conference was held on August 1. The President gave a summary of the labours of the Conference, after which the conclusions arrived at were signed by all the members. Baron von Orczy, of the Austrian Foreign Office, then addressed the members of the Conference as follows.

'Allow me, gentlemen, to make myself the interpreter of the sincere regret which His Excellency the Minister for Foreign Affairs feels in not being able personally to thank the Sanitary Conference for the enlightened and unceasing zeal which it has manifested during its labours. Commissioned by him to be his representative here, I esteem myself fortunate in being able to discharge a pleasant duty, when I express, in the name of His Majesty the Emperor and King, my illustrious master, the complete satisfaction which his Government has felt at the results of your deliberations. Indeed, His Majesty's Government can only wish success to the work of the Conference, as it is not only in itself the first step to a general undertaking, but at the same time may be regarded as the foundation of future diplomatic transactions. The hope appears to be well founded that these transactions, resulting as they will from the final conclusions of two separate sanitary conventions, will secure a true practical value to your labours. One of these conventions has aimed at the establishment of a greater uniformity in fundamental regulations and prophylactic measures—at least between the two groups of States which will hereupon adopt the same system of protection against cholera. The other gives the imperial and royal Government reason to hope to be able to see in the early future the realisation of the idea of a permanent international sanitary commission, of which you have given the first outline, and which will have to be as a connecting link between the learned and the official sanitary organs of the various countries of the civilised world. As the Government of his majesty the Emperor and King intends to communicate by circular letter with all the Governments represented in this Conference, and to utilise, for the obtaining of clear and precise stipulations, the landmarks erected by your endeavours, the Government will be greatly obliged to you, gentlemen, if each of you in your respective Governments will afford your practical support to the work to which you have devoted your judgment. You are in a better position than any one else to forward an affair which has indeed become your own. Allow me to give you the assurance that, should you be inclined to afford me your enlightened attention and care as hitherto to the great questions of humanity which you have taken in hand, you may at any time count on the active support of my Government. I have had the

* From the *Allgemeine Medicinische Central-Zeitung*.

pleasing duty of offering you an expression of most lively gratitude; I now renew the expression, and declare the session of the second international sanitary conference closed, and I beg you at the same time, at the moment when each of you returns to his home, to accept my best wishes.'

Dr. Fauvel then expressed the thanks of the Conference to the president, Baron von Gager; and Dr. Lenz thanked the Austro-Hungarian Government. Baron von Gager having briefly replied, the session of the Conference came to an end, its meetings having extended over the whole month of July.

ANATOMY AND PHYSIOLOGY.

GREVE ON THE ACT OF VOMITING.—Carl Greve (*Berliner Klinische Wochenschrift*, July, 1874), says that, although the experiments of several physiologists, and especially those of Magendie, seem to prove that the stomach is entirely passive during vomiting, and that the expulsion of its contents does not depend in the least on the contraction of its walls, yet numerous others still assign to it a more or less active rôle. The existence of a nervous centre for the act of vomiting, its situation and the nervous communications connected with it, being all more or less uncertain, Greve undertook some experiments to settle the disputed question. He made use of apomorphia, which he finds to be the most certain and speedy of emetics, and accompanied by far fewer concomitant and subsequent effects than any other. Vomiting occurs after division of the vagi. The negative results obtained by Quehl in this respect were due to his having tied the dogs experimented on upon their backs, in which position they hardly ever vomit except when their stomachs are full. When dogs have emptied their stomachs in the morning by violent vomiting, they will not vomit in the afternoon when tied either upon their backs or bellies, but will do so at once if set free and an emetic administered. They vomit more easily when placed on their bellies than on their backs. After the injection of apomorphia apnoea cannot be produced; and, *vice versa*, when vigorous artificial respiration is kept up, it counteracts the emetic power of apomorphia. The centre for vomiting is identical with or close to the respiratory centre. The nervous path along which the irritation is propagated from the vomiting centre to the organs concerned in the act, lies in the spinal cord as far as the sixth dorsal vertebra. When the cord is divided below this point vomiting still occurs, but not when the point of section is above this vertebra. The stomach takes no part whatever in the act of vomiting.

T. LAUDER BRUNTON, M.D.

SCHUTZENBERGER ON COMBUSTION IN THE ANIMAL ORGANISM.—The researches of MM. Mathieu and Urbain establish clearly that fresh arterial blood, preserved at a temperature of 98°6' to 104° Fahr., consumes the oxygen united to the hæmoglobin with extreme slowness. Schutzenberger finds that oxygenised blood, preserved also at a temperature of 98°6' Fahr., loses its oxygen very slowly while the blood is fresh; but that, when putrefaction sets in, the loss is very rapid. This he considers to bear out the generally admitted principle that these combustions take place especially in the depth of the

tissues. These organic tissues act by their cells on the oxygen as do the cells of the yeast of beer. It is well known that the yeast of beer possesses the property of absorbing oxygen, with production of carbonic acid. Schutzenberger has investigated the absorbent power of yeast, and says that he has discovered some of the principal laws. Great similitude, from a chemical point of view, exists between the products elaborated by yeast and those formed in the tissues of the animal organism. This similitude led him to the idea of transforming arterial blood into black venous blood by analogous means, transformation quickly and successfully effected.

PAGET HIGGS, D.Sc.

BENEDIKT ON THE INNERVATION OF THE PLEXUS CHORIOIDES INFERIOR.—M. Benedikt (*Virchow's Archiv*, vol. lix.) describes, as existing in the inferior choroid plexus of man, nerve-twigs ending partly in the epithelium, partly in the vessels. These nerves arise from a nucleus lying in the medulla oblongata to the outer side of the olivary body, and connected with the so-called lower nucleus of the vagus nerve. The cells in this nucleus are partly sensory, partly vaso-motor; and Benedikt concludes, from the observations of Betz, that cells of the same kind exist elsewhere, and send processes to the vessels of the central nervous system.

DALTON ON THE SPECTRUM OF BILE.—Dr. J. C. Dalton recently read before the New York Academy of Medicine (*New York Medical Journal*, June, 1874) a paper in which he discussed, first, the spectrum presented by fresh bile, which depends on the presence of its normal colouring matters; and, secondly, the spectrum presented by the coloured fluid of Pettenkofer's test, which depends for its production on the presence of the biliary salts. He gives the results of a series of observations on the spectroscopic characters of a number of different specimens of bile as follows. 1. The spectrum of bile is characterised, as a general rule, by an absorption-band at C. 2. The existence and intensity of this band are proportional to the predominance of green in the colour of the bile. 3. The spectrum of bile is also distinguished by a diminution or absence of the orange and yellow, and a corresponding extension of the red and green. 4. There are sometimes also two other absorption-bands, comparatively uncertain and ill-defined, at D and at D 30 E. 5. The pure biliary salts in alcoholic solution, treated by Pettenkofer's test, give a spectrum with absorption-bands at E and F. 6. In a watery solution, treated by the same test, they give a spectrum with but one absorption-band, namely, at E.

BOWDITCH AND MINOT ON THE INFLUENCE OF ANÆSTHETICS ON THE VASO-MOTOR CENTRES.—In an interesting investigation on the influence of anæsthetics on the vaso-motor centres, Dr. H. P. Bowditch and Charles S. Minot deduce (*Boston Med. and Surg. Journal*, May 21, 1874) the following conclusion as possessing a high degree of probability.

'While ether and chloroform resemble each other in their effect on those nervous centres whose activity is connected with the conscious perception of pain, the latter acts much more strongly than the former upon those centres which regulate the arterial blood-tension, and thus affects profoundly the conditions of animal life. Ether and chloroform

are, therefore, both anæsthetics, but chloroform is also something more.'

ONIMUS ON GENERATION OF PROTO-ORGANISMS IN MEDIA FROM WHICH GERMS OF AIR ARE EXCLUDED.—M. Onimus describes in *Comptes Rendus* (July 20) his experiments on the changes undergone by albuminoid substances in the presence of air deprived of its germs. He says:—

Our process was that of introducing blood or the white of an egg directly into a vessel, to which air could only come through a thick layer of carded cotton or amianthus.

The apparatus we used consisted of a globe of glass closed with a caoutchouc stopper, through which passed three metallic tubes. Two of these tubes ended exteriorly in a stopcock for maintaining a vacuum, and a cylinder seven centimetres long, into which the cotton or amianthus was put. The third tube was also terminated by a stop-cock, with a trocar at the end of it, constructed so that one could prevent entrance of air throughout the length of the tube.

The mode of operating was this. We introduced into the glass globe about 300 to 350 grammes of water, two grammes of phosphate of ammonia, and 50 centigrammes of chloride of sodium. We close the vessel with its stopper, and boil the liquid half-an-hour at two different times. The steam escapes by the three tubes, the cocks of which are open; it chases out the air, and destroys by heat the germs which may be present. We close the cocks during ebullition, and let the apparatus cool. A vacuum is formed in the globe, and this vacuum remains complete as long as we wish; which shows that the exterior air cannot enter by any interstices which might, at the same time, allow the entrance of germs.

When the liquid is completely cooled we introduce the trocar, after heating it, into the vena cava or the heart of a rabbit, and open the cock of this tube. The blood is immediately sucked in by the vacuum in the globe, without coming into contact with air. When a few drops of blood have thus been received, the cock is closed.

To introduce white of egg (an experiment quicker and more easy), we have taken eggs that were quite fresh and intact. After washing the shell with sulphuric acid, we have covered it with collodion at the part where the trocar is inserted, so that there cannot enter the least bubble of air between the trocar and the egg-shell.

Lastly, to admit the air deprived of its germs, we open the cocks of the two other tubes; the air comes into the globe after traversing a thick layer of carded cotton. To make more sure of the destruction of the germs, we heat the two cylinders filled with carded cotton; and this also causes evaporation of the steam, condensed during the boiling of the water. In some experiments we replaced the cotton with amianthus, in order that we might maintain a higher temperature.

A small suction-apparatus allows the renewal of the air from time to time; a condition that is important for the results of the experiment.

We have thus, then, in a closed space, a liquid which, by boiling, has been deprived of its germs, and into which have been introduced albuminoid substances, without any alteration, which have not at any moment been in contact with the exterior air; and the whole is kept in presence of an air which, before entering the globe, had been sifted by

a thick layer of carded cotton, or of amianthus, heated to a high temperature.

With these conditions, nevertheless, vibrions and bacteria have always developed in this liquid in a few days.

After three or four days, with a temperature of 68° to 86° Fahr., the liquid is slightly troubled; but at this stage we merely find a greater or less number of molecular granulations. It is only about the eighth or tenth day that we can discover mobile granulations, some vibrions and small bacteria.

On exposing to free air a liquid of the same composition as that enclosed in the vessel, and comparing the two liquids, we find that the liquid in the globe is altered much more slowly than the one which has been exposed. The vibrions and bacteria are never nearly so numerous. The proto-organisms of the liquid in the globe are much paler, and less mobile; their movements become more rapid when we agitate them some time with air.

The liquids enclosed in the globes never have the odour of decomposition or of putrefaction.

Out of fifteen experiments which we made, there were only two in which, after ten days, we did not find bacteria. In one of these cases, we had added to the liquid a considerable quantity of sugar; in the other, we had only succeeded in introducing one drop of blood.

The proto-organisms are more numerous, the larger the quantity of albuminoid substances introduced.

We believe it may be inferred from these experiments that proto-organisms may arise and be developed in albuminoid substances protected from air.

ALEX. B. MACDOWALL.

PATHOLOGY.

LEGGE ON THE LIVER IN JAUNDICE.—Dr. J. Wickham Legge has reprinted a paper on this subject from the *British Medical Journal* of May 9 and 16.

After reviewing the etymologies of jaundice and its synonyms, he remarks that the first effect of an obstruction in the bile-ducts is dilatation behind the obstruction. Should the obstruction be in the common duct, it is the gall-bladder which suffers at first. It may become enormously dilated, and be mistaken for ascites. In Cline's case, a male, aged sixteen (quoted by Andree, 1788), the gall-bladder, after tapping, contained half a gallon of bile, and reached from liver to pelvis. Van Swieten records a case of a boy, aged twelve, whose gall-bladder contained 8 lbs. of fluid. This bile may become absorbed, and a colourless fluid take its place, as often happens with gall-stones, constituting hydrops vesicæ fellææ, first noticed by Glisson, 1681. This fluid sometimes contains albumen, sometimes not. Ritter (*Comptes Rendus*, 1872, tom. lxxiv. p. 813) states that some of these fluids contain all the constituents of bile, except the pigment. General experience, however, is that the bile-acids also are absent. This was the case in two examinations made by Dr. Legge. It has been thought that the liver ceased to secrete bile, in cases where the larger ducts are found filled with colourless fluid. Dr. Legge says that bile could be found in the small ducts in a case of this kind recently examined by him. Oskar Wyss's experiments on dogs (*Archiv der Heilkunde*,

1867, p. 469) are instructive in this point of view. He first made biliary fistulæ, and then poisoned the dogs with phosphorus. Though little or no bile flowed from the fistulæ, the dogs became jaundiced. It seemed as if the liver ceased to secrete bile, but it was found that the openings of the smaller ducts into the larger ones were plugged with tenacious mucus, hindering the flow of bile into the larger tubes. Ebstein has noticed the same fact in patients poisoned by phosphorus. The ducts outside the liver often become as large as the middle finger. In animals they are often tortuous, after they have been ligatured. Sometimes the dilated ducts may be mistaken for tumours. Traffelman's case (quoted by Schenk) is often misquoted: He states that in the body of Daniel, Archbishop of Mainz (died 1582) the bile-ducts were found filled with gall-stones, and dilated 'instar utriculi.' Morgani quoting this, changed the last word into 'ventriculi,' and this mistake is still copied. Of modern instances, one quoted by Dr. Halliday Douglas (*Monthly Journal of Medical Science*, Edinburgh, 1852, vol. xiv. p. 97), is of dilatation of the common duct in a girl aged seventeen. By tapping, thirty ounces of fluid were taken away, but nearly half a gallon of yellow fluid was found after death.

The ducts within the liver are often greatly dilated, though the proper parenchyma of the liver prevents such extreme dilatation as that of the exterior ones. In cases seen by Dr. Legge, the dilatation has been uniform or cylindrical. Virchow says it is sometimes saccular, or cystic (*Die Krankhaften Geschwülste*, Band i. p. 254). These dilatations may be as large as a cherry or walnut, and may closely resemble a small echinococcus cyst, only they have no membranous wall. Friedreich (*Archiv für Path. Anat.*, Band xi. 1857, p. 466), describes a cyst, which he believed to be a dilated gall-duct. He found well-marked ciliated epithelium. Dr. Legge thinks this case unique, though in some animals this epithelium is ciliated during the whole of life. He has met with no second case like that of Boismont (quoted by Abercrombie), in which the liver had the appearance of a large undulating cyst, due to distension of all the biliary vessels with dark bile, and wasting of the proper substance of the liver. There was a singular obstruction of the common duct by a membranous band passing over it. Large ducts often open into hydatid cysts and abscesses. Their contents do not help much in the diagnosis. The laminated wall of the hydatid cyst is diagnostic. Joffroy, speaking of abscess, says that no columnar epithelium is found in the limiting membrane of the abscess, but liver-cells are found in various stages. Dr. Legge says if we suspect that we have to do with a dilated duct, and wish to find this columnar epithelium, we must neither wash nor rub the specimens. In ducts measuring four millimètres ($\frac{1}{4}$ inch) he found it easily; not so in those whose diameters were ten millimètres (nearly $\frac{1}{2}$ inch). He says the left branches of the hepatic duct have been more dilated than the right in his cases—probably from the less resistance of the left lobe of the liver. Catarrh due to obstruction often goes on to supuration—the abscesses induced are often multiple. Cruveilhier seems to have been the first to notice this. The abscesses are rarely larger than a hazel-nut. Their mode of origin is disputed.

The liver itself, in cases of obstruction, first increases in size, becomes of a deep olive green colour, and the surface becomes granular. It soon begins to

waste, if the obstruction persist. In all cases of long-continued obstruction, the connective tissue grows, starting from the point of obstruction. In animals Dr. Legge has known the liver to become intensely cirrhotic in fourteen days from the application of a ligature to the bile ducts. [See his paper in *St. Bartholomew's Hospital Reports*, 1873, vol. ix. p. 161.] This overgrowth of the connective tissue was recognised by some of the older pathologists (Albers and Andral). Their changes in the liver cells are less striking. They do not always suffer fatty infiltration, as Leyden taught. Their chief change is atrophy, sometimes becoming only about twice the size of a leucocyte. Dr. Legge finds that in cats all glycogen disappears in a few days after ligature of the ducts, and after the fifth or sixth day glycosuria cannot be set up by irritation of the fourth ventricle. Golowin (*Archiv für Path. Anat.*, 1871, vol. liii. p. 433) states that the bile acids are no longer secreted, when jaundice has been of long duration. This requires confirmation. As regards urea, Dr. Legge has several times found the excretion of this substance to be normal in quantity in complete obstruction of the gall-ducts. Gscheidlen's experiments (*Studien über den Ursprung des Harnstoffs im Thierkörper*, Leipzig, 1871) render the formation of urea and uric acid by the liver doubtful.

In some of these cases the liver-cells seem quite destroyed. The cause of this is doubtful. Dr. Legge thinks Oskar Wyss in error in calling this a *post mortem* change. Bile renders the outline of the cells indistinct, but colouring matters restore it. He has often kept livers some days, without preservative fluids, and could see the cells easily in this way. It is probable that the circulation of blood containing biliary acids may, like other poisons, and like raising the natural temperature of the body (*Trans. Path. Society*, 1873, vol. xxiv. p. 266) produce degeneration of tissues, and perhaps solution of the liver-cells. This appearance, however, is seldom met with, except in acute yellow atrophy, and wants further authentication.

[Dr. Legge's paper contains many valuable references to papers on diseases of the liver, besides those which we have quoted.—*Rep.*]

W. BATHURST WOODMAN, M.D.

POLLARD AND LOCKHART CLARKE ON SUBACUTE DIFFUSE GENERAL SPINAL PARALYSIS.—The following case of this form of disease of the spinal cord is related by Dr. F. Pollard in the *St. Thomas's Hospital Reports*, 1872; the clinical history being supplemented by Dr. Lockhart Clarke's microscopical examination of the spinal cord. The result of which is, we may here note, that the case should be designated one of 'subacute diffused myelitis.'

F. A., a married woman, aged forty-nine, was admitted June 13, 1872. She had had three children, but none for twenty-two years. Her general health had been good until ten months before admission, and there was no history of any blow or fall. At the time mentioned she had a severe cholera attack. The paralytic symptoms commenced a few weeks after this attack, when she noticed that her legs were becoming weak, and seemed to give way under her. The paralysis of the legs increased. Some time afterwards the right arm became enfeebled, and during the two months previous to admission the left arm. She had been subject to cramp-like pains in the back and limbs during the whole time.

On admission, the patient was unable to walk or stand. She could move her legs about in bed to some extent, but stiffly, and with pain and effort. There appeared to be entire loss of cutaneous sensibility in the thighs, legs, and feet. Reflex movements were easily excited. The arms were very weak, the forearms being more affected than the upper arms. She could just raise her hands to her face, but the hands themselves were quite powerless and entirely devoid of squeezing power. Sensation in the hands and forearms was much deadened. The arms and legs were extended and somewhat stiff; they appeared to be much wasted. She complained of frequent pains in the back and limbs, and it caused her much pain if her limbs were moved about or she were turned over on her side. She was quite unable to raise herself in bed, or to turn over without assistance. There was a good deal of tenderness over the sacral and lumbar vertebrae, and to a less extent all along the spine. The urine was occasionally passed involuntarily, and the bowels were much confined. *There appeared to be no signs of mental alienation, no facial or lingual paralysis, no affection of sight or hearing, and the pupils were natural.* While in the hospital the patient became progressively weaker, the legs became powerless, they were often involuntarily drawn up or crossed over each other. The arms and fingers were always extended. Galvanism was tried—the muscles of the limbs seemed to act fairly when the current was passed through the main nerves of the limbs, but very feebly when localised.

This case continued to become worse, with increasing rigidity of limbs and occasional wandering of the mind, and she died in September of the same year.

Dr. Lockhart Clarke describes fully, as follows, the morbid changes in the spinal cord and medulla oblongata removed from the case of subacute diffuse general spinal paralysis. In the *conus medullaris* and the lower two-thirds of the lumbar enlargement, nearly the whole of the anterior grey substance was softened, and in some places quite pulpy. The superficial portions of the posterior columns was in a similar condition. In the upper third of the lumbar enlargement the grey substance was not much altered, but the surfaces of the posterior columns were softened to a considerable degree, and sclerosis, or destruction of the nerve-fibres, with proliferation of the connective tissue, extended deeply through these columns, nearly to the surface of the transverse commissure. The sclerosis, however, was limited chiefly to the wedge-shaped strands on each side of the posterior fissures. This morbid change was everywhere accompanied by an innumerable multitude of compound granular corpuscles of different sizes, by oil-globules, and great increase of connective tissue.

Softening and disintegration was observed in the dorsal region, both in the grey matter and in the posterior white columns, the sclerosis of the posterior strands being still more marked at the tenth dorsal vertebra than it was below, and had extended to the lateral columns. Above this level the sclerosis of the posterior strands was still more marked, as was also the softening of the surface of the columns, more especially anteriorly, and the whole of the anterior grey substance. The pia mater over the posterior columns was considerably infiltrated and thickened.

In the cervical enlargement the grey substance was very little affected, but the posterior and lateral columns were more severely damaged here by sclerosis, than in the inferior regions of the cord.

In the medulla oblongata the posterior cuneiform strands were entirely destroyed below the points of the anterior pyramids. The change extended over the *caput cornu posterioris* to the lateral columns. The sclerosis affected similarly the surface of the restiform bodies and posterior pyramids, continuously with the posterior wedge-shaped strands.

In all the sclerosed parts the blood-vessels had lost their natural structure, and were frequently severed into small fragments by progressive disintegration.

The nerve-cells that were not destroyed by the inflammatory action were somewhat altered in appearance. They contained more brown pigment than usual, and were in the first stage of disintegration. The whole of the changes are considered by Dr. Clarke to have resulted from inflammation of the substance of the spinal cord.

[Before concluding our report of the above case, we would call attention to the want of precision that prevails in our use of the term 'general paralysis.' It may suffice for the present purpose to point out that the case before us is selected from several in a paper entitled 'Varieties of General Paralysis,' of which Dr. Pollard has enumerated twelve. It would be beyond our objects critically to analyse the characters of these, but to any one who may consult the memoir itself it will be obvious that to only a few of them can the term 'general' be strictly applied, and then with qualifying epithets. In this country, the term general paresis, or paralysis, is usually confined to one form of mental disease, since paralysis sooner or later makes itself apparent in the group of morbid phenomena. The forms of this kind of 'general paralysis' may be as numerous as the individuals. Our continental brethren are more precise in their nomenclature, and speak definitely of 'general paralysis of the insane,' or of 'encephalite interstitielle diffuse.' Other forms of paralysis should be defined as reflex, spinal, progressive, ascending, (of which the above case may be taken to be an instance) diffused, ataxic, etc. The several pathological conditions giving rise to the several distinct forms of paralysis could, of course, be made the basis of further classification, not, however, always available for practical purposes, since the structural lesion may be obscure, and only discoverable after death. We are largely indebted to Brown-Séquard, Duchenne, Charcot, Vulpian, and others, for their labours in the direction of precise pathological definition.—*Rep.*]

W. B. KESTIVEN.

SMITH ON FATTY DEGENERATION OF THE HEART IN YELLOW FEVER.—Dr. Bat Smith, of Mobile, offers an explanation of the process of 'true fatty degeneration of the muscular structure of the heart,' which he describes as present in the majority of fatal cases of yellow fever (*New Orleans Medical and Surgical Journal*, May, 1874). The author points out that this morbid change is due to a perverted nutrition, continuing for a longer or shorter period; and, in the case of yellow fever of a malignant character, he finds the source of this functional disturbance in a pathological condition of the sympathetic. In all the cases of yellow fever which he has examined, *post mortem*, during the last two years, Dr. Smith has found very evident active congestion of the sympathetic ganglia, throughout the whole extent of the chain.

The sympathetic possesses nutritive vasomotor functions, and a heavy congestion will be the con-

sequence of a general impairment of the physiological condition of its centres. Impaired aëration of the blood follows, expressed by fatty degeneration, and the heart, being the hardest-working muscle of the body, will be the first to suffer.

Dr. Smith is inclined to ascribe the high temperature of yellow fever and the hæmorrhagic tendency observed in it, in part at least, to the same paralysis of the ganglionic chain of the sympathetic.

J. MITCHELL BRUCE, M.D.

PERLS ON INTRAUTERINE FIBROMA OF THE ORBIT.—At the sitting of the Königsberg Society of Medical Science, on February 9 (*Berliner Klinische Wochenschrift*, July 20), Herr Perls demonstrated, as a contribution to the causation of growths developed in utero, a case of fibroma of the orbit, with infiltrating ostitis of the roof, and a fibromatous thickening of the dura mater. The case occurred in the practice of Herr Loch, of Danzig. The infant was born with marked exophthalmus on the right side, and died within twenty-four hours.

The external upper half of the cavity of the orbit was filled with a rounded smooth solid mass, about two inches in diameter, thicker behind than forward. The periosteum was lost in the mass of the tumour. The external rectus passed over it, separated from it. A transverse section displayed a very hard smooth fibrous surface, chiefly of an opal yellow, in places of greyish-green colour. The lacrymal gland was absent. Under the microscope it presented a hard fibrous structure, with a few cells; chiefly, however, composed of fine fat-molecules and a few vessels. In places there were small bunches of fat-globules. The dura mater exhibited a small round thickened spot, about the size of a sixpence; its upper surface was not smooth, but uneven, and beset with fine proliferations of areolar tissue. When the dura mater was stripped off, it was about two millimètres in thickness, and of a very hard thick fibrous consistence, of a greenish-grey colour on section. The place where the dura mater was attached presented a somewhat crumbling soft irregular surface, and a portion was adherent to it. The under surface, with which the tumour was connected, exhibited a similar condition. The separation from the bones both of the dura mater and tumour was easily effected, and its surface appeared on both sides partly finely and partly coarsely fibrous. The pores were covered and filled up by a soft tissue in most places. The middle portion of the orbital roof was very thin and fragile, and showed several small irregular holes permeating its whole thickness, equally filled up with the soft tissue. This soft tissue presented the small cells and vascularity of a granulation-membrane, and the surfaces of any section showed the bones to be more or less infiltrated with this material, and that principally in the lacunæ (Howship's). On colouring with carmine, the membrane that filled up these lacunæ was found to consist in part of small cells, or large cells containing many nuclei, whose form often exactly corresponded with the depressions in the remaining bone-substance. The structure of the bone everywhere beyond these lacunæ was normal.

Herr Perls remarked on the extreme rarity of any growth occurring during intrauterine life, except dermoid cysts and erectile tumours. He believed this to be an unique preparation. Whether the preparation in the Göttingen Collection of an enormous (osteogenous?) fibroma on the scalp of a child was

intrauterine or not, was not evident from the description given by Förster.

W. C. GRIGG, M.D.

MATERIA MEDICA AND THERAPEUTICS.

DOBELL ON A NEW REMEDY FOR HAY FEVER AND SNEEZING.—Dr. Horace Dobell writes thus in the *Pharmaceutical Journal* of June 27.

At this season of the year, when 'sneezers' and sufferers from 'hay-fever' are in the depths of their miseries, it is merciful to make public any reasonable suggestion for their relief. I have, therefore, much pleasure in being able to bring forward a little contrivance and a prescription, by the combined use of which immense comfort may be given to many sufferers.

The prescription is as follows:—

| | |
|---|------------|
| Chloral hydrate and camphor (of each). | 16 grains. |
| Carbolic acid | 20 „ |
| Pure morphia | 12 „ |
| Oleic acid (enough to dissolve the morphia) . | 20 „ |
| Castor oil (the clearest and finest) | 7 drachms. |

Rub well together to make a lotion.*

The 'contrivance' is for the efficient application of the above remedy, and consists of a miniature bottle contained in a little box-wood case, so that it can be carried easily in the pocket. To the lid of the box is attached the cork of the bottle, and to the cork, in the same fashion as the spoon of a cayenne-pepper cruet, is fixed a little club-shaped rod of polished ivory, long enough to reach to the bottom of the bottle, and also to the upper extremity of the nostril. The little bottle is kept half full of the lotion above prescribed, and the little rod immersed in it. Directly the patient feels the tickle or other signal of a coming sneeze, he uncorks his bottle, withdraws the ivory club, wet with the oleaginous lotion, and gently pushes it up the nostril till it reaches the seat of the sneeze-signal; there it should be gently pressed so as to apply the lotion to the part. After this the club is withdrawn and returned to its little bottle of fluid, where it becomes at once charged for a fresh application. As often as the sneeze threatens, the operation should be repeated. Very often one application will keep off a threatened fit of sneezing altogether, even though its first effect may be to excite a sneeze.

I have requested Messrs. Savory and Moore to keep this little appliance ready-made and charged with the lotion, so that it can be sent by post without difficulty or delay. It has been of so much comfort in cases within my own practice, that I am sure it is worth while for any one who has not yet found a remedy to give it a trial.

In cases accompanied by much throat-irritation, it is advisable to combine with this treatment the use of the 'Lozenges for Postnasal Catarrh,' prepared from a prescription formerly published by me (*On Winter-Cough*, etc., 2nd edition, p. 204), and always kept ready-made by Bell, Savory, Squire, Corbyn, Hanbury, and other leading chemists.

I may add that, when there is great prostration,

* As different perfumes affect different patients peculiarly, no scent is added in this formula; but anyone who prefers it, may have it scented by the addition of whatever perfume is known to suit best.

and a tonic is required, tincture of eucalyptus globulus will sometimes answer better than quinine, especially if there is much feverishness.

None of these remedies should be used without consulting the doctor in attendance on the case.

DYER ON PODOPHYLLIN FOR ACUTE RHEUMATISM.—Dr. R. F. Dyer, of Ottawa, Illinois, writes in the *American Quarterly Journal of Medical Sciences* for July, 1874, that about five years ago he accidentally discovered that the active principle of Podophyllum peltatum promptly relieved the pains in acute rheumatism. He usually follows it with 'alkaline treatment,' and, if the pains return, recurs to the podophyllin. He commences with light doses combined with Dover's powder, at intervals of two or four hours, until the bowels are moved very freely several times. In some cases he has given it in divided doses for three days before it took effect. The more severe the case, the more is required. Sometimes two or three evacuations relieve; at other times, eight or ten are required. After the bowels are evacuated, if relief be not obtained, he continues the use of the medicine in divided doses, not large enough to produce vomiting. If the pain return in two or three days, he repeats the treatment. He had thought that perhaps it was the free purgation that afforded relief; but, upon trying active catharsis from other remedies, he is fully satisfied that there is some specific influence exerted by the podophyllin.

OBSTETRICS AND GYNÆCOLOGY.

PETER ON PUERPERAL DISEASES.—Dr. Michel Peter, in an article in *La France Médicale* for June, 1874, treats of the causes of puerperal convulsions and their cure. The convulsive movements are the result of uræmic poisoning, which may arise either from long-standing kidney-disease—the excretory action of the kidneys being still further diminished during the process of gestation by the pressure of the gravid uterus on the renal veins, or from congestion of the kidneys through pressure where no previous disease has existed. Should this condition be allowed to remain any length of time, it will eventually lead to permanent structural changes of the kidneys. This is shown by the fact that eclampsia at the fifth month is a comparatively mild affection, but the nearer it approaches to the end of gestation the more formidable does it become. The uræmic renal hyperæmia is in a more advanced stage at the ninth than at the eighth month, and at the seventh than at the sixth month. The treatment should be to relieve the congestion, which is best effected during the progress of an attack by free bleeding, so as to make an impression on the general circulation, and by relieving the arterial tension to produce a contraction of the vessels of the kidneys. The ex-traction of blood has equally as great an effect upon the arterioles of the kidneys as on those of the brain or skin. Bleeding is not only a most powerful agent in the arrest of convulsions; but also, by relieving the congestive condition of the renal organs, leads to their cure. Whether the state of the kidneys be one of advanced disease, or of merely temporary congestion, the treatment should be the same. In the latter instance, it effects a permanent cure; in the former, it places the woman in the best position for prolongation of life.

When one bleeding has succeeded in arresting the fits, but has left the patient in a comatose state, the operation should be repeated, which is best done by means of leeches behind the ears. This method of free and repeated bleedings is advocated by Stulz, Dubois, Depaul, and Cazeaux.

Chloroform, although a very potent remedy to arrest the attacks, cannot from the pathology of the affection cure it. In the same position stands chloral. The inhalation of chloroform is by no means devoid of danger in certain stages of eclampsia. When the face is cyanotic, indicating pulmonary engorgement, the stupor produced by it but intensifies the toxic effects of the uræmia, and hastens the death of the patient. This the author has seen in more than one instance. Again, even when it has succeeded in relieving the fits, the patient has invariably aborted shortly afterwards from the effect of the unrelieved uræmic poisoning.

[The reporter cannot approve of the estimate here formed of the efficacy of chloroform and chloral in eclampsia. He has had several opportunities of seeing a combined treatment of chloroform, chloral, and opium in the several forms of this affection. The results in every case have been good. The amount of albumen in the urine in all cases was great, and in one it became almost solid on boiling. During convalescence, the albumen entirely disappeared. The cases were primiparæ. The only fatal case which the reporter has witnessed was where bleeding and ice-bags to the spine were employed. In the above-mentioned cases there was no œdema of the legs or any signs of anasarca; whereas, with extensive œdema of the legs, and in two cases of universal anasarca, there was no eclampsia. The reporter is inclined to believe that the effusion of serum into the cellular tissue, instead of being regarded as a sign of danger, should be viewed as a remedial measure, and as indicating a favourable prognosis rather than the reverse.—*Rep.*]

W. C. GRIGG, M.D.

SCHURIG ON CÆSAREAN SECTION.—Dr. Fritz Schurig gives (*Fahresbericht der Gesellschaft für Natur und Heilkunde, and Philadelphia Medical Times*) an account of this operation, as performed by him on a patient thirty-seven years of age, in whose case safe delivery was impossible by reason of a condition of osteomalacia. The procedure was as follows. An incision, six inches in length, was made in the line of the linea alba, when the uterus presented itself in a condition of complete ante-version, with the ovarian ligament and the broad ligament protruding through the wound. Afterwards the uterus was turned, and, being pressed against the abdominal walls by an assistant, was also opened by an incision. The placenta proved to be attached anteriorly, and after its removal the living child was seen lying with its buttocks forward, and with the head somewhat turned to the left, owing to its unfavourable position for several days previously. The uterine wound bled freely. The abdominal wound was closed by ten sutures, aided by strips of adhesive plaster. Shortly after the operation the patient succumbed, owing to loss of blood.

The *post mortem* examination showed the bones highly hyperæmic, the form of the pelvis indicative of osteomalacia, and the last lumbar vertebra strongly pressed downwards, as after spondylitis. The various bones of the pelvis were movable at their junctures. Four months previously to delivery, the patient ex-

perienced a sensation as if something in the pelvis had become sprung, or as if the pubic bones had become partly separated.

HUBER ON EXTRACTION BY CEPHALOTRIPSY. Dr. Huber states that, on account of the frequent occurrence of the flattened and rickety pelvis in his neighbourhood, he has performed cephalotripsy on eleven occasions, and trusts his experiences may be of service to others. He employs Scanzoni's instrument. There are three errors which beginners are likely to make.

1. The blades are not passed up high enough, and this is more particularly the case when the head, from compression, has become much elongated.

2. The handles are not sufficiently depressed. Hecker maintains that the instrument should be so depressed as to be almost in a vertical position.

3. Traction is begun before the brain has all come away.

Should a removal of the bones be necessary, he considers that Simpson's cranioclast is superfluous, as also Mesnard's forceps, and Boer's pincette; and that after the bones have been once or twice well squeezed they can be more readily removed by the fingers, and with less damage to the maternal parts than by any other method.

Still there are cases with the most skilled operator, in which the cephalotribe is not available as an extractor. In one case, the author failed to extract after a twelve hours' attempt. A putrid child was afterwards spontaneously expelled.

Kilian's proposal to leave the fœtus to decompose and to spontaneous expulsion, is, on account of extreme danger, not feasible. The much recommended use of the sharp hook in text-books is a most questionable proceeding, not only on account of the great difficulty experienced in its application, but also the extreme danger of its injuring the maternal parts. Huber agrees with Cazeaux in proscribing it, and replacing it by a curved blunt hook. This instrument is best applied by putting the finger into the mouth of the child and passing the hook with the other hand, and fixing its point into the most accessible posterior nares; even if the parts be torn, no great injury will accrue, and the other nares will still be available. The writer believes he is the first to suggest the passing of a curved blunt hook into the posterior nares as a method of extraction. He tried it in one case with complete success, where he had failed after using every other method.

VON HASELBERG ON OVARIAN PREGNANCY.—

At the meeting of the Berlin Obstetrical Society on January 27 (*Berliner Klinische Wochenschrift* June 15), Herr von Haselberg demonstrated a preparation of ovarian pregnancy. The woman was twenty-six years old, and had given birth to two children previously. She thought herself pregnant about three months. She was suddenly seized with great pain in the abdomen, accompanied by a bloody discharge *per vaginam*, and the passage of a clot. The pain increased; and when first seen the patient was pale and pulse frequent, the abdomen very sensitive. *Per vaginam* a tender, uneven, movable tumour was discovered. She died four days afterwards. The *post mortem* examination discovered a considerable amount of recent and old clots in the pelvic cavity. Behind the uterus there was a tumour about the size of a fist, with two small rents on its upper surface; within was an ovum containing a fœtus about 1·2

inches long. No tube could be found. That an ovum had developed in the ovary, was proved by discovering a corpus luteum alongside of the cavity.

W. C. GRIGG, M.D.

LINN ON THE NORMAL PULSE, RESPIRATION, AND TEMPERATURE OF PUERPERAL WOMEN.—Dr. G. Wilds Linn, late resident physician to the Philadelphia Hospital, reports (*Philadelphia Medical Times*, May 9) his observations on temperature in a series of twenty-four normal puerperal cases occurring in the Philadelphia Hospital. The observations were begun immediately after delivery and continued for nine days, during which time the patients were kept in bed. The temperature was observed in the axilla at 9 A.M. and 8 P.M. While the cases were under observation, no alcoholic stimulants were allowed. The diet consisted of milk, eggs, beef-tea, and mutton, with coffee or tea, and bread, toasted or plain, with butter.

The conclusions deduced from these observations are the following.

1. The normal temperature of the puerperal woman is only about 6° Fahr. higher than that of the healthy human being, if we accept the statement of Wunderlich, that the mean normal temperature is 98·6° Fahr.

2. The normal pulse of the puerperal woman is not more frequent than that found under ordinary conditions in a state of perfect health.

3. The number of respirations is increased, if the statement of physiologists be received, that the number of respirations of the healthy woman ranges from eighteen to twenty per minute.

4. The generally received opinion that the secretion of milk is attended by an increase in temperature of one or more degrees, and an increase in the frequency of the pulse of 10 or 12 beats per minute, is erroneous.

5. A temperature of 100° Fahr., or a pulse of 100 a minute, in the lying-in woman, is indicative of some pathological process, which it behoves the accoucheur to discover at once, in order that proper measures may be taken to arrest its development and remove the evil.

These observations are in accord with those previously published by Barker, Winkel, Wolff, and Baumfelden.

MARTIN ON A CASE OF ADHERENT OVARIAN CYST, CURED BY INJECTION OF A SOLUTION OF CARBOLIC ACID.—Dr. Edward Martin reports (*Berliner Klinische Wochenschrift*, June 15, 1874), the case of a young woman aged twenty-five, of delicate constitution. The ovarian tumour was ascertained to spring from the left side, and to be attached to the uterus. The uterine sound passed nearly three inches forwards, and to the right. Any movement of the tumour affected the uterus. At the urgent request of the patient, she was operated upon. An incision about four inches long was made in the linea alba. The tumour was then found to be so firmly adherent to the abdominal walls, that any attempt at its removal would have been fraught with great danger. An opening a little more than an inch long was made into the cyst, and about a quart of a brownish glairy fluid, mixed with small blood-clots, was let out. An examination of the cyst showed it to be fixed to the abdominal walls, and to the uterus to a large extent. Two strong elastic catheters were fixed in the cyst, and the wound closed by metallic sutures. The next day, a solution of carbolic acid

in water (0.25 per cent.) was injected into the cyst, and continued until what ran out of the other catheter was quite clear and free from any odour. That which first came away was turbid. This was repeated three times a day. The solution on the next day contained $2\frac{1}{2}$ per cent. of carbolic acid, which was afterwards increased to 10 per cent. The temperature never exceeded 101.5 Fahr., and the pulse 120. The tumour gradually became less and less, and on the thirteenth day it was about the size of an apple, and the discharge was free from any odour. The injections were then reduced to twice a day. On the twenty-fourth day the catheters were removed. The small fistulous opening soon closed; and when last seen, five months afterwards, she was completely restored to health and strength.

The only point of interest was the uninterrupted convalescence, which was attributed to the frequent washing out of the cyst with the carbolic acid lotion. At no time did the urine show any trace of carbolic acid, although a strength of 10 per cent. was for some days injected. The remains of the former tumour were still evident behind the cicatrix when last examined, but nothing was discoverable *per vaginam*.

STÜMKE ON A RARE FORM OF MALFORMATION OF THE FEMALE GENITALS.—This case was reported by M. Stümke at the meeting of the Obstetrical Society in Berlin, on January 18, 1874 (*Berliner Klinische Wochenschrift*, June 15). It was not discovered until the forceps were being applied. It consisted of an hypertrophy of the preputium clitoridis, which was as large as the forefinger, and attached to the posterior fourchette. It was torn through by the passage of the child's head; and both ends were afterwards cut off by the scissors.

HARTWIG ON A NEW INTRAUTERINE PESSARY. Dr. Hartwig, of Berlin (*Berliner Klinische Wochenschrift*, July 20, 1874), describes a new form of intrauterine pessary. To the button of an ordinary intrauterine stem there is screwed a corresponding excavated plate; between these the ends of a gum tube are firmly squeezed, in which a piece of whalebone or a watch-spring has been introduced. By means of this screw there is an elastic half hoop on one side of the double button, which, according to the way it is introduced, will look either upwards or downwards. The advantages to be gained by this instrument are the following.

1. The uterus is not immovably fixed, but capable of equal movement with its natural supports.

2. The vaginal walls are not put on the stretch, as the stem comes to its aid.

3. It does not prevent coitus in many cases. If desirable, another loop can be added to it, making it a double-looped one.

MAYER ON DOUBLE POLYPUS.—At the meeting of the Berlin Obstetrical Society on January 27 (*Berliner Klinische Wochenschrift*, June 15), Herr Mayer exhibited a double polypus springing from one root, about four-fifths of an inch in length. This he considered a very rare accident. In the same person, two years previously, he had removed a polypus with a broad base about the size of a child's head. He then noticed two hard masses in the cut surface, which probably was the origin of this double polypus.

W. C. GRIGG, M.D.

DERMATOLOGY.

ESPINET ON LEPROSY IN THE WEST INDIES.—The following is an abstract of a Report of the Leper Asylum at the Port of Spain, presented to the Legislative Council of Trinidad, by the Medical Superintendent, Dr. Espinet, dated April 30, 1874.

Of 116 cases, 89 men and 29 women, 27 had been admitted last year. Of these, 16 presented the tuberculated form of the disease, 10 the anæsthetic; and in the remaining case the two conditions were combined. Six patients were discharged, relieved by treatment.

1. Male, aged twenty-one, coolie; immigrant from India. He had been ill two or three years before admission in 1872. He had brown, scaly anæsthetic patches on the trunk, scrotum, and upper and lower extremities. Cashew-nut oil was applied locally, and twenty drops of Donovan's solution given twice a day for three weeks. When he left, by his own desire, all the patches had recovered some sensibility.

2. Male, aged twenty-eight, also Indian; had an ulcer on one foot, and two large scars, only slight anæsthesia. The diagnosis was doubtful; perhaps there was syphilis. He was treated locally with black wash, and internally with five grains of iodide of potassium twice a day. He was attacked by pleuro-pneumonia, and cured with blistering and tartar-emetic. He left with the ulcer healed.

3. Male, aged thirty-eight, a third coolie; had tuberculated leprosy with dysentery. He was much improved by ten months' stay in the Infirmary, with good food and without any drugs.

4. Male, aged thirty-six, coolie; had leprosy nodules, ulcers, and anæsthetic patches. He improved under quinine and meat diet.

5. Male, aged twenty-nine, coolie; had lepra anæsthetica, with a small ulcer on one foot. Cashew-nut oil was applied, and Donovan's solution, iodide of potassium, quinine, arsenic, and iron, were given internally. He left improved in health, but with the cutaneous disease unchanged.

6. Male, aged twenty-six, creole; had lepra anæsthetica, maculosa, et squamosa, and an ulcer on the heel. He was relieved without specific treatment, and on leaving the asylum married a leprosy woman, the subject of the disease in its anæsthetic and ulcerative form. They have had two children, neither of whom have shown signs of inherited disease: the elder one is four years old.

Of the 116 patients, 18 died in the asylum; 3 from exhaustion; 5 from diarrhoea and dysentery; 5 from disease of the lungs; 3 from gangrene; 2 from ascites.

Of the 86 inmates at the date of report, 24 were natives of India, 56 of Trinidad, 3 of China, 2 of Barbadoes, and 1 of Africa.

Dr. Espinet believes that leprosy is on the increase among the coolies. It appears almost, if not quite, invariably to show itself some time after their arrival in the island from India. As leprosy is common in some parts of Hindoostan, it is possible that some of them bring a hereditary taint with them; but Dr. Espinet thinks more influence is due to their insufficient and unvaried diet (chiefly or entirely rice), their foul habits, and especially their custom of eating dirt. No instance of the disease has yet occurred in a coolie child; the children are better fed and cared for than their parents.

In one case, a leprosy boy, ten years old, con-

tracted 'yaws' from an ulcer on the face of a child whose mother was subject to the same disease, and the boy transmitted yaws to two other lepers.

In conclusion, Dr. Espinet points out that the two measures called for to combat leprosy in Trinidad as elsewhere, are (1) improvement of the abundance and variety of food of the poorer population, and (2) sequestration of those already attacked, so as to prevent its propagation by hereditary transmission.

VIDAL AND HILLAIRET ON THE TRANSMISSION OF RINGWORM.—MM. Vidal and Hillairet have added (*L'Union Médicale*, June 30) to the cases reported in a former number of the MEDICAL RECORD (July 1, p. 407), one in which tinea tonsurans was transmitted from horses, and one from a calf to human beings; and the latter observer added the following. Six railway workmen came to him with 'pelade' (*Porrigoides* of Willan, *area* Celsi), and he found that a cat which was sick and losing her hair was constantly lying on their caps. [The cat, however, was not examined.]

HIRSCHBERG ON XANTHELASMA PLANUM ET TUBEROSUM.—Dr. Hirschberg publishes (*Berliner Klinische Wochenschrift*, July 20, 1874) the case of a man, aged thirty years, who from the age of eight has been the subject of a remarkable affection of the arms and legs, which has gradually increased to its present dimensions. The skin is in many places deeply pigmented, and is also covered with flat yellow patches or with raised nodules, which are most prominent about the ham and the elbow. Some of them are separate, others are clustered into great masses. From microscopical examination of a piece of the affected skin seven years ago, Virchow and Leber described it as *Xanthelasma multiplex* [*Vitiligoidea plana et tuberosa* of Addison and Gull.—*Rep.*] or *Fibroma lipomatodes*. The fibrous structure with oil-drops which they found, was again seen in a nodule excised in the present year by Dr. Hirschberg. An apparently similar growth had formed on the cornea, of the right eye as early as 1864. This was removed by the late Professor von Gräfe in the following year, and again on its return in 1867. At that time there were yellowish flat spots on the left cornea, which Von Gräfe regarded as early stages of the same disease; but at the present time they are still in the same condition, though the tumour of the right eye returned and became so large, that the entire globe was lately removed by Dr. Hirschberg. The growth had invaded the whole of the cornea and filled the anterior chamber. On section it showed a tissue rich in cells of varied size and form, many of which were in a state of fatty degeneration; it was said, however, to agree with the structure of the cutaneous nodules. [This case is evidently the same as that described and figured by Virchow in 1871 (vol. lii. of his *Archiv*, p. 504.) There is no account of any jaundice or other accompanying symptoms. The result of the microscopical examination of the nodules in this case, and the fact of the yellow patches being found on the cornea (even if the identity of the tumour which destroyed the right eye be doubted) add fresh proof that this remarkable disease is not an affection of the sebaceous glands, as asserted by Hebra, Neumann, and Dr. Tilbury Fox. The microscopical characters agree with those first described and figured by Dr. Moxon (Pavy on *Vitiligoidea plana et tuberosa*, *Guy's Hospital Reports*, 1866), and since by Professor Waldeyer (Virchow's

Archiv, vol. 51, p. 318), confirmed by the observations of Dr. Frank Smith (*Journal of Cutaneous Medicine*, Oct., 1869), Kaposi (Hebra's *Hautkrankheiten*, II. Theil, p. 257), Mr. Howse (Fagge on *Xanthelasma*, *Path. Trans.*, 1873, p. 244), and several other observers. It has been well described as atheroma of the skin. While small patches of xanthelasma on the eyelids are very common, multiple nodules as in this case, and in three of those first recorded (by Addison and Gull in the *Guy's Hospital Reports* for 1851), are much more rarely met with. *Rep.*]

LANCEREAUX ON PARALYSIS AND CUTANEOUS DISEASE.—*L'Union Médicale* for June 30, 1874, contains the following case by M. Lancereaux. A woman, aged thirty-seven, keeper of a wineshop, had her cellars emptied during the insurrection of the Commune. After a month of great mental depression from this cause, she was suddenly attacked by left hemiplegia, without loss of consciousness, followed by aphasia. In six months she had recovered her speech, and in two or three more the paralysis had almost disappeared. From this time, however, her sight became weak, she felt severe pains in the loins, and afterwards in both legs, and a cutaneous eruption appeared on the feet. Nearly two years after the apoplectic attack she came under M. Lancereaux's care. There were then alopecia, left ptosis, with dilated pupil, and external strabismus. There was no palsy of the portio dura, and little or no remains of hemiplegia, but weakness of all the limbs. Sensation was perfect everywhere. She had severe stabbing pains in both legs. There was a scaly eruption with yellow crusts over the soles and backs of both feet, with slight redness and desquamation up the legs. While she was under observation large bullæ formed on one foot, and there was so much inflammation around it that it resembled erysipelas; but the inguinal glands became also enlarged and painful. Two months later a chronic slightly scaly eruption appeared first on one and then on the other hand, occupying the palms and wrists, and looking like syphilitic psoriasis. Meanwhile the patient kept her appetite, and the urine, pulse, etc., continued normal. The toe-nails became longer, thicker, and more distorted, the feet became completely covered with small white scales, with occasional bullæ, and on removing these the skin was found red, smooth, and tense, as if it had been burnt. The toes gradually atrophied, and the lymphatics could be felt as hard cords up to the inguinal glands. The affection of the hands also spread up to the elbows. About eighteen months after her first attack, the patient was seized with spasms of the neck and limbs, became unconscious, and died in twelve hours. The organs of the thorax and abdomen were found to be healthy; but for some unexplained reason the brain and cord were not examined. M. Lancereaux inferred that all the phenomena were due to some chronic disease of the nervous centres, affecting the nutrition of the skin by trophic nerves. [The unfortunate omission makes this remarkable case of less value than it should have been. The reporter has seen at least three cases which he believes to correspond to that of M. Lancereaux. They were all in women, and began with coldness and numbness of the fingers, followed by redness and desquamation with anæsthesia and atrophy. In the earlier stage the appearance was like that of a chilblain, afterwards more like chronic eczema squamosum, and finally, in one of the cases, a patient of Mr. Cooper Forster's, at Guy's Hospital,

more than one of the phalanges shrivelled and fell off. In this case there was a similar slow atrophy and dry gangrene of the toes. In none of these patients were there any symptoms of disease of the nervous centres, and it may well be that the cutaneous affection described by M. Lancereaux, as well as the hemiplegia, may have been both due to disease of the arterial system rather than to any primary lesion of the brain.—*Rep.* P. H. PYE-SMITH, M.D.

REVIEWS.

De l'Homme : Principes de Climatologie Médicale et leur Application aux Climats Sud-est et du Sud-ouest de la France. Par Sir ALEXANDER TAYLOR. Pp. 19. Pau. 1874.

In this little *brochure* we have the matured views of Sir Alexander Taylor on the climate of Pau. Sir Alexander has done very much for Pau what Dr. Henry Bennet has done for Mentone, and has made it a popular residence for the English.

The views which he lays down in this paper are mainly those which he expressed in his well-known work on the climate of Pau, and which continue to guide him in his practice in that city. But his opinions are here made to rest on a more general and philosophical foundation, and he discusses at length the four temperaments—the sanguine, the phlegmatic, the choleric, and the melancholic, and the principles on which climates should be selected, in order to suit each temperament. The following short extract gives the gist of the pamphlet.

‘The climates of the south-east and of the south-west of France may be divided into two classes: those which are exciting, and those which are sedative. In exciting climates are to be found invariably the following atmospheric conditions. Great dryness, air highly charged with electricity, the presence of ozone, and during the spring sharp and irritating winds in the south-east of France, as Nice, Mentone, Cannes, Hyères, Montpellier. In sedative climates we find a sort of neutral state of the atmosphere, a very moderate amount of dryness, great absence of free moisture, rareness of free electricity, or of ozone, and a great calmness of the air, as at Pau.

‘If we wish to stimulate languishing functions, to quicken the too slow circulation of the blood, to awaken the dormant energy of the nervous system in melancholic and phlegmatic temperaments, we must not send such cases to the sedative climate of Pau.

‘If, on the other hand, we wish to moderate nervous or muscular excitement, to quiet inflammatory tendencies, and give some repose to the constitutions of the choleric and the sanguine, the physician consulted, if he understands the case fully, will not send them to exciting climates like those of Nice, Mentone, Cannes, Hyères, and Montpellier.’

Such are the commonly received views on the subject. Whether too strong a line is not usually drawn between exciting and sedative climates, is another question. J. MACPHERSON, M.D.

Mélanges de Pathologie Comparée et de Tératologie. Par le Dr. O. LARCHER. Paris, 1874.

The second fasciculus, recently published, of Dr. Larcher's *Mélanges de Pathologie Comparée et de Tératologie*, is entirely devoted to the pathology of birds.

The first memoir treats of foreign bodies in the digestive tract, comprising distension of the crop with substances of food; fatal inflammation set up in the crops of young birds by the voracious swallowing of insect larvæ; the various parasites which infest the crop; lodgment of foreign bodies in the ventriculus succenturiatus [or proventriculus], and in the true gizzard, and entozoa in the intestinal tract beyond the pylorus.

The second memoir is devoted to the affections of the female generative organs, and includes abnormal conditions of the ovary, of the oviduct, and of the cloaca. A lithographic plate is given of prolapse and hernia of the oviduct [bird not named], with retention of the egg; also of a duplicature of the external orifice of the cloaca in a hen turkey.

The commencement, also, of a memoir is given on the affections of the circulatory system in birds.

The principal value of this little *brochure* lies in the copious references in foot-notes to the literature and collections of all countries which bear on the subject. J. C. GALTON.

MISCELLANY.

In the week from July 19 to 25, there were thirty-two new cases of small-pox in Stockholm.

THE School of Pharmacy of Paris has at the present time 500 students attending it. In addition to these must be reckoned the students attending the Provincial Superior Schools of Pharmacy.

JABORANDI.—M. Coutinho has placed a certain quantity of this much talked of drug on sale at Mariani's, the chemist on the Boulevard Haussmann, in Paris. Our French *confères* will therefore now have a better opportunity of arriving at a just conclusion as to its alleged sudorific and sialogogue qualities.

A MEDICAL CONGRESS will be held in Forlì in the week from September 16 to 22. This will be immediately followed by the Meeting of the Italian Medical Association, which will commence in Bologna on September 22. During the later meeting, the statue of Morgagni, in Bologna, will be unveiled.

PROFESSOR MOMMSEN has been elected Rector Magnificus of the University of Berlin, by a majority of twenty-three votes against nineteen. His principal opponents were Professors Bardeleben and Helmholtz. Professor Hirsch has been elected Dean of the Faculty of Medicine in the same University.

OPIUM SMOKING IN THE UNITED STATES.—Official reports state that 250,000 pounds of opium are annually imported into the United States, being ten times as large a quantity as the imports of ten years ago. Barely a third of the amount is used for medicinal purposes; the rest is consumed by the opium-smokers.

L'HOMME À LA FOURCHETTE.—At a recent meeting of the Paris Société de Chirurgie, M. Labbé gave the latest intelligence concerning this man. A considerable swelling had appeared in his right hypochondrium; and, the formation of an abscess appearing to be likely, M. Labbé thought it advisable to expedite the process by the application of blisters and iodine. These methods, however, had the precisely contrary effect of producing the resolution of the swelling. The patient scarcely suffers anything except after a full meal, when he always bends himself to the left side, a position from which he derives relief. M. Labbé intends to content himself by merely observing the condition of his patient, without undertaking any operation.

ON August 2, the Frederick-William Medico-Chirurgical Military Institute, in Berlin, celebrated its seventy-ninth, and the Medico-Chirurgical Academy its sixty-third anniversary. The festival was attended by a large number of military medical officers, and by general officers, and by professors of the University. In welcoming the guests, General-Surgeon Dr. Boeger regretted the loss which the profession had sustained by the death of Dr. Loeffler. In the last year the Academy has been attended by 203 students. Professor Virchow delivered an address on the essential nature of infectious diseases, according to the most recent researches.

HIPPOPHAGY.—The consumption of the flesh of horses and their congeners, mules and asses, is decidedly on the increase in Paris, a result doubtless assisted by the proverbial excellence of the French sauces. Returns show that the flesh of 2,111 horses, asses, and mules was sold to the Parisian public during the first quarter of the current year, against 1,275 in 1872, and 980 in 1870. A similar increase of consumption is also reported from the provinces. 'Honour be to him to whom honour is due' has been carried out by the Society for the Propagation of the Practice of Eating Horse-flesh, who, at their last meeting, conferred medals on M. Decrose, a military veterinary surgeon, its founder; and on M. Condere, who was the first to preserve horse-flesh, or at least the first to do so avowedly. It was stated at the meeting that horse-flesh preserved in February, 1871, by M. Condere's process, and opened in April, 1874, could not be distinguished from beef preserved according to the best methods now in use.

THE MEDICAL ARMY OF PARIS.—M. Maxime du Camp, the painstaking historian of modern Paris, gives us some information in an article lately published in the *Revue de Paris*, of the amount of the army employed in combating disease and death in that city. From its pages we learn that the gay city contains 1,726 doctors and 179 officers de santé, or medical men not possessing doctor's degrees. The medical necessities of the Parisian population likewise find work for 561 midwives, 353 dentists, 528 herbalists, and 734 apothecaries. With regard to the drugs vended by the last-mentioned class, M. Maxime du Camp gives a curious experience of the variation of prices sometimes asked for the same article. He wanted 100 grains of dioscorides, and was asked for them 20 francs by one chemist, and 10 francs by another, and finally found a druggist who manufactured them and sold them to him for the modest sum of 19 sous, or ninepence-halfpenny English money.

SPIRIT PHOTOGRAPHS.—Dr. J. H. Gladstone, F.R.S., has called attention to some photographs of fluorescent substances, which the editor of the *Philadelphia Medical and Surgical Reporter* thinks may help to explain the mystery of the so-called spirit photographs of which we have lately heard so much. It appears that the fluorescent substances, such as bisulphate of quinine, or uranium glass, have the power of altering the refrangibility of the violet or chemical rays of light; hence, although paper painted over with bisulphate of quinine will look nearly white, it will appear in photographs as if it were nearly black. Dr. Gladstone has exhibited some photographs of ornamental design traced on white paper with bisulphate of quinine; although the designs were nearly invisible to the eye, in the photographs they were boldly visible. A colourless solution of bisulphate of quinine was placed in one glass, and some ink in another glass; when both glasses were photographed they came out equally black. Dr. Gladstone said that once at the seaside he painted a pattern with bisulphate of quinine upon paper, and took the paper to a photographer to be photographed; he objected, because there was nothing on the paper, but on trying the experiment he found out his error. It was stated that some kinds of varnish possess a similar power of affecting the refrangibility of light.

THE RECENT EPIDEMIC AMONGST HORSES IN NEW YORK.—An investigation into the recent wide-spread disease among horses has lately been made in New York by order of the Board of Health of that city. The writer of the report on the subject regards the disease as the exact counterpart to epidemic influenza; and, while admitting that the simultaneous seizure of horses all over the city did not arise from contagion, he maintains that it spreads from city to city and state to state, solely and uniformly through the transportation of the poison by a diseased subject. Thus it would seem that he believes some occult atmospheric condition to be necessary to the prevalence of the disease, yet not of itself able to originate it, for he says that strict quarantine invariably protects. In other words, contagion is necessary, while yet in a given city or stable the spread of the disease confessedly outruns the possibility of contagion.

A NIGHT medical service has just been organised at St. Petersburg by the medical men of that city; an arrangement which meets a real want of the public of the Russian capital, who, however, had hitherto not taken the necessary steps to provide it. Russian medical legislation does not allow liberty of work to medical men, who when required, either by a sick person or any one believing himself to be ill, are not permitted to refuse help. The physician, surgeon, accoucheur, midwife, or assistant who should either refuse to act when called on, or neglect to do so, is punished by a fine, on the first occasion of from 5 to 10 roubles (17s. 6d. to 35s.), on the second occasion of from 10 to 15, and the third time from 50 to 100 roubles; whilst the physicians and surgeons who are in government employ may be deprived of their office. These laws are sanctioned by usage, and no later than this year two Russian physicians were tried for an infraction of this law, and one of them condemned for having refused to afford assistance to an invalid during the night. The *Courrier Médical Russe*, whence we obtain our information, insists on the necessity of abolishing these coercive measures directed against medical men; the more so that at the present time everything relating to the public health in Russia is regulated by municipalities in the cities, and by the territorial, cantonal, and departmental councils in the provinces. The same journal also urges that in England custom no longer sanctions coercive laws directed against medical men, whilst in Prussia they were erased from the statute-book in 1869.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & CO., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & CO.—Calcutta: THACKER, SPINK & CO.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & CO.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & CO., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S.W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, AUGUST 26, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

ON THE PHYSIOLOGY OF THE CORTEX CEREBRI.* By JAMES J. PUTNAM, M.D.†

ALL those of the profession who interest themselves in physiological matters are already familiar with the experiments, made first, some years ago, by Fritsch and Hitzig of Berlin, and latterly repeated with greater elaboration by them, and by Ferrier of London, which seem to prove that the cortex cerebri is not, as had been long believed, or at least not over its whole extent, incapable of responding to other stimuli besides those to whose influence it is regularly subjected.

On the contrary, it appears that, when a weak current of electricity is applied to certain pretty sharply defined points which lie mainly in the convolutions bordering on and anterior to the fissures of Sylvius and Rolando, certain groups of muscles on the opposite side, and sometimes on both sides of the body, may be thrown into contraction. The important bearing of these observations upon cerebral physiology and pathology has not failed to gain for them the close attention of neuro-pathologists everywhere, and especially of Dr. Hughlings Jackson, of London, who sees in them the verification of some clinical theories of his own. The observations themselves have received corroboration from all sides, but recently an important criticism has been made on them by Dr. Eugene Dupuy,‡ and by MM. Carville and Duret,§ and, indeed, by Hitzig himself in speaking of the experiments of Ferrier,|| viz., that it is impossible in using induction currents (Hitzig employs galvanic currents), to confine the irritation to limited districts of the cortex cerebri, and that the muscular contractions which attend, at least Ferrier's method of irritation, are due partly (Hitzig) or entirely (Dupuy) to the irritation of nervous masses which lie buried deeper.

The experiments here recorded were undertaken for the purpose of testing that point; but it may be well, before describing them, to examine a little the adverse testimony just referred to. The criticism of Hitzig was called out by the fact that Ferrier's centres, though in the main corresponding with his, occupied a larger area, and that their position, as observed in cats, differed from that in dogs more than the other differences between these animals would have led him to believe. Into the examination of these points we do not undertake to enter.

* *Boston Medical and Surgical Journal*, July 16, 1874.

‡ *Examen de quelques points de la Physiologie du Cerveau*. Paris. 1873.

§ *Gazette Médicale de Paris*, January 10, 1874. Vide also review of both in the *Archives of Neurology and Electrology*, vol. i. no. 1, May, 1874.

|| *Berliner Klinische Wochenschrift*, February 9, 1874.

On the part of Carville and Duret, the criticism was founded mainly upon the results of some experiments in which platinum needles, connected with a sensitive galvanometer, were introduced to different depths into the brains of animals, while the cortex was faradised in the usual manner; and they assert that the galvanometer needle was deviated, even when the distance between the platinum needles and the electrodes which furnished the current amounted to several inches. From these and other facts, to be referred to later, they drew, among others, these conclusions.

1. The cortical substance of the hemispheres is not excitable; it is insensible, and does not contain special motor centres.

2. The effects produced by faradic currents are due to direct excitation of the corpora striata and crura cerebri, as the currents penetrate to these organs.

They also conclude that faradic currents, however feeble, are diffused over the surface of the brain, from one point to another.

Although the distinction is not made in their report, it is most probable that Carville and Duret used the primary, and not the secondary induction currents, contrary to Ferrier's habit; otherwise they would not have been able to detect their presence by the galvanometer, for the needle of this instrument is not deflected by the currents of short duration, whose direction is constantly changing, such as are obtained from the secondary induction coil. This is in so far of importance that the secondary currents, owing to their greater tension (power of overcoming resistance), make their way less weakened by diffusion directly through the tissue separating the wire electrodes; for although, in traversing any conductor electricity diffuses itself to some extent over the whole mass, yet the degree to which it does so is inversely proportional to its power of forcing a direct passage between the points of entrance and exit, and this power, thanks to the greater number of turns of wire of which the secondary coil is made up, belongs to the secondary induction current in greater degree than to the primary (extra) current.

Dupuy* was led to much the same conclusions as those stated, finding, as did also Carville and Duret, that 'it is possible to excite, by the irritation of any point whatever of the cortex cerebri, contractions, affecting sometimes a whole limb, which is generally the fore leg and on the opposite side of the body;' also 'that (while the irritation was being made as usual) a galvanoscopic frog-preparation was thrown into contraction when its nerve touched the cortex cerebri at a point far removed from that irritated,' and, further,† that nerves at the base of the brain, which have been previously cut through to prevent the transmission from above of nervous excitation, can be excited electrically when applications are made to the surface of the brain in the usual manner, showing to how great an extent diffusion of electrical currents may take place.

That these results were obtained as stated we have no difficulty in believing, but we do not admit that they justify the conclusions drawn. The real question plainly at stake is, not, 'can we produce effects due to irritation of distant parts while irritating

* As well as for other reasons, not discussed here because not bearing on the point under consideration.

† So stated at a recent meeting of the New York Society of Neurology and Electrology. Vide *New York Medical Journal*, July, 1874.

definite points of the cortex cerebri,' which is unquestionably the case, but, rather, 'can we irritate the cortex cerebri to the extent necessary to produce the results claimed, without at the same time irritating deeper seated structures enough to call out their functional activity,' and this possibility is not refuted by the experiments of Dupuy, or Carville and Duret, but receives affirmative support from our experiments, although few in number. Our plan was, to find, which was always possible, centres for definite, and nearly or quite uncomplicated, movements, and the minimal current strength that was necessary to produce these movements, and then, with a sharp knife, to make a cut underneath them, leaving a good-sized but thin (by estimation 1 to 2 millimètres thick) flap, which contained, in each case, the supposititious centre. Having done this, we found that if we irritated as before, leaving the flap *in situ*, the movements before observed did not occur.

We then turned the flap up and irritated below it. The same strength of current generally failed here also to call out the movements, but they always appeared when the strength was slightly increased; not so, however, when the flap was turned back and adjusted, and the electrodes applied on its surface as at first, repeated trials being attended with the same results. The irritations were made with the current from the secondary coil of a Du Bois-Reymond's induction apparatus, run by a single Léclanché cell, and the minimal current, which was found efficient, was strong enough to be felt distinctly by the tongue, scarcely, if at all, by the finger,* *i.e.* of about the strength that Ferrier also found usually sufficient.

The animals experimented upon, three in number, were dogs. The method was that usually followed, and no accidents occurred which materially interfered with the investigations. The movements obtained were, in the first experiment, extension of the opposite fore-leg; in the second, extension of opposite fore-paw, flexion of fore-leg at elbow, extension of leg at shoulder, partial extension of paw, these different phases following each other slowly, and the full result only occurring when the irritation had lasted a certain time; in the third, extension of the fore-paw of the opposite, sometimes also of the same, side, and occasional slight movements of hind legs; in the fourth, well-marked closure of the opposite eye, without any other movements with the exception of occasional struggling.

Subsequent examination showed that the centres which we found agreed quite well with the corresponding ones found by Ferrier, in one instance, more closely, apparently with that given by Hitzig.

One experiment, given somewhat in detail, will serve as a type of all.

June 6.—A middle-sized, healthy dog was etherised, a large portion of the skull laid bare from the median line down to the zygomatic arch on the right side, and a small piece of bone trephined out from the middle of this surface. The opening so made was enlarged with bone-forceps to the diameter of about 1.5 centimètres, the dura mater removed, and the exposed portion of brain sketched. Muscular bleeding was checked by perchloride of iron; that from the membranes, which was considerable, by light pressure with sponges.

Centres were sought for in vain over this surface,

with irritations varying in strength from $D = 15.3$ centimètres to $D = 12.9$ centimètres.* Once only all the muscles of the body were thrown into spasmodic contraction, which lasted after the cessation of the irritation, passing over into general struggling which made more ether necessary.

The hole was then enlarged to about 3 centimètres in diameter, and the search continued, but, at first, without success. This was probably because the unusually great tendency on the part of the animal to struggle violently, though probably not suffering much pain, obliged us to keep it thoroughly etherised, whereas it is only during incomplete etherisation that the centres, or most of them, are irritable. At the thirteenth point of application, with the weak irritation $D = 14.8$ centimètres, we obtained firm closure of left eye, the animal being pretty well under ether, and quiet.

| Centimètres. | Result. |
|---------------|---------------------------------------|
| With $D = 16$ | Same as before, but less well marked. |
| $D = 15.3$ | Ditto, better marked than last time. |

(From this point on the animal remained, at least at the moments of experimentation, pretty quiet. The ether was discontinued so far as to ensure that the eyes should be open, or partially so, at the proper moments.)

As superficial a section as possible was then made (at most 1 millimètre thick), but the flap left *in situ*.

| | Centimètres. | Result. |
|--|--------------|--|
| Application made on top of flap | $D = 14.8$ | o |
| Application made on exposed surface after reflection of flap | $D = 14.8$ | o |
| Application made on exposed surface after reflection of flap | $D = 12.8$ | Left eye firmly closed. |
| Application made on top of flap after replacement | $D = 12.9$ | o |
| Application made below flap again | $D = 12.9$ | Closure of eye as before. |
| Application made on top of flap | $D = 12.9$ | o |
| Application made below flap | $D = 12.9$ | Closure of eye as before. |
| Application made on top of flap | $D = 12.9$ | Possibly closure of eye to slight degree. |
| Application made below flap | $D = 12.9$ | Closure of eye as at first, though not so strongly marked. |

Application made on top of flap $D = 12.9$ o

No other movements occurred, at the moments of experimentation, that could be regarded as due to the irritation of the brain, or that materially complicated the results stated.

These experiments were made at the physiological laboratory of the Harvard Medical College, with the kind assistance of Professor H. P. Bowditch and Dr. Wm. James. Since their completion, the gratifying statement has come to our notice that essentially the same method has been employed by another observer, with the same results. (Braun, *Eckhard's Beiträge zur Anatomie und Physiologie*, vii. 2; also *Centralblatt*, Berlin, June 13, 1874.)

* In no case was it necessary to make the secondary coil overlap the primary, or even to come within an inch of doing so.

* D represents the distance between the similar ends of the two coils. $D = 0$ would indicate that the secondary coil was slipped entirely over the primary. When $D = 7.5$, the anterior end of the secondary coil was just level with the posterior end of the primary.

THE PLAGUE IN MESAPOTAMIA AND NORTHERN AFRICA.

[The following interesting article is taken from the *Times* of August 17.]

The re-appearance of plague in Mesopotamia and in Northern Africa is a fact of peculiar interest, even if regarded solely from the historical associations of the malady. The locality of re-appearance in Mesopotamia is contiguous to the scene of the outbreak of 1867; the locality of re-appearance in Northern Africa was the scene of the outbreak of 1858. Plague is believed to have disappeared from Egypt in 1844, and it is not known to have existed in Northern Africa from that date to 1858. In the last-named year the disease broke out in the Regency of Tripoli, at Bengazi, the ancient Berenice, and spread over that portion of the district of Barca which was known among the ancients as Cyrenaica. Mesopotamia had been free from plague upwards of thirty years (no certain case had been known since 1834) when, in 1867, the disease appeared, and spread to some extent among the Arab tribes inhabiting the marshy district which lies west of the Euphrates, between the ruins of Babylon and the great shrine of Shiite pilgrimage, Nedjef (Meshed Ali).

The present appearance of plague in Tripoli begun at Merjeh some time during the first quarter of the year. Merjeh is situated to the south-east of Bengazi, about twenty hours distant, on the plain of the same name. It is a new town, built on the site of the ancient Barca. When the place was visited by Hamilton in 1856, a fortress, begun a year before, and 'several small houses in progress, destined to form the nucleus of a town,' alone existed. Now the number of houses is said to be 64, including certain excavations in the rocks, beneath the fortress, used as dwellings, and the general state of squalor seems to rival that of Bengazi, known among the Turks, from its persistent plague of flies, as the 'fly kingdom.' Thirty cases of plague, twenty-seven of which were fatal, have been verified by a medical commissioner, Dr. Laval, as occurring between the 7th and 21st of June, among a population of about 300. On the last-named date, Dr. Laval, unhappily, was himself struck down with the disease, and he died on the 27th.

In 1858, the plague which then prevailed in the district extended to Merjeh. The plain, or as some term it, the valley, of Merjeh, is an extensive tract of 'mingled pasture and cultivation,' hemmed in by richly wooded hills. Although from its extent designated a plain, and from its being surmounted by hills, a valley, yet, say the Beecheys, in their narrative of exploration on the north coast of Africa in 1828, this plain and valley, from its being situated 'in the top of a chain of mountains of no inconsiderable elevation, must also be considered as a tract of table-land raised far above the level of the sea.' The plain is a favourite resort of the Bedouin tribes in the summer months, from the numerous pools and lakes formed there by the water coming from the neighbouring hills. The different travellers who have visited the plain describe it and the district which surrounds it as of great beauty; and those geographers who hold that the gardens of the Hesperides were in the Cyrenaica appear to have much to justify their belief in certain physical characters of the district.

The outbreak of 1858 occurred in the midst of famine, caused by a continuance of drought in several successive years, and the consequent diminution and

ultimate destruction of crops and exhaustion of supplies. Famine is not stated to have preceded or accompanied the existing outbreak of plague in Merjeh.

The scene of the present diffusion of plague in Mesopotamia is on the lower Euphrates, south of Musseyib. The disease first showed itself at the close of February or the beginning of March last among the Affij Arabs, who occupy the northern portion of the great marshes on the east bank of the river. The infection quickly spread to the neighbouring tribes, and, attacking both banks of the river, it extended along the stream from Devanieh upwards to Hillah. On the west bank of the stream the infection spread also to Nedjef (Meshed Ali) and Kerbella (Meshed Hussein)—to the edge of the desert, in fact, traversing the district which was the scene of the outbreak of 1867.

Since the commencement of June, plague does not appear to have extended beyond the area described, and there is reason to hope that it is now dying out within it. No clear knowledge exists of the loss of life occasioned by this diffusion, and it is hardly likely that such knowledge will be obtained. The Medical Commission appointed by the Ottoman Government to investigate the diffusion has been able to satisfy itself of the nature of the disease, but has been foiled in its attempts to ascertain the extent of prevalence among certain tribes and in certain localities.

The recurrence of plague among the tribes inhabiting the marshes of the Lower Euphrates, as the recurrence of the malady in the district of Barca, is highly suggestive of inquiry regarding the development of the disease, if it were possible to carry out such an inquiry among the isolated and savage tribes affected. The Affij Arabs, among whom plague first appeared this year on the east bank of the Euphrates, seems to have like habits and like surroundings as the Beni-Taraf Arabs, among whom the disease first appeared on the west bank of the river in the outbreak of 1867. Both tribes live in the marshes, and for a third of the year amid the annual inundation of the Euphrates; both occupy reed huts covered with matting, and both cultivate and live largely on rice. Mr. Kennett Loftus, who visited the Affij Arabs twice, once in 1849 and again in 1854, describes their 'fragile towns' as consisting entirely—

'Of reed huts, the reeds being tied in large bundles and nearly arched overhead. This primitive construction is covered externally with thick matting, impervious to rain. The riches of the Affij are indicated by rows of huge reed cylindrical baskets, containing the grain upon which they subsist. Rice is produced in great abundance along the edges of the marsh; but the whole of their fields were at the time of our visit and for a third of the year entirely under water. Communication is kept up, as on the marshes of Hindieh, by means of long, sharp, pointed terradas, constructed of teak, and measuring twelve or fourteen feet long, by a yard in width.' (*Chaldaea and Susiana*, p. 91.)

The same writer's description of the Hindieh marshes, on the west bank of the Euphrates (the scene of the outbreak of plague in 1867), as seen from Birs Nimrud, deserves quotation.

'The view from the summit of the Birs Nimrud is very extensive, and its utter desolation has been the theme of frequent observation. No one can stand there and survey the scene around without being

struck with the literal fulfilment of Isaiah's prophecy—"I will make it a possession for the bitter, and pools of water; I will sweep it with the besom of destruction, saith the Lord of Hosts." Spreading out like a vast sea upon the north and west is a marsh, which all the labours of the ancient and modern rulers of the country have never been able to subdue. In certain seasons the waters of the Euphrates rise above their ordinary level and flood the whole surface of the lowlands of Chaldaea, confirming every word of the prophet. Bordering upon this marsh, a few spots attract the eye and relieve the long level of the horizon. Due south stands the little tomb of the prophet Ezekiel, and at the distance of fifty miles, in the mirage of early morning, may be discerned the mosque of the sainted Ali, glistening like a speck of gold as the beams of the rising sun play upon its surface. Nearer at hand, on the north-west, are the twin domes of Kerbella, the burial-place of Ali's slaughtered sons. The edge and islands of the marsh are at times dotted with encampments of Khuzeyl Arabs, and with the telescope may be distinguished the numerous flocks of sheep and camels, while the hum of busy voices can be distinctly heard a distance of full six miles across the waters.' (P. 33.)

About the same time that the outbreak of plague occurred among the Affij Arabs, and the disease appeared in Northern Africa, it was also rumoured that plague had shown itself at Revanduz, in Turkish Kurdistan, and in the vicinity of Bana, in Persian Kurdistan. Both places are on the confines of the district which was the scene of the outbreak of 1870. At the close of that year, after an interval of forty years, plague broke out among the villages situated between the rivers Jagatu and Tatawa, south-east of Lake Urumiah. It appeared first in those situated in the swamps, and of which the inhabitants were employed in the cultivation of rice. During the winter the infected villages were cut off from the surrounding country by the snow, and when communication was reopened with them they were found to have been well-nigh depopulated by the disease. As the spring advanced and the roads become free, the inhabitants took to the hills and migrated into neighbouring districts, carrying with them the infection, which now quickly spread over a considerable extent of the mountainous region. The inhabitants of this part of Kurdistan escaped the horrors of the famine which prevailed in Persia in 1871, but it is not so certain, as some believe, that the communities first attacked by the plague did not suffer much privation. The outbreak had been preceded by murrain among the cattle and by defective and diseased crops; and it is probable that the populations of the infected villages suffered great straits during the winter of 1870-71.

Famine during the past winter (1873-74) was widely present in Asia Minor, but neither the district of Kurdistan from which the rumour of plague now comes, nor the district which is the scene of the present outbreak on the Lower Euphrates appears to have suffered, and no report of plague has come from the famine-stricken districts.

It might seem from the recent recurring outbreaks of plague as if the disease were about once more to become a prominent epidemic. The possibility of a reappearance of the disease in an epidemic form has not been overlooked by the different writers on the subject; the subsidence and even apparent extinction of the malady in countries where it was once endemic

not being regarded as affording any surety against its recurrence, so long as the sanitary condition of the inhabitants remains unchanged. The limitation of the recent outbreaks to communities removed from ordinary observation, and among whom the first beginnings of the disease could not be traced, suggests that plague, although now more rarely observed in a diffusive form, may not so entirely have disappeared from its former seats of prevalence in the Levant as is commonly believed, and that these recent outbreaks may possibly be recrudescences rather than re-appearances. Whichever be the truth, the practical lesson is the same; and Europe, while not regarding these outbreaks with indifference, ought to contemplate them without anxiety. In the present state of medical and sanitary knowledge and practice, plague among European nations should excite no greater emotion, as it does not call for other measures of precaution or treatment than typhus. In the Turkish dominions in Asia and Africa, the case is, however, different. There races and populations, as in the present infected districts, have to be dealt with, among whom the sanitary regulations of a civilised community are impossible. But the sanitary organisation of the Turkish Empire seeks to close the different routes by which the infection of plague may travel from an infected locality, and it is now attempting to bring the various centres of Mahomedan pilgrimage in its dominions under systematic medical and sanitary supervision, so as to prevent them becoming as heretofore great *foci* of epidemic diffusion.

As we write a report has reached this country of the appearance in Western Arabia of a disease resembling plague, and the Egyptian Government has put in operation the most stringent measures for isolating the affected districts, and for placing under supervision, and subjecting to quarantine, arrivals from the Hedjaz in Egyptian ports. It has also decided, according to official report, to cut off all communication with the Regency of Tripoli by land and by sea. The locality in which the disease suspected to be plague has shown itself in Western Arabia is Dogar (or Doga), a town built of brushwood and reeds, and lying at the foot of the hills, a day's journey north-east of the fort of Gofudah. Here the encampment of an Arab tribe has been attacked. If the suspicion that this disease be plague should be confirmed, it is to be feared that the disease will also be found to exist in other parts of Arabia, as a consequence of dissemination from the Lower Euphrates and from Meshed Ali and Kerbella.

IMPURE MILK A SOURCE OF DISEASE. By T. D. CROTHERS, M.D., OF ALBANY, NEW YORK.*

Milk, as an article of diet, is almost universally used. It is one of those nutrient substances which are subject to rapid changes of chemical and physiological principles, depending upon various causes, of which climate, water, food, and surroundings are most prominent. Recently it has been proved that milk may be the active agent or vehicle for the transmission of disease. The many cases reported during the last year give strong evidence that milk is an agent of far greater danger, and more widely diffused as a source of disease, than we are aware of.

* *Philadelphia Medical and Surgical Reporter.*

The following case called my attention to this subject, and is presented not as peculiar and anomalous in any way, but one that can be readily confirmed by the experience of others.

Through January and February of this year I was called to prescribe for severe attacks of diarrhoea, occurring in a healthy family, well nourished, and living in good hygienic surroundings. This family had never suffered from this disease before, and it seemed more violent among the younger members than in those grown up.

The disease yielded readily to the usual treatment with evacuants and astringents, but returned as soon as the medicines were discontinued. A careful inquiry into the habits of this family indicated nothing unusual, except the free use of milk as an article of food. On Sunday, milk was made a prominent dish at dinner. It was noticed that the days following would be marked by an increase of the disease, unless checked by medicines. The milk was said to be pure, because it came from one cow kept in the neighbourhood. With these hints, I made a visit to the stable, where I found a small, ill-conditioned animal, standing in a close, filthy stall, ill-ventilated, and containing hardly room enough to turn about. The food of this cow was garbage from the street, consisting of vegetables in all degrees of decomposition, cooked and raw, alternated with brewer's grains once per day. Water was given in the food, but occasionally a pail was brought in, depending on chance and circumstances. The stable was cleaned once or twice a week, and the doors were closed to keep in some hens. The walls of the building were brick, and the ventilation or renewal of the air, must come from the open seams in the door and window. In this place, for over three months, this cow had been confined; her body was filthy, and the hair stood up in all directions. The amount of milk given varied from ten to eighteen quarts per day, and looked blue, although it tasted sweet. Here, the condition of the cow and surroundings, with the kind of food eaten, fully warranted the belief that the milk was impure and the cause of the diarrhoea. This diagnosis was confirmed by the complete disappearance of the disease when the family stopped using the milk.

No analysis of this milk was made, nor microscopical examination. But, on general principles, its fatty matters were deficient, with poverty of its normal constituents; and the microscope might have revealed animalculæ; but with these facts the nature of the poison would still be uncertain. Dr. Chandler, of New York, failed to find any specific poison in milk known to be impure. Other chemists have failed in like manner, giving strong hints that the cause is more subtle, and beyond our present limited means of observation. In this case, the impure milk acted as an irritant, causing a low grade of inflammation, a certain forerunner to other lesions.

A significant case, conveying a similar hint of obscure cause traceable to bad milk, came under my observation. An old gentleman, previously well and strong, while convalescing from a severe attack of intermittent fever, was ordered to use milk freely, by his physician. Four days after he began to use milk as a medicine, he was attacked with exhaustive diarrhoea, resisting all medicines, and terminating fatally in six days. The diagnosis was obscure, but subsequently it was ascertained that the milk used came from a cow kept in a similar condition as the one we have described. The family of the owner of

the cow, who used this milk, likewise suffered from diarrhoea, a striking confirmation of the probability that the impure milk of this cow was the cause of death. The later history showed that the diarrhoea disappeared when this cow was turned out in the yard, and given better food, and more cleanly surroundings.

Another case in the practice of a friend in this city is further corroborative. A middle-aged man suffering from diabetes for three months, was placed on a milk treatment, consisting of large quantities of milk daily. Chronic diarrhoea came on the second week after the treatment began, and grew worse rapidly, terminating in enteritis, exhaustion and death, four weeks after. The milk came from swill-fed cows, in close, dirty stalls, ill-ventilated, unhealthy, and diseased, without question impure and poisonous; giving strong probability that the active cause of death in this case was the milk.

There are three ways in which impure milk may be a source of disease, namely, chemically, physiologically, and psychologically.

It is well known that the *chemical* elements of milk depend upon certain conditions and surroundings which are clearly traceable, and may be well understood. Of these, the age, vigour, and health of the cow, with the quality of food, water, exercise, and pure air, are prominent factors. A deficiency of any of these will be followed by change in the quality of the milk. This is illustrated in the care and attention of stock-raisers, who, when they wish to produce a fine, well-developed animal, give particular attention to the food and water of the cow, allowing the calf to nurse direct, rather than be weaned and raised on inferior milk deprived of its fatty matters. It is well understood that all cows raised by the latter methods (artificially) are wanting in vigour, and give milk likewise deteriorated. Also there are many reasons for believing that milk from such cows is more susceptible to chemical and physiological changes, and more dangerous as a vehicle or source of disease.

The vigour and health of nursing children is in direct ratio to the quality and quantity of milk. The experience of every day indicates the perils which children are exposed to from this source, seen in both mother and nurse. Also it suggests, with startling significance, the increased danger when milk is used from cows.

Some remarkable experiments on this subject were conducted by M. Decaisne, of Paris, during the siege of 1871, and detailed in a paper before the Academy, of which a good abstract may be found in the *Half-Yearly Compendium* for January, 1872. He sought to show the influence of insufficient food on women's milk. Prefacing his paper with observations of Dumas, Payen, and Boussingault, in which were shown the fact that a cow gave healthy milk in exact proportion to the surplus of food beyond what was necessary for its own maintenance. If the animal was kept upon food barely sufficient for proper nourishment, the milk produced must be at a loss of animal tissue, with general deterioration of the milk and also of the cow. Milk formed at an expense of the nutrients and tissues of the body, has less caseine, butter, sugar, and salts, while the albumen will be increased. It follows that the value of milk must depend upon the excess of food beyond what is required by nature to keep up the normal vigour of the body. The author proceeds to show that nearly an analogous condition

exists in women, which he demonstrated by experiment during the siege of 1871, in forty-three cases of nursing women.

These cases were in private families, and suffered from want and insufficient nourishment. Some of the results of his observations are stated thus.

1. Insufficient food always produces a diminution in the normal quality of the milk, also a variation of its chemical constituents; such as an increase of albumen and diminution of caseine, butter and sugar. The proportion of albumen, in such cases, is generally in inverse ratio to that of the caseine.

2. The health of the mother declined with this variation in the quality of milk, depending upon age, hygienic conditions, constitutional vigour, etc., until the milk became minimum in quality and quantity. Also that these effects are seen in four or five days from the time of using an insufficient diet.

These experiments indicate that a similar imperfect condition of health and surroundings, in both animals and human beings, destroys the normal quality of the milk, and also encourages and predisposes to organic lesions.

Physiologically, milk may be normal in quality, yet possess the poisonous matter. Several striking instances have been noticed in Ohio and Indiana, where epidemics called 'milk-sickness' prevailed. This disease was extremely fatal to men and animals. In animals it was characterised by tremblings and fever, followed by congestion and death. In man the premonitory symptoms were obscure for some time, then a violent and intense fever came on, particularly among those who had used freely the milk from these cows. Where the animals were not attacked no cases occurred in man. These epidemics appeared in malarious regions almost exclusively, and when it ceased to exist among animals, likewise died out among men. The source of the disease was from the milk of these cows, but the ultimate cause was never clearly made out.

The instances of typhoid fever-germs being communicated through milk have been so recently discussed in medical literature that they are familiar to the profession generally. A mention of two most prominent examples will aid in a better understanding of this subject. An epidemic of typhoid fever which occurred near Glasgow, Scotland, in 1872 and 1873, indicated the prevalence of this fever in thirty-two out of thirty-nine families which were supplied with milk from one dairyman. Families supplied by other milkmen were singularly exempt. A milk census revealed that a large per cent. of the families supplied by this man were attacked at different times of the year with this fever. The family of the dairyman were also attacked, particularly those who had used the largest amount of milk. How the milk became the agent for propagating fever-germs is not mentioned, but evidently through adulteration with water.

Another case in the healthiest suburban section of London, which occurred last year, places the whole subject beyond all question. Five hundred cases of typhoid fever were found distributed in one hundred and four families, ninety-six of which were supplied with milk from one dairy. The contagion was traced directly to the water used for washing the cans and retained in the milk, the water being previously polluted by sewer drainage. The details of these cases are before the profession, and have suggested the inquiry whether other diseases, as well as typhoid fever, may not be transmitted in this way.

It has been asserted that drinking water polluted with fever-germs taken up by the cow, will pass off in the milk, producing fever, etc. Also, that cheese and butter made from dangerous or impure milk will likewise transmit poison germs. Cases marked by violent cramping and purging have been traced to the milk used, which was found to contain animalculæ, supposed to be taken up in the drinking water and developed in the system. Dr. Brown, of Gault, Ontario, reports two very striking cases of this kind.* Vogel, years ago, showed that vibriones in human milk arose from a condition of malnutrition. Dr. Gibbs found two genera of animalculæ present in milk, where the health of the mother was disordered by prolonged lactation. Other authorities have shown that milk may contain animalculæ as well as poisonous germs equally dangerous.

In Herkimer county, in this State, a large dairyman, who kept his cows confined in a filthy stable during the spring, suffered annually (with other members of his family), from a low type of continued fever. The families of two workmen who used this milk also suffered. The milk from these cows was charged with a pungent faecal odour, which the workmen sought to destroy by chemical means. For several years this condition existed, and the cause was supposed to be malaria. Four persons out of three families died, and those who had used the milk freely suffered largest. The physician used milk as a nutrient and medicine in all these cases, but no relief followed until the cows were turned out to the fields. Last year a thorough cleaning and ventilation of the stables took place, and was continued daily, resulting in a disappearance of this fever, for the first time in five years. Here the faecal gases of the foul stables impregnated the milk and was the active cause of fever. Observation will show that these cases are common, and are seldom recognised. Every farming community where milk cows are kept in stables, will furnish examples of different and mixed forms of fevers, which take their origin in this way.

These cases might be multiplied almost indefinitely, in single instances, and in local epidemics, but for our present purpose may be all summed up in one head, namely:—That milk physiologically may hold in suspension and transmit typhoid fever and malarious germs, animalculæ and poisonous faecal gases, all of which can be determined beyond doubt.

There is another source of disease, less frequent and more obscure, which I shall term *psychological*, because it affects the nervous system and its functions.

The milk contains some element, produced by the violent emotions of the mind, and that is directly poisonous; a familiar illustration is that of milk, when the mother is violently agitated, causing convulsions and death in the child. The text-books give particular caution and stress on this point, yet an hour after, when the emotions have subsided, the peril seems to have passed away. We are yet ignorant of the nature of this poison, which seems to have such a peculiar action on the nervous function. At a late clinic at the Albany Hospital a case was presented of a child six years old, suffering from epilepsy. The history indicated that the child was in health up to a certain time, when the mother, labour-

* Canada *Lancet*, August, 1872. *Half-Yearly Compendium*, January, 1873.

ing under intense excitement, put the child to her breast; soon after the convulsions came on, which developed into a full case of epilepsy. A case of chorea, now under my care, can be traced back to nursing the child when the mother was violently excited. Other cases have been noted, of feeble and broken down nervous systems in children, which were referred back to this same cause, with great probability of correctness.

We are more or less familiar with the profound and often fatal disturbances produced on the system of nursing children by the pregnancy of the mother.

Cases have been reported where nursing children have been seized with convulsions and death, proceeding from the difficult and painful menstruation of the mother. The influence in both of these conditions is physiological as well as psychological.

The same disturbing influence or elements, although less marked, may be seen in cows, and the milk possesses the same abnormal conditions.

A gentleman of this city was advised to secure the milk of a young blooded cow for his infant child. A cow whose first calf was running by her side was purchased, and the calf taken away; and his servant was ordered to milk her, bringing the milk direct to his house. Two months later this child, who was previously healthy, was broken out over the body with a strange undefinable rash, which finally developed into pustules, called by the physician scrofula. Following this came a fever which seemed to affect the brain and nervous system. In the meantime the bowels suffered from intestinal irritation, alternately constipated and relaxed. Various consultations were held by the family physician, and extensive medication followed. The result was that this child, for the year or more while using this milk, was under the constant care of physicians. And, after the second year, had a weak, broken-down nervous system, with frequent pustular eruptions over the body. This was the more remarkable as no other children of this family of five were afflicted in this way, and both parents were healthy.

Subsequently it was ascertained that this cow was driven into a close stall, and whipped into subjection to allow the milking to go on; and for the entire season this process was one of force and more or less brutality. Under these circumstances the milk was made poisonous by the nervous condition of the cow. This inference seems to be borne out by the history of the case, and confirmed by the fact that other children of the same family, brought up on milk from one cow, furnished by a dairyman, were healthy and strong.

A similar instance came under my observation, of a farmer, who, by the advice of his physician, procured the milk of an intractable cow, who had, from vicious habits, been considered unfit for the dairy. This cow, being of the Alderney blood, was thought to give richer milk. The milking was attended with much excitement, and the child to whom the milk was given suffered from gastro-intestinal irritation, and what was called scrofulous ulcers, during all the time of using the milk. Two years later this child was presented at the Albany hospital clinic with symptoms of chorea, a weak, nervous system, and low tone of physical vigour—an exception to the other children of the same family.

An illustration, more obscure, but pointing to the same cause, was noticed in this city three years ago. A highly respected milkman, with a large class of

customers, sold out his business, with cows, to a brutal, intemperate man, who continued the business as before. From some chronic disease he was unable to leave the farm, hence he gave his time to the milking process. Being inhuman and intemperate, he beat the cows, often with cruelty. The customers diminished, and complained that the milk was adulterated with some substance which acted on the bowels. At one time a large number were attacked with diarrhoea and cramps; and many bitter complaints were made. Later the property changed hands, and these troubles disappeared. No complaints of the milk had been made before or after this man engaged in or gave up the business, and it was asserted by a workman who remained during this time that the milk was treated in the same way, and not adulterated, leaving a very plausible inference that the excitement among the cows at the time of milking was the cause of the bad condition of the milk.

These instances seem to indicate that the quality of milk may be chemically and physiologically normal, and yet be poisonous to a large degree, psychologically propagating functional and organic changes of the nervous system as dangerous and positive in their effects as the germs of typhoid-fever through the same source.

Practically, this subject resolves itself into the following conclusions, which should be prominent in the diagnosis of obscure diseases.

1. Milk coming from ill-nourished, half-fed cows, having no surplus of food beyond the minimum requirements of nature, is injurious, and may be the source of disease.
2. Cows deprived of abundance of good water, ventilation, and exercise, secrete impure and dangerous milk, which may be loaded with gases, animalculæ, and fever germs.
3. The milk from old, debilitated cows, fed on grains or overstimulating food, is also imperfect and unhealthy to a variable degree.
4. The nervous condition of the cow at the time of milking determines the purity of the milk. If this be neglected, the milk is an active source of disease, positively dangerous and fatal.
5. Milk adulterated with water is always liable to contain poisonous elements, particularly so in the spring of the year, when all spring and well water is more or less contaminated with surface-drainage. This is the most common adulteration, and probably the most dangerous.
6. Experience has shown that the milk of one cow, unless the exact circumstances and conditions are known, is not superior to the aggregate milk of the whole dairy.
7. Facts show that milk is the prolific source of many diseases now obscure, and unless careful inquiry is made into the condition and surroundings from which we receive our supply, we neglect a sanitary measure of great importance.

PATHOLOGY.

VALLIN ON SYMPTOMATIC MYOCARDITIS AND MYOSITIS IN SEVERE MALARIAL FEVERS.—Vallin communicates the results which he has arrived at on this subject after an experience of two years in Algeria (*L'Union Médicale*, 1874, no. 23). He was induced to examine the voluntary and cardiac muscles by the observations of Zenker, Virchow & Hoffman, Hayem, Desnos and Huchard, on the inflammations which occur in the myocardium and muscles in certain other fevers.

The author thus briefly estimates his own observations:—‘We do not advance another positive opinion; but we are able to say that we have frequently met with a histological alteration of the heart and voluntary muscles very similar to that in other pyrexias. This lesion appears to us to account for certain morbid phenomena in the course of the malady, and ought to contribute in a certain measure to the cause of death.’

In regard to the myocardium in malarial fevers, Vallin refers to its familiar naked-eye characters of flaccidity, yellowish discoloration, and extreme friability, and then sums up the histological alterations. In a first degree are observed absence of striation and transformation of the interfibrillar protoplasm into proteine granules, partly soluble in acetic acid; but this transformation, an acute one, is sudden, and not by any means to be compared with that vague granular condition affecting normal hearts, or indeed a commencing cadaveric disintegration. In a second degree, which frequently coincided with the first, there are fatty transformation of the proteine granules (insoluble henceforth in acetic acid); abnormal accumulation of pigment at the centre of the fibre near the nucleus, especially when the malarial poisoning has been old; increased friability of the granulo-fatty fibres, and real proliferation of the muscle-cells. These lesions always occur in small disseminated foci in the muscular mass. They were unmistakably present in six cases out of ten.

In the voluntary muscles, according to Vallin, the appearances are very different from those just described. In one form the fibres are granular, like those of the heart; the striæ have disappeared, and they re-appear on treatment with acetic acid; the proliferation of the muscular nuclei is active and general, and the nuclei rapidly become granular; and the fibres become unequal, some being swollen and fusiform, and others atrophied. In a second form we meet with all the degrees of the waxy degeneration of Zenker. It is the recti and pyramidales abdominis, the psoas, and the adductores femoris that are the favourite seat of these alterations. Of ten cases examined, the muscles in four had undergone waxy degeneration; in three they were simply granular, in the remaining three they were normal.

As for the symptomatology, it is possible that there may be some connection between these lesions of the voluntary muscles and a condition of excessive muscular debility, with emaciation and dull pains in the limbs, which is frequently observed after an attack of remittent fever. Cases of rupture of the rectus abdominis have been recorded by Cruveilhier and Leubuscher. The alteration of the myocardium ought to cause functional disorders similar to those first described by Stokes in typhus. Vallin found the pulse sometimes very frequent, sometimes exactly the reverse. Several authors have drawn attention to infrequency of the pulse during convalescence from severe malarial fevers, and Vallin asks whether this may not be referable to degeneration of the cardiac muscles, and to the subsequent repair. And some of the cardiac bruits, commonly called anæmic in these cases, may have the same origin. Should this be the case, we may hope to get equally good results from the employment of stimulants—especially alcohol and coffee—in severe malarial fevers as in typhus and typhoid fever.

J. MITCHELL BRUCE, M.D.

FELTZ AND RITTER ON THE ACTION OF CHLORAL ON BLOOD.—In a communication to the Paris

Academy (*Comptes Rendus*, Aug. 3) the authors enunciate the following conclusions from experiments on this subject.

1. A solution of chloral (titrated to a fifth) injected into a dog's veins, causes the death of the animal, if the dose exceed 0.25 grammes per kilogramme. The temperature falls some tenths of a degree, seldom one degree. The respiration, momentarily accelerated, is soon retarded, becomes tetaniform, and stops; and along with these phenomena may be observed a trembling of the respiratory muscles, great paleness of the mucous membrane, some convulsions of the ocular globe, and great dilatation of the pupil. The heart-beats increase in frequency, become irregular, and cease an instant after the respiration. Conscious sensibility disappears before reflex sensibility; the latter is followed by muscular atony. There is no lesion found in the blood or in the viscera; death appears to be due to the action of the chloral on the nervous centre which governs the respiration.

2. The effects produced are different when one injects into the animal only the dose of chloral necessary to anæsthesia, and maintains it in this state by successive injection of fresh quantities whenever the reflex sensibility appears to return. Death occurs after twenty-four or thirty hours at the most. The dose of chloral necessary to maintain anæsthesia continuously diminishes, and the interval of the injections is more and more extended; four or five hours before death all injection becomes useless. The number of inspirations and expirations diminishes slowly and progressively, and is at length reduced to five or six in the minute. The heart-beats are accelerated as the respiration diminishes; the pulse, small, weak, and thready, ceases to be perceived, while the noises of the heart still persist. The arterial tension, indicated by the hæmodynamometer, falls.

The temperature falls only one to six degrees (Cent.) during the first six hours; it rises again rapidly from this point. We have seen it reach seventeen degrees; nearly always death takes place between twenty-four and twenty-eight degrees.

The saliva flows abundantly during the first hours; it becomes exhausted from the time when the temperature and the tension are notably lowered. Urine and dung are excreted from time to time.

The urine contains hæmoglobin in solution, easily recognisable with the spectroscope. The search for colouring matters of the bile, by the most delicate methods, has always led to a negative result. In two cases we have found glucose, which reduced Barreswil's liquor, was rendered brown by potash, and fermented alcoholically with beer-yeast. The urine always remained acid. The red colour of the urine frequently coincides with ecchymotic spots in the digestive mucous. The lungs, the liver, and the kidneys, always hyperæmic, never presented infarctus.

The alterations of the blood are profound; the corpuscles, deformed, have lost their elasticity; the plasma presents a red colour, which increases more and more. The field of the microscope is rapidly covered with crystals of hæmoglobin. We may state that we have never observed the like after section of the pneumogastrics, though this operation brings on some phenomena similar to those which we have observed during chloralisation. The alteration of the blood is further shown from analysis of gases of the blood made at different periods of the chloralisation, and by the capacity of absorption of this liquid for oxygen, with which it is agitated. Without insisting on these various points, we content

ourselves with saying here that the arterial blood of a dog, shaken with oxygen, takes up 250 cubic centimètres per 1,000 before chloralised, and only 175 before death.

3. The toxic action of chloral is sometimes manifested after the waking of the animal, when the chloralised has been prolonged for a dozen hours, and the temperature has fallen to 30° Cent. (86° Fahr.). The alterations of the blood and the urine are then the same as we have described.

The waking of the animal is more rapid, the less the temperature and pressure have been lowered. Reflex and conscious sensibility appear in the first place; it takes two or three hours for the ataxic movements to be regularised.

We have found, in studying the products of respiration, that the greater part of the chloral is exhaled without being transformed. The product of condensation, a little milky, had not the least odour of chloroform, but, it reduced, in heat, an ammoniacal solution of nitrate of silver. This character is common to chloral and to chloroform; but a solution of this latter substance which should produce a reduction to the same degree as our liquid of condensation would have a manifest smell and taste of chloroform. The condensed product further renders green a mixture of bichromate of potassium and sulphuric acid; this character does not belong to chloroform but to chloral. We have been able to assure ourselves, also, of the presence of another organic substance, but the small quantity we have hitherto succeeded in isolating does not allow analysis.

ALEX. B. MACDOWALL.

MEDICINE.

EWALD ON A CASE IN WHICH CARBURETTED HYDROGEN WAS FORMED IN THE HUMAN STOMACH. The following case, communicated to the *Irish Hospital Gazette* by Dr. C. Ewald of Berlin, forms an interesting supplement to Dr. Schultze's paper published in the LONDON MEDICAL RECORD for August 12.

Towards the end of last year, a man presented himself, during the consulting hour of Dr. Frerichs, who declared that he had both a gas and a vinegar manufactory in his stomach. These, he said, worked alternately, so that at one time he brought up quantities of strongly acidulated matter, at another he belched quantities of gas which burnt, when a lighted match was applied to it, with a brilliant flame. In proof of this latter assertion, having twisted a piece of paper into a roll and placed it like a gas-burner in his mouth, he applied at the moment of an eructation a match to its end, when a brilliant bright-yellow flame, fully a foot long, burst forth.

There could be no doubt that we had here to do with a case of abnormal digestion, with the formation of stable and unstable products of fermentation: the question being, what was the nature of the latter. For though the eructation of inflammable gas from the stomach has already been observed, and the gas itself analysed (see the analysis of Carius and Popoff), still the colour of the flame has invariably been a pale-blue, showing the great preponderance of hydrogen; whereas, in this case, the yellow colour of the flame seemed to denote the presence of carburetted hydrogen.

The physical examination of the patient disclosed

a very distended condition of the stomach, to account for which it seemed probable that there was a narrowing of the pylorus, caused by the contraction of a cicatrix of an ordinary round ulcer.

As I have for some time devoted myself to gasometrical analysis, the chemical examination of the solid and gaseous excreta from our patient's stomach was confided by Professor Frerichs to my colleague, Dr. Russtein, and to myself.

The analyses were conducted in the usual manner, the gas being collected over quicksilver by means of a pipe from the patient's mouth, and gave the following volumetric results:

| | 1st analysis. | 2nd analysis. |
|---------------------------------------|---------------|---------------|
| Carbonic acid . . . | 17'40 . . | 20'57 . . |
| Hydrogen . . . | 21'52 . . | 20'57 . . |
| Carburetted hydrogen . . | 2.71 . . | 10'75 . . |
| Oxygen . . . | 11.91 . . | 6'72 . . |
| Nitrogen . . . | 46'44 . . | 41'38 . . |
| With traces of sulphuretted hydrogen. | | |

In some of the matter vomited by the patient some days afterwards, we were able to demonstrate the presence of lactic, butyric, and acetic acids, and some of their homologues (not, however, quantitatively determined), sugar and dextrose.

Under the microscope all the well-known elements of food undergoing fermentation in the stomach were observed, of which I will only mention some very large specimens of *sarcina ventriculi*, the yeast-fungus, and rod-shaped (*stäbchenförmige*) bodies, having the appearance of bacteria (the lactic-acid fungus of Pasteur?).

The irregular decomposition of the contents of the stomach takes, as is well known, one of two ways; either out of the starch, or the sugar it contains, lactic acid is formed, and from this again butyric acid, during which process, according to the chemical formula, equal quantities of carbonic acid gas and hydrogen are given off (the so-called lactic acid or butyric acid fermentation); or, the sugar, during the alcoholic fermentation determined by the yeast, is turned into alcohol, aldehyd, and acetic acid, during which process carbonic acid is given off. The nitrogenous elements seem to take no direct part in this process, but, if there is an insufficiency in the quantity of peptone present, they act indirectly as a ferment to set the process going. These two processes may go on simultaneously, as Budd held (*Diseases of the Stomach*), or the products of one process may remain in the stomach after the fermentation to which they owe their origin is finished, and has given place to the other. The fact observed in this case and other similar ones, that the products of both processes were found in the matter vomited, should not, therefore, surprise us. Similarly we can readily explain the presence of both hydrogen and carbonic acid in the gases ejected, their relative quantities being determined by the preponderance of the one or other fermentation, and the different co-efficient of absorption of the fluid contents of the stomach for each gas. The presence of nitrogen and oxygen is accounted for by all writers on the subject by the presence of atmospheric air swallowed with the food during the act of deglutition. With this view I agree, as in all my analyses the quantities of these gases present corresponded very nearly with their relative amounts in the atmosphere. The large amount of carburetted hydrogen (CH_4) in both cases, the gases analysed being collected at different times, is most striking, while no æthylen (C_2H_4), from 2 to 5 per cent. of which occurs in the flame of common house-gas, could be found.

Carburetted hydrogen or fire-damp (CH_4) has been found in the large intestine by many investigators (Magendie, Chevillot, Leuret, Ruge), so that one could suppose that by a reversed peristaltic action it might be driven backwards into the stomach. In this case there was, however, no such peristaltic action, and in any case I think the way from the colon to the stomach is too long to allow of such a thing being possible. It is much more natural to suppose that this gas is formed in the stomach under conditions similar to those under which it is found in nature, viz., the decomposition of organic matter in presence of a deficiency of oxygen. There was no doubt but that food taken by our patient remained an immense time in the stomach, for he sometimes vomited almost unaltered food swallowed five or six days previously, so that the contents of his stomach were in conditions very favourable for the spontaneous production of carburetted hydrogen.

The next question that presented itself was, whether a similar result would be obtained outside the body. To determine this, a number of glass receivers were filled with matter which had been vomited and allowed to ferment at a temperature of 98°F ; to some of these flesh, starch, and bran-meal were added; others were left without any such addition. The gases given off were found to contain carbonic acid, hydrogen, and nitrogen, but no carburetted hydrogen, which seems to prove that this gas depends for its production on the influence exerted on its contents by the walls of the stomach. Indeed, if we take into consideration the great difference there is between the glass receiver and the stomach as regards equability of temperature, secretion, and re-absorption of the gastric juice, and the circulation of the blood, this negative result will not cause very great astonishment. In any case the undoubted fact that considerable quantities of carburetted hydrogen have been produced in the human stomach is of great interest.

The treatment consisted in regulating carefully the patient's diet, and washing out his stomach by means of the stomach-pump. Under this treatment the discomfort he suffered was greatly lessened, and only once afterwards did he bring up inflammable gas, which, however, burnt with a blue flame. As he soon became quite an expert in introducing the stomach-pump, he has left us, and gone to the country to further recruit his health.

I will now draw attention to a very simple and readily available method of washing out the stomach, which I now always adopt, and which on account of its great simplicity, seems likely to make the topical treatment of diseases of the stomach, especially in cases of poisoning, much more common. A piece of ordinary India-rubber tubing, such as is used for gas-lamps, about six feet long, is used; one end is rounded, with a scissors, and if necessary, two holes are cut at a short distance from the end. This tube possesses quite sufficient rigidity to be passed without difficulty into the stomach. To the outer end a funnel is fitted, into which can be poured either water or a solution of soda, etc., according to circumstances. If the contents of the stomach are to be removed, the outer end of the tube must be sunk to a level of the pubes, or even lower; then the patient must make a short but forcible contraction of the abdominal walls. By this means the tube is filled to its highest point with the fluid contents of the stomach, and becomes a syphon; the liquid continuing to flow until there is no more, or till the tube is stopped up. This

last seldom occurs, if the tube be of a moderate calibre. Should it, however, happen, or should the abdominal pressure be insufficient to fill the tube in the first instance, or the patient be insensible, or any similar difficulty arise, it can, in general, be readily overcome by fitting a common clyster-syringe to the end of the tube, one stroke of the piston of which is generally sufficient to remove the difficulty. This method is evidently instantaneously available, provided that we can find a gas India-rubber tube; and has another great advantage, viz., that with it any mechanical injury to the soft parts is impossible.

In cases where the œsophagus is almost impervious from stricture, compression, or any other cause, I am in the habit of using very thin gum-elastic tubing, made especially for this purpose, within which a very thin piece of whalebone, like the stilet of a catheter, is introduced, in order to give it the necessary rigidity. The whalebone can be withdrawn without difficulty once the tube is passed. Since I have adopted this method, it is only during the first or second introduction of the tube that I have experienced any difficulty arising from the discomfort the operation causes to the patient.

SURGERY.

MCDONNELL ON THE TORSION OF BLOOD-VESSELS.—Dr. Robert McDonnell, surgeon to Dr. Steeven's Hospital, Dublin, has reprinted an article on this subject from Dr. Brown-Séquard's *Archives*. After a few preliminary remarks, and a brief reference to the history of torsion, the author states, 'Since the appearance of Mr. Bryant's memoir on the subject, in the *Medico-Chirurgical Transactions*, 1868, it has been practised by my colleagues and myself in Dr. Steeven's Hospital, Dublin.' He quotes 'with great satisfaction the words of Mr. Colles, as expressing our joint experience. For the last six or seven years, in Steeven's Hospital, my colleagues and I have seldom resorted to any other means of arresting hæmorrhage, even from the largest vessels, and we have never had reason to regret the adoption of the practice.'

After advising any one desirous of making himself expert in the art of torsion to begin by experimenting on the dead subject, he adds, 'It is obvious that torsion is not to be applied to all kinds of vessels in exactly the same manner. Experience teaches us that we must adopt somewhat different expedients in securing by torsion vessels differing in size and position; the greater or less laxity of the tissue which surrounds the vessel, the character of its sheath, etc., all make it necessary to modify somewhat the mode of procedure. The surgeon should have at hand, therefore, several varieties of torsion-forceps, since a pair well suited to twist one vessel may not answer so well for another.'

For vessels about the size of the radial or ulnar, he advocates toothed forceps, such as those generally known as 'Syme's torsion-forceps.' 'The vessel is to be seized right across its open mouth, and drawn out a little; it is then caught just beyond the forceps, between the thumb and forefinger of the left hand, so that the nail of the thumb may give it a good pinch, and nip through the internal tunics; then twist, and all is secure.' [In the reporter's experience, this part of the operation is unnecessary. Some surgeons' nails are anything but clean, and are therefore ill-adapted for such close contact with part of a wound;

and again, some nails are too stumpy to be available for such a proceeding, even if it were a necessary one.—*Ref.*] 'The end may in the case of such vessels be twisted off or not, as the operator pleases.' If the vessels be surrounded with a large quantity of lax areolar tissue, Dr. McDonnell recommends a pair of forceps, one end of which carries three small teeth, to fit between four teeth of the same size on the other end. The procedure consists here, again, of three steps, catching the vessel, nipping it, and torsion. 'Such vessels as the brachial, femoral, or popliteal, are in general very readily secured by torsion;' but in amputations 'in the neighbourhood of diseased structures, sinuses, etc.,' where parts are 'unyielding, it is by no means easy to get space enough beyond the ends of the first or grasping forceps to apply the second or nipping forceps. Under these circumstances, I adopt the following expedient. I place a silk ligature around the vessel immediately beyond the ends of the grasping forceps. This ligature I pull home until it snaps across. To make sure of accomplishing this with some facility, I have the silk fixed on little wooden cylinders, so that it can without hurting one's fingers be pulled home until it snaps across. It invariably snaps close to the knot (half), and is to be pulled off and cast aside. We thus accomplish by a snapped ligature what is done in other cases by the nipping forceps, and then proceed to twist; three or four half turns are sufficient for the femoral, and I always, in this case, leave the end still standing.' This mode, the author states, is very effectual, 'and is applicable to vessels of all sizes which are unmanageable in other ways.' 'In fact, no readier way of securing ordinary-sized arteries can be suggested than to put on, first, a silk ligature, and then to seize the knot in a pair of torsion-forceps, and twist it off. The vessel is perfectly secured, and there is no foreign body left in the wound. Large wounds are often then found healed on the twelfth to the fourteenth day; that is about the time that, in cases where a bundle of ligatures have been left in a wound, these are beginning to separate.' With respect to Dr. Addinell Hewson's forceps, designed to execute the double manœuvre of nipping the coats and grasping the vessel to twist it, Dr. McDonnell states that he has used a pair presented to him by their inventor. He has 'had several opportunities of using them, and found them to do their work satisfactorily on vessels not surrounded with brawny, tough, infiltrated structure. Where, however, this condition exists, or, in fact, wherever there is any difficulty in drawing the vessel out a little from the surrounding structures, Dr. Hewson's forceps are open to the same objection as arises in attempting to use the cross-nipping forceps.' There is not space enough to apply them and to nip properly beyond the ends of the grasping forceps. [Mr. Bryant, in *The Practice of Surgery*, describes only one pair of forceps as necessary for the operation of torsion even on large vessels. The reporter has not been in the habit of employing more than one pair of forceps for the process, which has consisted of seizing, grasping (without nipping), and torsion.—*Ref.*]

JOHN CROFT.

RAVOTH ON THE TREATMENT OF VARICOCELE BY TRUSS-PRESSURE.—Dr. Ravoth (*Berliner Klinische Wochenschrift*, no. 19, 1874) alludes to a former publication on this subject, and states that his recent experiences of the pressure-treatment of varicocele

have been so favourable that he feels compelled to again direct attention to this method, and to recommend its practical application. He has also found the use of a truss useful in cases of varicosity of the leg, and for the relief of distressing irritation of the male genital apparatus, causing excessive pollutions and inducing onanism. With regard to the etiology of varicocele, Dr. Ravoth has not been able to decide whether there be any hereditary tendency to the affection. Its almost universal occurrence on the left side he attributes to the anatomical fact that the left spermatic vein opens at a right angle into the left renal vein, whilst the right spermatic vein opens at an acute angle into the ascending vena cava. He opposes the view that varicocele may be caused by the pressure of a hernia or of a truss, and holds that varicosity of the lower limbs is not due, as it is generally supposed, to such conditions as favour venous stasis. Out of fifteen hundred cases of left-sided inguinal hernia observed by the author, not one instance of well-developed varicocele was found. The main cause of varicocele, according to Dr. Ravoth, is irritation of the male genital apparatus, which is dependent on the development of puberty. This irritation, and not the consequent varicocele, is believed to be the cause of pollutions, onanism, and early and excessive use of the genital organs. Whether the irritation induces dilatation of the spermatic veins by leading to increased flow of blood and relaxation of the cremasteric muscle and the dartos, or whether impairment of the influence of the trophic nerves should be invoked, cannot be determined, the author thinks, without further observation and experimentation. With regard to prognosis, it is stated that varicocele in the majority of cases does never attain any great size, and that patients who do not suffer from pain content themselves with wearing a suspensory bandage. To what extent in the slighter and common forms of varicocele the testicle is impaired in growth, consistency, and function still remains to be strictly determined. Varicocele, when large, is associated with severe pain and excessive irritation of the genital apparatus, which, indeed, according to the author, is the primary cause of the venous enlargement. Dr. Ravoth recommends that the truss be always worn except when the patient is in bed, and that for two or three hours during the day the pressure of the pad be increased by accessory springs. Under the influence of this treatment the varicocele becomes smaller, and any pain from which the patient may have suffered, ceases. These facts can be explained only by acceleration of the circulation in the spermatic veins. At the same time the testicle is drawn upwards towards the external abdominal ring. The author holds that the favourable action of the truss pressure is to be explained by this acceleration of the venous circulation, and in the increase of the impaired irritability and arrest of the morbid irritability of the muscular and elastic structures. Dr. Ravoth objects to surgical operations in cases of varicocele, as he thinks that, like the so-called radical cures of hernia, they often fail and are not free from danger.

Dr. Ravoth asserts that, in some cases of phlebectasis of the saphenous vein, truss-pressure applied to the vein crural, below Poupart's ligament, will produce a cure. Recent cases, however, must be selected, and the surgeon must not expect a very favourable result if the venous enlargement have lasted for many years, and if there be extensive thickening of the walls of the distended veins, and degeneration of the surrounding connective tissue. The wearing of a truss

has been found useful also in cases of morbid irritability of the male genital apparatus. It should be remembered, however, that this irritability will not always be amenable to such treatment, as its conditions are often very complex, and its primary cause may be seated in the gastric or in the uropoietic organs.

THIERSCH ON THE HISTOLOGICAL CHANGES WHICH TAKE PLACE IN THE HEALING OF WOUNDS OF THE INTEGUMENT BY GRANULATION.—Herr Thiersch (*Archiv für Klinische Chirurgie*, Bd. xvii.; *Berliner Klinische Wochenschrift*, no. 29, 1874) was induced by the results of Reverdin's discovery to transplant epidermis, in the case of a man whose leg had been extensively stripped of skin in consequence of a scald. The result was favourable, and the patient left the hospital. He soon returned, however, with as much deficiency of skin as before, and wished for amputation of the leg, which indeed was indicated. The author took advantage of this opportunity for making fresh investigations on the process of healing. Before the removal of the limb he practised fresh transplantation of skin, and thus was able to observe closely in the amputated member the course of the healing, starting from pieces of skin placed on a granulating surface.

The following are the results. 1. The adhesion takes place without the formation of any intervening substance. 2. In the course of eighteen hours there is complete union, through inoculation of the vessels of the granulations and those of the superimposed piece of skin. 3. Not less speedily do the vessels of the transplanted portion of skin undergo a secondary change, through which they more or less assimilate in structure the vessels of the granulations. 4. In many instances the whole thickness of the transplanted skin does not remain fixed, but only the inferior layers, the upper portion being thrown off as a slough. Eighteen hours after the transplantation, the capillaries of the transposed skin may be injected from the granulations. This proves that a vascular connection has taken place. These vessels do not remain intact, but in the course of the third or fourth week return to their former condition. After the fourteenth day epithelium makes its appearance, which the author holds to be the product of the sweat-glands contained in the transplanted portion of skin. The results of Reverdin's method are generally temporary, because the granulating surface cannot be closed, and the natural restorative processes of the organism become exhausted. The injured part having been exposed to the casualties of daily life, the cicatrix breaks down sooner or later. So long as there is no method of applying the portion of skin securely, and the vertical portion of the granulations cannot be removed until a part is exposed which is adapted for union, the result of the transplantation will always be doubtful. It has hitherto been overlooked that blood left on the wounded surface may constitute an obstacle to union. In order to avoid this, the vertical portion of the granulations should be cut away with a sharp knife, and Lister's protective dressing be used. Then no fungus remains, and retraction does not follow.

W. JOHNSON SMITH.

MOLLIÈRE ON THREE REMARKABLE CASES OF DISLOCATION.—M. D. Mollière, of the Hôtel-Dieu, in Lyons, relates (*Lyon Médical*, no. 14) the following cases.

Case 1. *Complete Luxation of the Left Elbow-joint outwards; Reduction.*—This occurred in an idiot, aged forty. The region of the left elbow was swollen, painful, and presented the following appearances. (1) The forearm was flexed upon the arm at an obtuse angle; (2) there was a considerable enlargement of the elbow transversely; (3) the capitellum of the radius was plainly seen beneath the skin, externally; (4) the ulna was not plainly felt, owing to its being hidden by the prominence of the radius; (5) internally was a well-marked eminence, formed by the articular extremity of the humerus, which was readily felt, beneath the integument, in all detail. The anterior aspect of the humerus looked directly *inwards*. Reduction was made, without an anæsthetic, by direct traction and flexion. The bone had been dislocated for three days. The excessive rarity of this accident renders it worthy of record. Nélaton reports one case only in his *Pathologie Externe*.

Case 2. *Dislocation of the Right Femur on to the Dorsum Ilii, of fifty days' standing. Reduction by Pouteau's Method.* A man, aged sixty, fell from a tree, and dislocated the head of the thigh-bone on to the dorsum ilii. On presenting himself at the Hôtel-Dieu, all inflammatory symptoms had disappeared, and the amount of shortening was rendered appreciable by Giraud-Teulon's method of triangles, thus—

| | Sound side. | Injured side. |
|---|-------------|---------------|
| From the anterior superior iliac spine to the ischium . . . | 18'50 | 18'50 |
| From the anterior superior iliac spine to the external condyle of the femur . . . | 47'50 | 44'50 |
| From the ischium to the external condyle of the femur . . . | 40'50 | 40 |

Chloroform being administered, Pouteau's method was first tried without success; and, on breaking up the adhesions direct traction was tried, and failed, and so also did Jarvis' apparatus as modified by Matthieu, both with the limb flexed and extended. A last attempt, however, by Pouteau's method, succeeded, an assistant's hand being placed between the front trochanter and a solid *point d'appui* placed immediately behind it. M. Mollière employed flexion, rotation, and then abduction, and employed considerable force in this latter movement, using a lever, having as its power the shaft of the femur, its fulcrum the trochanter, and weight, the head of the femur. The distinct presence of the head of the femur lying amongst the soft parts, and the inguinal depression being clearly marked, convinced M. Mollière that he might reasonably employ such severe measures for so considerable a time, notwithstanding the patient's age, since the obstacle lay exclusively among the soft parts, and there was no malformation.

Case 3. *Compound Fracture of the Right Tibia and Fibula; Dislocation on the Dorsum Ilii, with severe Contusion of the Trochanteric Region; Injury to the Face; Cerebral and Spinal Complications; Reduction by Pouteau's Method; Recovery.*—The patient was a boy, aged fourteen, who fell from a building. On admission his symptoms were so serious that M. Mollière, believing death imminent, applied a silica bandage, with the view of alleviating his suffering, without further examination, and placed the limb on a Bonnet's splint. He improved by degrees, and, on an examination made on the sixteenth day, a complete dislocation into the dorsum ilii was detected. Ether was administered, and an assistant instructed to follow the movements of M. Mollière by sustaining the fractured limb, which was enveloped in its apparatus.

The process of reduction was commenced, and it was decided not to prolong it for fear of breaking up the uniting fracture, so the assistant placed his hand behind the trochanter, whilst M. Mollière made the flexion, rotation, and forced abduction. The bone entered the cotyloid cavity immediately.

EDWARD BELLAMY.

BERTI ON GASTROTOMY FOR INTERNAL STRANGULATION.—Professor Berti, of the Leghorn Hospital, in a memoir of which an abstract is given in *Lo Sperimentale* for July, describes the case of a man, aged about sixty, the subject of an old right inguinal hernia, which he had always kept up by means of a truss. During a violent effort, he suddenly felt pain in the groin which was the seat of the hernia; and intestinal obstruction, with distension of the abdomen, hiccough, and vomiting of food (but not of faecal matter) set in. From a careful examination of the case, Dr. Berti arrived at the conclusion that the obstruction was caused by a constricting band acting on a part of the bowel not very near the stomach. He accordingly made an incision about four inches long, and laid open the inguinal canal. Here he found a hard mass of omentum, from which proceeded a cord, passing into the abdomen by the internal ring, which guided him to the constricting band. The finger being introduced, this band was divided by means of a knife, and the intestine was set free. The cord was then drawn out and cut off. It was a little time before the bowels recovered their power of acting, and an oleaginous purgative was required, but the patient was quite well in less than a month.

A. HENRY, M.D.

MATERIA MEDICA AND THERAPEUTICS.

FORMENTI ON THE SUBCUTANEOUS INJECTION OF CALOMEL IN PNEUMONIA.—Dr. Achille Formenti, in an article in the *Gazzetta Medica Italiana-Lombardia* of August 8, says that, having observed the good effects of the internal administration of calomel in cases of pneumonia, but having found also that the medicine was not always well borne by the patient, he determined to make trial of subcutaneous injections. In the course of the year, however, he had but few cases of pneumonia; and the number on whom he had had an opportunity of trying the method was very small (six only), in consequence of the repugnance of the country people to anything novel. The patients were males, from twenty-five to fifty years of age; all were of lymphatic and cachectic habit (as is generally the case in the part of Lombardy where he practises), except one young man aged twenty-seven, who was robust and of sanguine temperament. At his first visit, when the patient was in a state of high fever, with burning heat, difficult respiration, dry cough and scanty expectoration, and pain in the chest on the side corresponding to the lung affected, after having established the diagnosis by percussion and auscultation, Dr. Formenti injected into the arm from ten to twenty centigrammes (1 to 3 grains) of calomel in fifteen drops of water, according to the age and the special condition of the patient. He also in some cases applied a few leeches over the seat of pain, as a revulsive; he did not bleed the patients, and gave no medicines internally, but only some refreshing

diuretic drinks. In every case, on his visit next day there was marked improvement both in the general symptoms and in the physical organs, and it seemed to him that the course of the disease was shorter than when the usual treatment was followed. In one patient only, the robust young man already mentioned, there was a relapse at the end of seven days. The injection of one and a half grains of calomel (three grains having been used for the first attack) produced permanent relief. Dr. Formenti did not meet with the production of abscesses or of salivation in any of the cases; and in all, when examined some time afterwards, there was no indication of hepatisation; all breathed as freely as before their illness.

Dr. Formenti says that he will repeat the practice as opportunities are offered, and begs his professional brethren to make trial of the method which he describes; especially the district medical officers, who, as a rule, have the opportunity of seeing cases of pneumonia in an earlier stage, and under less complicated circumstances, than hospital physicians.

A. HENRY, M.D.

ADAMS ON THE INFLUENCE OF ALCOHOL AND TOBACCO ON THE HEART.—Dr. A. Leith Adams, in an article in the *Lancet*, remarks that nowhere can the thoracic sounds be better studied than at a large recruiting dépôt. He says: 'It is indeed curious, as well as interesting and instructive, to note the vagaries in cardiac sounds alone. These, although in no ways so varied as the causes to which they owe their existence, are sufficiently conflicting. Thus, frequently, between exciting and depressing influences of one kind or another, it is very difficult to say how far abnormalities are ascribable to temporary and to organic derangements. Under such circumstances, cases often occur apart altogether from the morbid sounds when the heart's rhythm is perverted. I can give no better definition than a muffling of the two sounds, or what might ordinarily be called 'a variety of irritable heart,' occurring, however, occasionally in subjects not naturally of an excitable temperament. From these persons it was very often readily elicited that they were given to an excessive use of tobacco, either by smoking or chewing, or the two combined, accompanied, in many instances, by drunken habits. The amount of tobacco consumed daily, was ordinarily half an ounce, and often nearly a whole ounce. From constantly observing cases of this description, and invariably associating them with the above causes, I desired several recruits to abstain entirely from tobacco and alcoholic drinks for a week, and return for inspection. In three or four instances out of ten all the symptoms disappeared; whilst in the cases where there was little or no improvement, it was more than probable that the injunctions were not carried out properly. I do not know if this want of clearness in the systolic and diastolic sounds is to be detected in every instance of the excessive use of tobacco or of alcoholic drinks; but judging of the prevalence of the state in question among Londoners (chiefly indoor workmen and persons leading sedentary lives) it would seem to be pretty general.'

A RICHLY ENDOWED HOSPITAL.—From a report recently published by Mr. C. L. St. John on the history and present state of Moldavia, we learn that Jassy, the capital of that principality, contains five hospitals. The largest and richest of them is the hospital of St. Spiridon, of which the revenue is nearly 50,000*l.* per annum.

OPHTHALMOLOGY AND OTOLOGY.

HECKEL ON DEPOSITS OF METALS IN THE CORNEA, AND THEIR TREATMENT BY CHEMICAL REAGENTS.—The *Journal de Thérapeutique*, no. 8, April 25, 1874, contains an article on this subject, which is considered by the author, Dr. Heckel, to have been very insufficiently treated of in our standard works on ophthalmology, although cases where such deposits have taken place are frequently to be seen in our out-patient rooms. The paper contains the results of eight years of study and of practical experiment, which have convinced Dr. Heckel of the value of treatment founded upon chemical reaction. When we bear in mind the treatment of keratitis in ancient times, and the many and various local applications which were indiscriminately employed, it is remarkable that writers in the eighteenth century such as Maître Jean, Anel, Janin, Petit, and Daviel should make no mention of the occurrence of such metallic opacities, which would have been, one would suppose, more frequent than in later times. Later on even Scarpa makes no sign, and, on the contrary, recommends applications of lead and zinc in ulceration of the cornea; and so Wittelen-Benedict (1811), Saunders (1816), Himly and Langenbeck (1818), and Demours and Quadri are all equally silent on the subject. The first mention of the danger of using lead and other metals in affections of the cornea has been ascribed to Weller; but the first formal notice on record is by Mackenzie (1843). From 1830 to 1872, however, so little mention is made of the subject even in the works of our most accomplished surgeons, as to warrant the belief that the occurrence is comparatively a rare one.

Dr. Heckel speaks of two varieties of such deposits;

1. Deposits arising from the prolonged use of nitrate of silver, salts of lead or of zinc, either in solution or in the solid form;

2. Deposits from accidental application of lime and other caustic substances.

Both varieties are to some extent remediable, but by very different treatment. He speaks of the latter variety first, and calls special attention to the writings of Gosselin (*Archives Générales de Médecine*, November, 1855), in which are described the results of the accidental application of caustic lime to the eye, a frequent occurrence amongst bricklayers. Dr. Heckel says that plasterers are exposed to similar dangers from plaster of Paris, and he records an instance which he had met with in 1870. A little of the plaster in powder had been dusted into a man's eye by a comrade, and the entire cornea had at once become opaque. In the case of caustic lime there is said to be formed a genuine eschar, due to the entire destruction of the tissues, the salts of lime becoming actually infiltrated throughout them; with the gypsum, on the other hand, there is merely a combination of the powder with the water within the tissues, and when once it has become sufficiently hydrated the plaster is rendered inert, and does not invade the deeper tissues.

The effect of the two substances was studied by experiments upon the eyes of young animals; and the result of these, and the subsequent examination of microscopical sections, have enabled Dr. Heckel to verify the distinctive actions of the two substances.

The action of gypsum is to combine with the water of tissues, and when once it is saturated, is at an end, causing a limited opacity, and not infiltrating the cells in the deeper layers of the cornea.

The action of caustic is over and above the mere combination with water; the tissue attacked is rendered amorphous, and the deeper layers are infiltrated with, and rendered opaque by, the imbibition of salts of lime.

In neither of these kinds of opacity can any treatment by local applications be of any service.

Opacities occurring, as in class 1., from the deposit of some metallic salt, and, in particular, those of lead or of silver, are more frequently met with, but are limited in extent, and, according to Dr. Heckel, are more within reach of treatment. Under ordinary circumstances they cannot occur without some lesion to the cornea, by which the metal can gain access; and, as the power of the tissues to reduce metals is in proportion to their own thickness and density, so we find that the deeper layers are the chosen seats of these opacities, and thus an albugo or a leucoma is formed rather than a nebula. Dr. Heckel verified these observations by the formation of ulcers, of various depths, artificially produced and injected with solutions of lead. The injection of salts of silver produced similar, but less marked, results.

The opacities caused by deposit of resinous matters would be superficial, of a characteristic red or brown colour, and were even common formerly when it was the custom to use local applications containing balsams of various kinds. The resinous material is not dissolved, and is unable to enter deeply into the tissues.

With regard to treatment, Dr. Heckel complains that our best authors have little or nothing to say; but, as the result of his own experience and experiments, he feels strongly that much benefit may be derived from a prolonged application of reagents. Thus, for the opacities caused by the salts of lead, he recommends the use of solutions of acetate of soda; for those of silver, the hyposulphite of soda. The salts of potassium would answer the same purpose; and the resinous deposits will yield to the frequent application of solutions of alcohol.

GRANDCLEMENT ON PULSATION OF THE RETINAL ARTERIES IN AORTIC DISEASE.—The appearance of pulsation within the retinal veins is well known, but when met with in the arteries it is generally accepted as an indication of disease. Most observers agree with Von Graefe in the belief that its occurrence implies an increase in the intraocular tension. The author of this paper considers this explanation to be by no means complete, inasmuch as the phenomenon has lately been associated with aortic diseases. The first observation to this effect was that of Quincke (1868); and independently, an observation of a similar case was communicated (1871) to the Ophthalmological Congress at Heidelberg, by Otto Becker; and in an article entitled 'The Movement of the Blood Visible in the Human Retina,' and published in the *Berlin Archives* (1872), Becker has recorded seventeen cases of its occurrence with heart-disease. In cases of aortic insufficiency, with or without hypertrophy of the left ventricle, Becker has observed pulsations in the arteries of the optic disc; and in a case of supposed aortic disease in which the pulsation could not be detected, the subsequent necropsy revealed an aneurism of the ascending aorta, with no

disease of the aortic valves ; on the other hand, the occurrence of pulsation enabled Becker to correct a diagnosis of aneurism where there was in fact disease of the aortic valves.

Dr. Grandclement (*Lyon Médical*, June 7, 1874) has been able to verify these observations of Becker, in the case of a young woman aged twenty-seven, who was in the last stage of heart-disease ; the heart's action was feeble and irregular, and its two sounds were almost obscured by a loud double murmur, which was prolonged into the carotids. The phenomena of pulsation were very evident in both the branches of the central artery of the retina ; it should be said, however, that the appearances were rather those of alternate filling and emptying than those of true pulsation, for during the heart's diastole these vessels were reduced to mere threads, and during the systole they regained their usual size and colour. No other intraocular lesion could be detected, and, except of an occasional passing dimness of vision, no complaint was made.

The occurrence of a visible arterial pulsation within the eye when in perfect health, has been noted in some instances by Donders. The observations of Helmholtz do not support the fact of its occurrence, and some experiments made by Becker upon the mesentery of frogs would seem to contraindicate it. In these experiments the action of the heart was seen to produce an acceleration in the movement of the blood, but not an actual pulsation of the blood-vessels ; only when a vessel divided into others of lesser calibre could any pulsation be detected, and, in consequence, Becker asserts that when arterial pulsation is observed in the healthy eye, it is either transmitted from the adjacent veins, or it occurs at the bifurcation of the arterial trunks. He gives, however, no explanation of its occurrence with heart-disease, which Dr. Grandclement thinks can be explained as follows. He supposes that in a state of health the intravascular tension and the intraocular tension are so evenly balanced that no pulsation or alteration in the size of the arteries can be detected ; when, however, the harmony between these is disturbed, either by the increase in the one, or by the depression of the other, the phenomena of pulse are at once apparent. Thus when the intraocular tension is increased, as in glaucoma, the calibre of the arteries during the heart's diastole is considerably reduced, and during the systole is again restored ; by reversing the order of things, and supposing the intraocular tension to be normal, and the intravascular tension to be depressed, as in the later stages of aortic disease, the same appearance of pulsation would be noticed.

The explanation, then, of the pulsation of the retinal vessels in glaucoma and in cardiac disease, consists in the want of harmony between the intraocular tension and the intravascular tension in the arteries upon the optic disc. In the same way Dr. Grandclement explains that a retinal pulse should occur in cases of rapid and abundant hæmorrhage.

BOWATER J. VERNON.

LE FORT ON THE APPLICATION OF THE CONTINUOUS CURRENT, WEAK AND PERMANENT, TO THE CURE OF OPACITIES IN THE CORPUS VITREUM.—In *L'Union Médicale* for July 9, 1874, Dr. Léon Le Fort relates the results of his treatment of opacities of the vitreous humour by the continuous current. In one case, where the patient had been blind in one eye for several years, and in the other for several months, on account of opacities

of the vitreous body, about six weeks' treatment completely re-established vision. In a case of optic neuritis, treated at the end of last year by M. Le Fort with little benefit, and in which, after leaving the hospital, the vision became so weak that the patient could scarcely determine the position of the window, the application of the rheophores, one on each temple, of a current of two small elements of Morin, enabled the patient in three weeks to write a letter, in six weeks to thread a needle easily, and completely re-established his sight. M. Le Fort is applying the same treatment to cataract and atrophy of the optic nerve, but, as his experience is too recent, he cannot yet give results.

W. LAIDLAW PURVES.

MISCELLANY.

RABIES MEPHITICA.—The Rev. C. Harvey, in a paper under this title published in the *American Journal of Science*, describes the bite of the skunk as nearly always fatal, from the character of its salivary secretion, which is poisonous, either from the effects of a common disease, or in its normal state. The author says that the skunk is much dreaded in the Western States, as it is a nocturnal animal, and bites without warning.

CREMATION IN EARNEST.—The municipality of Vienna has, by advice of the Board of Health of the city, decided that the cremation of the dead should be immediately carried into operation on the same plan which has been completely successful in Leipzig. As the annual mortality of Vienna amounts to about 20,000, the public authorities reckon on making a great saving as well as a considerable benefit to the public health.

A GREAT PRIZE.—The French Government has practically testified to the importance they attach to the eradication of that insect plague, the phylloxera, by offering a prize of 300,000 francs (12,000*l.*) to the inventor of an efficacious method for its destruction, or for the prevention of its ravages. A commission to be named by the Minister of Agriculture will determine the conditions on which the prize is to be awarded, and decide if any of the methods proposed are worthy of the reward offered.

THE FIRST JAPANESE M.D.—Susum Sato, son to the private physician of the Mikado of Japan, has lately received his M.D. degree at the University of Berlin. Our Japanese *confère* passed a very creditable examination, read a dissertation on diarrhoea in young children, and sustained his various theses with great ability, and in very good German. He then addressed the usual application in Latin to the authorities for his doctor's degree, which was duly conferred on him after some compliments from the Dean on the circumstance of his being the first of his countrymen admitted to this distinction.

THE INFLUENCE OF POLITICAL AND SOCIAL DISTURBANCES ON MENTAL DISEASE.—Dr. Lunier, Inspector-General of the French Lunacy Department, has recently published the results he has obtained from a careful study of all the statistical documents he has been able to collect on insanity in France during the years from 1869 to 1872. He has arrived at the conclusion that although during that trying period for Frenchmen from 13,000 to 14,000 cases of mental disease were registered, yet the number of patients confined in private asylums was much below the usual average. A similar fact was observed in 1848, which, taken in connection with the state of things observed by Dr. Lunier, would make it appear that political or social crises, instead of, as is generally imagined, augmenting the number of insane persons, really diminishes it.

MODERN PATRIARCHS.—The *Allgemeine Medicinische Central-Zeitung* reports the death, at Exin, of Madame Klausner, widow of a rabbi, in the 110th year of her age. Her husband, at the time of his death in 1861, was more than 100 years old.

UNIVERSITY OF VIENNA.—The total number of matriculated students in the University of Vienna during the year 1873-4 was 7,526; of whom 1,109 were medical students in the winter session, and 1,036 in the summer session. The number of new entries in the medical department was 194. Among the largest medical classes were those of Professors Brücke (885); Hyrtl (680); Bamberger (540); Billroth (509); Dumreicher (495); Rokitsansky (354).

A SCIENTIFIC PRACTICAL JOKE.—In a little work entitled *Recuerdos de Humboldt* (Recollections of Humboldt), the author, Dr. Aristides Rogas, relates what he terms *un incidente gracioso*, which happened to Humboldt at Calabogo. On approaching the llanos he was very anxious to obtain information about the electrical eels (*tembladores*) which abound in the rivers of the district. For this purpose he arranged to visit an eccentric student of electrical science, who before the appointed time contrived with some ingenuity and great difficulty to place one of the animals in question *en rapport* with the knocker on his study door. The servant, as desired by his master, directed the illustrious visitor to rap, and on his doing so a discharge of electricity took place throwing him to the ground. The narrator goes on to state that Humboldt received this practical information as to the nature and amount of the electricity generated by the *tembladores* with all the equanimity of a philosopher in search of knowledge.

ST. ANDREWS' MEDICAL GRADUATES' ASSOCIATION. The committee appointed at the last meeting of the members held December 30, 1873, met on Friday, July 31. Dr. B. Ward Richardson in the chair. The treasurer (Dr. Paul) reported that after payment of the working expenses and the cost of the transactions, there still remained a balance in his hands of 60*l.* 1*4s.* 1*d.*, although 78 members had not yet paid their subscriptions. It was resolved:—1. That a sum of twenty-seven pounds be voted out of the surplus for the 'Mrs. Day' fund. 2. That a sum of ten guineas be applied out of the surplus to give a trifling recognition to Dr. Paul for his valuable services as treasurer during the existence of the Association. 3. That the balance of the surplus be placed in deposit in the names of Drs. Richardson and Paul, to meet any future contingencies arising in connection with the University Committee of the Association. It was also resolved that the subscriptions at present unpaid should be forwarded to Dr. Paul for the same purpose.

A VICTIM TO DUTY.—Advices from Tripoli contain details of the death of Dr. Laval, staff-surgeon in the French army, who has recently fallen a victim to his disinterested labours during the late outbreak of plague at Benghazi. It appears that M. Laval had taken advantage of a furlough to devote himself to scientific researches in the regency of Tripoli. Hearing that the plague had broken out in the environs of Benghazi, he immediately hastened to that locality, where finding himself the only medical man, and the only European on the spot, he in co-operation with the local authorities, promptly adopted measures to check the progress of the epidemic; at the same time devoting his utmost energies to the care and treatment of the plague-stricken peasants. His unbounded devotion to his self-imposed duties unfortunately proved fatal to him. Attacked by the disorder he was attempting to combat, he succumbed to its effects with manly resignation after six days' illness. The death of M. Laval naturally produced a profound impression of sorrow amongst the people whom he was so nobly trying to serve; the whole population of Benghazi, wishing to testify their regard for his memory,

were present at his obsequies, which were celebrated with well-deserved solemnity in the Catholic church of the place.

CONTAMINATION OF AERATED WATERS.—The case of lead-poisoning by soda-water, reported this week by Dr. Wilson of Campsie, which has attracted public attention, has a close parallel in the results reported a few months ago by an eminent London hospital physician in the *British Medical Journal*. In that case also, the examination of a number of specimens of aerated water, in the laboratory of Messrs. Savory and Moore, proved them to be all dangerous to health. These waters were sold in syphon-bottles, in which the danger of metallic poisoning (from the avidity with which alkaline waters charged with free carbonic acid will attack metal) is much greater than in the case of waters sold in ordinary glass bottles. There is, however, a much greater and more common danger in the artificial aerated waters of commerce than that of metallic poisoning. Chemical examination has proved what the palate, though without discovering the reason, will often detect; that a great number of these waters are made with well-water which is highly contaminated with organic matter—in fact, laden with sewage. It is not very uncommon, on opening a bottle of soda or seltzer-water which has been kept long, to find that it positively stinks, and a very perceptible flavour of sewage is quite common in these bottled artificial waters. The whole subject was investigated a few years ago by the medical paper which we have already mentioned; and the result of the chemical examination was to show, first, that what is sold as soda-water is commonly, in fact, generally, not soda-water at all, or in any way alkaline or antacid, but gaseous water; and secondly, that the average purity of the water itself was considerably less than that of London drinking water, and that some of the samples purchased and examined were excessively foul, in truth, little better than aerated ditch-water.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 1*7s.* 4*d.*; free by post, 1*9s.* 6*d.*

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2*s.* 6*d.* each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & CO., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 1*9s.* 6*d.* Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1*s.* 6*d.* each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & CO.—Calcutta: THACKER, SPINK & CO.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & CO.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & CO., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, SEPTEMBER 2, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

THE PROGRESS OF BIOLOGY. By PROFESSOR REDFERN, M.D.*

I consented to allow myself to be nominated President of this Section in compliance with the kindly expressed wishes of scientific friends, notwithstanding that I felt that the duties of the chair would have been more fitly discharged by many who have attended the meetings of the Association more regularly, and laboured to promote its objects more continuously than I have been able to do.

Fortunately, the increasing importance and the vast extent of the subjects comprised under the head of Biology have led to a division of the business of this section into the separate departments of Anatomy and Physiology, Botany and Zoology, and Anthropology; and it is a great relief to me that the departments of Botany and Zoology, and of Anthropology, respectively, will be presided over by gentlemen of the highest eminence in those subjects, and that anatomy and physiology, in which I am more immediately interested, will alone come under my direct supervision. It has occurred to me that, in attempting to give a stronger impulse and a more systematic direction to scientific inquiry, the time ordinarily devoted to an introductory address could not be more profitably occupied than by bringing into as great prominence as possible some of the great revolutions in our knowledge of anatomy and physiology which have taken place in my own time and under my own immediate observation.

I remember, as if it were yesterday, the elucidation in the Museum of the Royal College of Surgeons of Edinburgh, of the newly discovered cell-theory, by the late distinguished Professor of Anatomy in Edinburgh, John Goodsir—his account of the production of ulceration by cell-growth, of the characters of the corpuscles of bone, of the structure of lymphatic glands, and of the germinal centres of basement-membranes as they were then understood. This was the time when the teaching of histology was first established in Great Britain. Two students, of whom I was one, formed the first class under the most enthusiastic of teachers, my old friend, Dr. Hughes Bennett. The University of Edinburgh had just passed through what was probably the most brilliant period in its history. The race of the last of the Monros was well-nigh run; the great discoverer of the difference between the motor and sensory nerves, Sir Charles Bell, was still living; the aristocracy of Scotland had only just ceased to crowd the class-rooms and witness the brilliant and successful

experiments of Dr. Hope. The day of Cullen, of Home, and Duncan, and Macintosh was over; but there still remained in the University the most loved and revered of teachers, the benevolent Dr. Alison, Sir Robert Christison, Sir George Ballingall, and Mr. Syme. Dr. Abercrombie was still practising his profession in the city.

At this period the great discoveries of Schleiden and Schwann seemed likely to upset all that had previously constituted physiology. The idea that all tissues were either composed of cells or had been formed of cells—that nucleated cells elaborated all the secretions and formed the excretions—that their energy lay at the very root of the formation, the reproduction, and the function of every tissue and organ, was a revelation of such astounding simplicity as might well upset men's minds and prevent their seeing beyond.

No one, who did not live through that time, will, I believe, ever realise the eagerness and anxiety with which every new statement of the action of cells was received and added to the previous knowledge of their amazing power, or, on the other hand, be able to judge of the feeling, half akin to disappointment, which was experienced as each succeeding attack was made on this charming theory, showing it to be really human, very human indeed.

Cells were then understood to constitute the mass of all organs (the liver, spleen, kidney, and brain), and to be the main agents in the discharge of their functions—to exist and grow upon the definite membranous walls of the glandular vesicles and ducts—to be fed by blood brought to the attached surface of membranes, which seemed almost everywhere to form an absolute separation of the cellular part (the potential gland) from the non-essential blood- and lymph-vessels, the nerves, and framework of the organ. It seemed almost a pity that these little microscopic deities should be hampered by the necessities of their own existence, that they should need such base things as blood-vessels, nerves, and packing materials. Now how strangely are matters changed! What if it should turn out that these apparently independent little beings are not independent at all—that they are only the dilated ending of nerves? To this subject I shall refer again by-and-by.

This great cell-theory has now given place to what I think is certain knowledge, that living matter may move, perform all the functions of assimilation and nutrition, and reproduce its like without having any of the essential characters of a cell. A living mass of protoplasm may change its shape, alter its position, feed and nourish itself, and form other matter having the same properties as it has, and yet be perfectly devoid of any structure recognisable by the highest powers of the microscope.

Mr. Lister showed that the contraction of pigment-cells in the skin changes the position of the pigment-granules, driving them alternately into the processes and the body of the cell. Kühne, Golubew, and Stricker observed changes of form in amœbæ, white blood-corpuscles, and embryonal capillaries, respectively, after the application of electrical stimuli; and Brücke observed contraction in the pigment-cells of the skin of the chameleon after excitation of the sensory nerves; while Kühne noticed contraction in corneal cells after excitation of the corneal nerves.

Thus obvious movements in fixed cells or masses of protoplasm are proved to result from the operation of various stimuli, including nervous stimuli.

* Being the Opening Address in the Section of Biology delivered at the Annual Meeting of the British Association, 1874.

But all cells are not fixed. The blood-cells, fixed as cells of organs at an early period, become free in the blood-fluid and are moved along by the forces which circulate it, until a second time they enter into the composition of the solid tissues by penetrating the walls of the blood-vessels and moving along the substance of the tissues, for purposes which are not yet wholly explicable.

What naturalist will not at once suggest how frequently this process of alternate fixation and movement of animal forms occurs low down in the scale? and yet how startling is it in man! how impossible to reconcile with our former ideas of the existence of membranous coverings, of cells, surfaces, and of gland-ducts! But, with or without explanation, the facts must be recognised; the floating blood-cells are really the very cells which once formed the substance of the lymphatic glands, the spleen, and other organs; and they do, in fact, move through the walls of the blood-passages, and wander about freely in what we call solid tissues.

Our knowledge of this circulating fluid has marvellously increased. The duration of the life of any of its particles is but short; they die, and their places are occupied by others, as was the case with our forefathers, and will be the case with ourselves. It is now a matter of observation, which commenced with Hirt of Zittau, that after every meal an amazing number of white corpuscles are added to the blood: breakfast doubles their proportion to the coloured corpuscles in half an hour; supper increases their proportion three times; and dinner makes it four times as great. They come from such solid glands as the spleen. In the blood going to the spleen, their proportion is one to two thousand two hundred and sixty; in that returning from the spleen, it is one to sixty. Every organ and every tissue changes this fluid; and, to my mind, perhaps the most stupendous miracle of organisation is the steady maintenance of but slightly variable characters in the living and moving blood which is every moment undergoing changes of different kinds as it circulates through each tissue and organ in the body.

Yet with all this change there is an invariable transmission of the parental characters by continual descent from particle to particle as each takes the place of a former one; and thus each organ continues to discharge the same function from year to year. Animals of the same kind retain the old number of organs, the same shape of body, and similar modes of life. There is no sign of commencing life, no coining of new vital power, no production of living out of dead matter. The original life extends its limits; it operates in a more extended sphere; but it is the same life, it operates in the same way, it never fails to be recognisable in the individual by the same characters as it had when it was first known. Whatever other functions it discharges, it acts continually in obedience to the first great law; it increases and multiplies, and replenishes the earth.

Let us now for a few moments compare our former views of the structure of animal membranes with the present ones. The skin (covering the outer surface of the body), the mucous membranes, the serous linings of the great internal cavities and of the blood- and lymph-vessels, and the lining membranes of joints, were all alike viewed as if formed of a definite membrane covered on one side by cells, and on the other supplied by blood- and lymph-vessels and by nerves—the membrane covering in the latter parts

and effecting an absolute separation of the cells from the vessels and nerves, which were universally believed never to penetrate into the cellular layer. The cells were regarded as the parts actively engaged in the performance of the functions, the vessels and nerves aiding thereto supplying materials to be acted on by the cells, and the nerves regulating the amount of action at particular times for special purposes. The diseased conditions, like the functions, were kept perfectly distinct; and we had one set of diseases of the epithelial or cellular parts, and another and a different set of diseases of the membranes and of the parts below.

I think the first occasion on which the public faith in these views was seriously shaken was when the late distinguished Professor of Medicine in St. Andrew's, Dr. John Reid, died of what was called an epithelial cancer of the tongue. Microscopical examinations showed that the disease existed in the cellular covering of the tongue. A sufficient cause for it was supposed to exist in the irritation caused by sharp points of the teeth, to cover which a protecting silver plate was constructed. The diseased parts were removed with the greatest skill and care by Sir William Fergusson, and subsequently by the late Dr. James Duncan, assisted by Mr. Goodsir and Mr. Spence, now Professor of Surgery in the University of Edinburgh. Every conceivable care was taken by these attached friends of the poor sufferer to remove every trace of the disease; but it progressed steadily, and destroyed his valuable life.

At this period no one could understand the extension of an epithelial disease through a basement-membrane; and therefore the affection of the adjacent lymphatic glands was explained by supposing the diseased action to have been propagated from cell to cell along the epithelial surface of the lymphatic vessels.

Not long afterwards the sternly truthful and accurate Sir James Paget declared, in terms of terrible significance, to the sufferers from this disease, that epithelial cancer takes a little longer time than ordinary cancer to do its fatal work.

And it soon became thoroughly well known that the glands of the skin, the hair-bulbs, and the teeth, are produced by a local development of the deep cells of the cuticle, extending far below the line of the basement-membrane or cutis, and through the position which it was supposed to occupy, as though no membrane were there to hinder them.

Thus the basement-membrane, which was supposed so arbitrarily to separate the cells on one surface of membranes from the vessels and nerves on the other, gives way at once before an increased development of the cells, whether in the formation of new organs or in the extension of disease. And the membranous walls of capillary blood-vessels allow the corpuscles of the blood to pass through them, much in the same way as solid particles enter into and traverse the substance of the protoplasm of an amœba or other mass of sarcode.

Whilst physiologists were engaged in these observations, the late Master of the Mint, Mr. Graham, was conducting a series of experiments of the most remarkable kind, and of the utmost importance to physiology as well as to chemistry and physics. He found it necessary to separate the two sets of substances as crystalloids and colloids—the colloids being penetrable by the crystalloids as readily as water, the crystalloids (such as hydrochloric acid and common salt) passing through organic membranes

with great freedom, whilst many of the colloids, such as albumen and gum, will not penetrate them at all. This discovery has enabled the chemist to separate crystalloids from colloids by dialysis, even when they occur in the most minute proportions—for instance, to separate 80 or 90 per cent. of a ten-thousandth part of arsenious acid in twenty-four hours from porter, milk, or infusions of viscera, substances notoriously difficult to analyse. And it has enabled physiologists to explain how animal membranes are traversed by various substances which could not pass through them without being changed from the colloidal into the crystalloidal form. Thus the colloidal starch and albumen of our food scarcely admit of absorption, until in the process of digestion the starch becomes sugar, and the albumen albuminose, crystalloidal bodies which pass through animal membranes with great facility. And again, this crystalloidal albuminose, after having passed into the tissues through the membranous walls of the vessels, may become a second time a colloid, and be deposited and fixed as tissue-substance, ready in its turn to be permeated by crystalloids either for temporary or more durable purposes in the economy.

The effect of this great discovery of Mr. Graham's shows how impossible is the advance of physiology, without a corresponding advance in our knowledge of chemistry and physics.

If basement-membranes, the walls of blood-vessels and of cells are made up of colloidal matter, we can easily understand how they are penetrated by crystalloids; and in like manner it is perfectly possible that they may be traversed by other substances in solid forms—as, for instance, the walls of blood-vessels by the corpuscles of the blood. No wonder that there is a continual deposition and removal of the constituents of the tissues, if so slight a change as that from the crystalloidal to the colloidal form, and the reverse, makes such perfectly marvellous differences in the relations of these substances to each other.

We must look upon the tissues of an animal body as we do upon the substance of an amoeba, and re-collect how penetrable the surfaces and tissues of animals are; then we shall cease to be startled when we see these parts become the seat of entirely new deposits, or find them traversed by migrating blood-corpuscles as freely as a colloid is penetrated by a crystalloid.

It is impossible to foresee what may be the result to physiology of this great advance in our knowledge of the varying relations of substances to each other according as they present themselves at different times in the opposite physical conditions which were described by Mr. Graham as crystalloidal and colloidal. But it is plain that we cannot continue to look upon animal membranes as forming such decided barriers against the penetration of one tissue by another, or by foreign matters, as was once supposed.

Let me now direct your attention to the present aspect of the question, how far basement-membranes limit the distribution of vessels and nerves, and separate them from the cells of glands and membranes.

Mr. Bowman, in his admirable researches into the anatomy of the organs of sense, discovered that the filaments of the nerves of smell have a remarkable structure—that they are nucleated, finely granular, contain no white substance of Schwann, and resemble the gelatinous nerve-fibres. The epithelial surface, too, of the olfactory region Mr. Bowman described as differ-

ing greatly from that of the adjacent parts of the nasal mucous membrane, and as being of a dark sepia tint. Subsequent examinations by Hoyer, Max Schultze, and Lockhart Clarke, confirmed these statements; and those of Schultze demonstrated that the cells are of two kinds, one elongated and filled with yellowish granular protoplasm, exposed at the outer end of each cell and containing a clear oval nucleus in clear protoplasm in its deeper part, which is first attenuated and then expanded into a broad flattened process, apparently connected with the connective tissue; the other cell, the proper olfactory cell, a thin, fibrous, rod-like body, is moniliform or varicose, connected below with the outrunners of a nerve-cell, and in birds and amphibia furnished with one or more hair-like processes, which at the free end come directly into contact with odorous particles. Exner in 1872 denied the distinctness of these two forms of cells, stating that there are all intermediate forms, and that both forms are connected with a deep network continuous with filaments of the olfactory nerve. But Dr. Newell Martin, in a paper published in the November number of the *Journal of Anatomy and Physiology*, maintains that the two kinds of cell are distinct, though their characters approximate very closely in the instance of the frog. He inclines to the belief that, as both forms of cell are so distinct from ordinary epithelium, they are all olfactory cells.

The only conclusion which can be drawn from these observations is, that in this situation the olfactory nerves divide into myriads of small finger-like processes, which, exposed on the free surface of the membrane, are actually engaged in feeling at the odorous particles to inform us of their characters.

This single instance, so thoroughly proved, would be sufficient to destroy our former ideas, that nerves are spread out under basement membranes and never penetrate an epithelial layer.

But this is not the only case of the kind. The general relation of the gustatory nerves to the epithelial cells of the tongue has been described by Axel Key as similar in the fungiform papillæ of the frog, and by Schwalbe and Lovén in the gustatory cells of the circumvallate and of some of the fungiform papillæ in men and animals. On the protected sides of the circumvallate papillæ a peculiarity in the shape and arrangement of the epithelial cells produces a series of taste-cones, the central cells of which are furnished with hair-like prolongations similar to those of the olfactory cells.

In the otolith-sacs and the ampullæ of the semi-circular canals of the ear, the nerve-filaments, having lost their white substance, become connected with peculiar auditory cells and end in hair-like processes between the epithelial cells. In the cochlea, too, notwithstanding the complication of the examination produced by the rods of Corti, there is reason to believe that the cells supporting hairs which project beyond the epithelial surface are connected with the primitive nerve-fibrils of the plexus below.

Of the recorded instances in which nerves pass through basement-membranes to get into direct contact or continuity with the superjacent epithelial cells, none is so striking as that of the salivary and other glands, if there be the least ground for the remarkably detailed observations and suggestions of Pflüger. They are of so much importance and interest in connection with the whole process of secretion, that I offer no excuse for directing your attention to them, even though it may be proved that

the act of secretion is not attended with such marvellous and extensive changes of structure as Pflüger supposes. Up to a certain point, his observations may be easily and abundantly confirmed; beyond that, there is much greater difficulty; but this meeting offers one of the most favourable opportunities for extending our knowledge, by bringing different observers into easy communication with each other, and enabling each to help the rest by stating the means by which he had overcome what seemed at first to be insuperable difficulties in the progress of an investigation.

Pflüger calls attention to the very variable characters of the alveoli, the secreting cells, and the excretory ducts of the salivary glands. These parts, which were believed to have very determinate sizes and characters, he declares to differ very greatly in different parts of the same gland. The alveoli, occupied by what we understand as secreting or glandular epithelial cells, and the excretory ducts lined by columnar epithelium, he thinks he can prove to be but different stages of development of the same structures, produced on the ends of the myriad nervous filaments supplied to these glands.

On this view, glandular epithelial cells must be regarded as special organs of termination of nerve-fibrils, like the auditory cells, touch-corpuscles, olfactory cells, muscular fibre-cells, and the like; the relation between such structures and the nerves becoming so close that it may be difficult, perhaps impossible, to define their respective limits. Pflüger has figured the nuclei of the cells of the alveoli of the salivary glands, the salivary cells, connected with a delicate fibre, which often pierces the surface of the cell in contact with the *membrana propria*, and gives the cell the appearance of being stalked. This appearance has also been seen by Schlüter, Otto Weber, Gianuzzi, Boll, and Kölliker; and indeed the appearance which Pflüger has figured may be seen by any one who will take the trouble to examine the salivary glands of the common cockroach (*Blatta orientalis*). This process was shown to me by my friend and pupil, Mr. Charles Workman; and I have several preparations which show a similar process to that which Pflüger has observed and figured; but that it is as clearly connected with the nucleus of the cell as he describes it, I am not prepared to affirm. Pflüger says it is hollow, and often discharges a large quantity of tenacious material which clearly proceeds from the nucleus.

In the interior of the gland there are ducts lined with a thick but single layer of columnar epithelium, the cells of which are clear and nucleated near their free end, but furnished with a large number of extremely fine varicose hairs at the end connected with the *membrana propria*. This epithelium becomes thicker as the ducts proceed towards their connection with the alveoli; and as transparent drops can be seen transuding from the ends of the cells when saliva has been made to flow by irritation of the gland, Pflüger concludes that they are important secretory organs. Such ducts frequently form loops, or bend suddenly, or possess diverticula. The epithelium of the ducts, which carry the secretion out of the gland, is of a different and apparently less important kind.

Pflüger directs special attention to the great number of nerves connected with the alveoli. He has identified them in fresh specimens by their investment here and there by an ordinary double-contoured medulla, by their being blackened by perosmic acid,

by their varicosities, and by tracing them to large and more easily recognisable nerves. He finds them branching in great numbers amongst the cells of the alveoli, and traces their fibrils to the nuclei of the cells, sometimes after they have been connected with multipolar ganglion-cells. Or nerves covered by medulla and sheath, and containing numerous varicose axis-cylinders, branch, enlarge, and become covered with protoplasm set with nuclei, forming what Pflüger calls a protoplasmic foot, and supposes to be a structure intermediate in character between nervous and glandular tissue. And on the surface of the ducts lined by columnar epithelium a nerve divides into a pencil-like tuft of varicose fibrils, each of which Pflüger says is directly continuous with one of the processes of a columnar epithelial cell. I have frequently seen the pencil-like tuft of varicose fibrils on the surface of the ducts lined by columnar epithelium; but it is not so easy to be sure that the fibrils are connected with the processes of the cells. However, the statement is made in the most positive way by Pflüger, who has made these glands the subjects of very special and lengthened investigation; and his drawings afford very strong corroborative testimony of the value of his statements. Moreover, in independent observations on the pancreas, he has also traced the nerves to endings in the secreting cells.

But Pflüger has gone greatly further than this. He has figured the hair-like processes at the attached end of the columnar cells in all stages of transition into salivary cells of new alveoli; and having previously found the nerves connected by varicose fibrils with protoplasmic masses set with nuclei, he concludes that it is possible that the salivary cells are developed on the ends of the nerves without interference of their own nuclei, and that, as a continual new formation of alveoli and salivary cells implies the atrophy and disintegration of corresponding older parts, the alveoli with pale offshoots of various forms which he has seen in moles are evidence of such atrophy.

With these numerous instances in which nerves are alleged to pass through membranes to be connected with the cells on their surfaces, as if these were their special modes of termination, we might well be content until there has been time for further investigation by independent observers. But there are yet other instances. Langerhans described, in 1868, a fine network of fibres in the skin, from the superficial part of which fine non-medullated fibres pass out of the cutis and end in the Malpighian layer of the epidermis. He saw in the epidermis also well-marked cells which gave off several processes towards the horny layer, and one long slender process which passed through the Malpighian layer into the cutis. He considers these cells to be nervous, and their peripheral processes to be the terminal parts of the nerves of the skin. C. J. Eberth agrees in the main with Langerhans, and recognises fine nerve-fibres passing from the nerves of the cutis into the deeper layer of cuticular cells, and also star- and spindle-shaped cells in the cuticle, which he suggests may be nervous structures, though he has not traced them in connection with nerve-fibres.

On the surface of young fishes and Amphibia, F. E. Schütze has described nerve-hairs arranged in the form of tufts or brushes, very much as in the case in the organ of hearing; in this instance the brush-like endings of the nerves are probably connected with touch.

Cohnheim has described the corneal nerves as forming a superficial plexus under the anterior elastic lamina; from this perforating branches pass perpendicularly through the lamina, and then under the epithelium, break up into brush-like or star-shaped finer branches, which form a plexus giving off fine nerves at tolerably regular intervals between the deep columnar cells and the more superficial spheroidal ones, and dividing at length into their finest branches, which end by somewhat swollen extremities in the most superficial epithelial layers. Thus the exquisite sensibility of the front of the eye, like that of the olfactory or gustatory mucous membranes, may be accounted for.

When I look upon the vast amount of research which has been applied to this department of biology for some years past, and think that the instrument which has afforded the great means for it was only perfected so as to be capable of use for such purposes about 1820, I cannot but congratulate the Section on the abundant fruits we are reaping.

And when, in addition, I contemplate the amount of certainty which physical science has imparted to physiology by furnishing the means of examining and accurately measuring the rates of transmission of nerve-currents, of obtaining tracings of the respiratory movements and of the arterial pulsations, of examining the retina in the living eye and the larynx of a living man almost as readily as if these parts were exposed in a dissection, I cannot but conclude that this nineteenth century has already been distinguished as a very notable one for biology, and especially for physiology.

Considering that so much time is required for making a single careful observation, it is very fortunate that so large an array of inquirers and so much talent are employed upon the subjects in which we are interested, and that once a year we have this admirable opportunity of listening to the results of inquiries instituted by the most eminent men in all parts of the world, and of hearing different views advocated with the greatest earnestness and yet with perfect good humour, and a rigorous determination to rest satisfied with nothing but the truth.

RABIES AND HYDROPHOBIA—THEIR CURABILITY.

Taking for his text the epigrammatic sentence:—‘There is no disease so slight but that it may cause death, and there is no disease so serious as to be incapable of cure,’ M. Decroix, in a pamphlet of forty pages, urges that it is an error to call hydrophobia incurable. He refers to seven cases of recovery, some from rabies in the dog, others from hydrophobia in man. Unfortunately, with one exception, the cases are ill-observed and loosely reported. The exception is that of a dog carefully inoculated for experimental purposes, which in due time developed characteristic symptoms, but, to the surprise of the experimenter, recovered. Now, we do not affirm that a rabid animal or a hydrophobic man never can recover or never has been cured, but we do say that the infinitesimal proportion of recoveries recorded justifies the disease being looked upon as incurable.

We cannot accept M. Decroix’s conclusions, that ‘rabies is not such a terrible disease as the public seems to think,’ or that ‘the hopeless theory of incurability is upset by well authenticated cases of

recovery.’ Recent experience in this country and in America points to directly opposite conclusions. M. Decroix would probably reply that the cases were not properly treated. He says that ‘the rational method of treatment should follow two indications—to remove the patient from all causes of excitement and to procure them all the material and moral comforts compatible with their condition;’ and he adds, ‘that by adopting this method we obtain a “natural rabies,” more amenable than the “artificial rabies,” due to heroic remedies, and that cases of recovery are greater than under the old system.’ Our experience does not enable us to speak of the results of heroic treatment. We fancy it is many years since medical men have adopted any plan of treatment save that indicated above, when such diseases as tetanus or hydrophobia were under notice. The treatment of hydrophobia has been essentially conservative and expectant, and yet we know no single cure. The treatment of rabies is seldom attempted; but many dogs have been allowed to remain quiet and undisturbed in cages, rooms, or loose boxes; death has invariably terminated the case. The attempted distinction between ‘a natural and an artificial rabies’ has nothing to support it. Dogs frequently pass through the disease without any excitement, in what is known as dumb rabies, but this form is equally fatal with the violent condition. Certainly negative treatment has been fairly tried, and has proved useless. Until we can point to something more than a fractional percentage of doubtful recoveries, we must be content to allow the disease the unsatisfactory epithet, incurable. In the *Union Médicale* for June 23, M. E. Michel reports on the memoirs presented to the Medico-Chirurgical Society of Bordeaux, and directs special attention to nine papers on rabies. The second case in these memoirs refers to the ‘heroic treatment’ of a hydrophobic woman by the injection into the veins of warm water. These injections—fifty grammes at a time, amounting collectively to 700 grammes—seemed to afford some relief, the pulse and breathing becoming more regular and less frequent, but ultimately the patient died. The case is not very instructive, but, so far as it goes, is in favour of M. Decroix’s conclusions. The rest of the papers in the *Union Médicale* offer no further facts worth special mention as adding to our knowledge of the pathology or treatment of rabies.

The distinguished American physiologist, Dr. Hammond, has recently suggested a treatment of hydrophobia of a decidedly heroic nature. He advises the use of a continued electric current, and the application of ice to the spine. Decroix’s treatment is certainly more rational than this. Even supposing Dr. Hammond’s idea, that hydrophobia is a nervous disease, be true, it is difficult to see the *rationale* of his treatment. But it is utterly ridiculous when we know that the disease is simply dependent upon a specific poison in the blood. Rarely, very rarely, does rabies arise suddenly as the result of shock; but when it does, the explanation is that the period of incubation has been suddenly shortened.

Although we differ from Decroix, and believe that rabies is incurable, we agree with him that no heroic or exciting measures should be adopted from hope that medicine may yet triumph over this fell disease. The offer by Mr. Reilly, of Manchester, of a prize of 500*l.* for the best treatment or cure of hydrophobia, may be the means of adding to our knowledge. Properly applied, it might at any rate settle the real value of some of the secret but much vaunted remedies. Ex-

periments are requisite, but they must be well authenticated and minutely reported, so that public confidence be not reposed in a fallacy. Meanwhile we must trust to prophylactic measures, and attempt to stamp out the disease amongst animals by whom solely it is communicated to man.

ANATOMY AND PHYSIOLOGY.

PREVOST ON THE ACTION OF MUSCARINE ON THE PANCREATIC AND OTHER SECRETIONS.—In a recent communication to the Société de Biologie, in Paris, M. Prevost gave a *résumé* of experiments made with the toxic principle of *Agaricus muscarius*. He had studied the action of muscarine, 1. on the heart, which it was found to stop in diastole by excitation of the intracardiac nerve-centres; 2. on the intestine and bladder, in which it provoked strong contractions; 3. on the pupil, which it contracts; and 4. on the secretions of saliva, tears, and intestinal mucus, which it strongly excites. His experiments confirmed the results arrived at by MM. Schmiedeberg and Koppe, adding some new details. Like these observers, he noticed the antagonistic action of atropine, which immediately stops the phenomena produced by muscarine.

In a further series of experiments, M. Prevost has studied the action of muscarine on the pancreatic, biliary, and urinary secretions (*Comptes Rendus*, Aug. 10).

1. *Action on the pancreatic and biliary secretions.* The experiments were made on dogs, in which he laid bare the opening of the pancreatic and biliary ducts into the intestine, by a longitudinal incision of the duodenum. This was his usual method; but sometimes he made a pancreatic fistula.

Whether the animal was in digestion or fast, the pancreatic secretion was notably increased after injection of some milligrammes of muscarine into a vein. The excessive secretion ceased after intravenous injection of one or two milligrammes of sulphate of atropine.

There was also a great increase of biliary secretion; from a feeble flow before the injection of muscarine, it became abundant. The excessive secretion ceased, and the normal state was restored, after atropine was injected. These experiments were frequently repeated on different animals, and with the same results.

2. *Action on the urinary secretion.*—M. Prevost observed the changes produced in flow of urine by the ureters, after intravenous injection of muscarine. The experiments were made on dogs, cats, and rabbits.

He found the following method the best. A longitudinal incision is made above the pubes, in the median line of the abdominal wall, to an extent sufficient to produce hernia of the bladder. This organ is slit longitudinally throughout its height, and the edges of the wound sutured, on each side, to the lips of the abdominal wound. This operation may be quickly done, without hernia of the intestine. The experimenter is then in a position to observe the flow of urine by the ureter.

This process has the advantage of not modifying the urinary secretion, which is often the result of introducing a tube into the ureter.

One then sees the urine flow alternately at intervals of several seconds by each ureter, in the form of

small ejaculations coinciding with termination of the vermicular contraction of the ureter, which can be easily seen propagated even to the bladder. The orifice of the ureter in the bladder appears to open actively at each passage of urine. The flow of urine by the two ureters is commonly alternate; but sometimes it becomes simultaneous. In the normal state there are, in the rabbit, seven to ten outflows by the ureters per minute.

M. Prevost made careful comparison of the phenomena before and after the injection of muscarine. In eight such experiments he found that the injection of muscarine into the veins diminished the urinary secretion, and almost stopped it completely when the dose was strong. In all these cases, on the other hand, the lacrymal, salivary, biliary, and mucous secretions were considerably increased. Thus the urinary secretion presents a striking contrast to the others. Curiously, the injection of a few milligrammes of atropine into the veins suffices to restore the urinary secretion to what it was before injection of muscarine.

In several experiments on the rabbit, the author found that the urine, which was clear at the beginning of the experiment, came out turbid from the ureter after injection of atropine, presenting a character which is frequent in the rabbit's normal state.

En résumé, muscarine produces an excessive secretion from the liver and the pancreas, and diminishes the urinary secretion even to suppressing it almost completely for some time. These phenomena disappear under the influence of atropine, which may thus, in the above respects also, be regarded as antagonistic to muscarine.

ALEX. B. MACDOWALL.

DUNCAN ON THE NERVOUS SYSTEM OF ACTINIA. A paper on this subject, respecting which there has been much discussion, appears in the *Monthly Microscopical Journal* for August, from the pen of Professor Martin Duncan. An account is given of the observations of Howard, Haime, Schneider, and Röttken. Professor Duncan worked chiefly upon the actinia mesembryanthemum, and remarks upon the various difficulties that accompany the inquiry—the irritability of the muscular tissue, the variety of cellular histological elements, and the slimy character of the whole mass. It is difficult also to make thin sections. On examining the chromatophores he finds an outer bacillary layer consisting of sausage- or bolster-like cells, arranged vertically and separated from each other by a delicate layer of protoplasm. Beneath this is a little granular protoplasm containing small cells; then comes the second layer, which is composed of large, transparent, colourless, and highly refractile cells. In addition to these structures are the cones of Röttken, or the nematocysts with imperfectly visible threads of Howard. Some of these are elongated simple cells, faintly tinted, with tough cell-wall and rather viscid contents; others have a faintly striated cell-wall, and others again have a well-developed thread developed in their interior. The tissue between them is granulo-cellular protoplasm, and this often presents a filiform and branched appearance. Besides all these, Röttken described fusiform cells and fine fibres, which he believed to be a rudimentary nervous system, and in this view Professor Duncan is disposed to agree. He points out the difficulties of regarding the chromatophores as organs of special sense, since they are sometimes present, sometimes absent, in nearly allied

genera; still he thinks they may be regarded as the first faint outlines of eyes. He finds certain plexiform fibres at the base of the actinia.

CRUM BROWN ON THE SENSE OF ROTATION.—In the last part of the *Journal of Anatomy and Physiology*, Dr. Crum Brown states he has for some time past been convinced that we possess a sense of rotation quite distinct from all our other senses. By this means we are, he thinks, able to determine—(1) The axis about which rotation of the head takes place; (2) the direction of the rotation; and (3) its rate. His experiments were conducted by placing a stool on the centre of a table capable of rotating smoothly about a vertical axis. Upon this the experimenter sat, his eyes being closed and bandaged. An assistant then turned the table as smoothly as possible through an angle, of the sense and extent of which the experimenter had not been informed. It was found that with moderate speed, and when not more than one or two complete turns had been made at once, the experimenter could form a tolerably accurate judgment of the angle through which he had been turned. By placing the head in various positions, it was possible to make the vertical axis coincide with any straight line in the head. Considerable differences of accuracy exist in different individuals. The explanation given by Professor Crum Brown is, that each canal has an ampulla at one end only; and there is thus a physical difference between rotation with the ampulla first and rotation with the ampulla last; and we can easily suppose the action to be such that only one of these rotations (say that with the ampulla first, in which case, of course, there is a flow from the ampulla into the canal), will affect the nerve-terminations at all. One canal can therefore, on this supposition, be affected by, and transmit the sensation of rotation about one axis in one direction only; and for complete perception of rotation in any direction about any axis, six semicircular canals are required in three pairs, each pair having its two canals parallel, or in the same plane, and with their ampullæ turned different ways; and this is just what is found in all animals he has examined that have the exterior canal of one ear very nearly in the same place as that of the other, while the superior canal of one ear is nearly parallel to the posterior canal of the other.

MATERIA MEDICA AND THERAPEUTICS.

BIGELOW ON AMERICAN EUPATORIA.—Dr. J. M. Bigelow, of Detroit (*Detroit Review of Medicine*, August, 1874) says that the genus *Eupatorium* in the United States comprises about thirty-two species. Three have been found exclusively in the eastern states, five in the southern states, and eleven in the far west. Four species have been found common in the three grand divisions of the states, and nine are common to the eastern and southern states. Of those known to possess medicinal or toxicological properties, one (*Eu. sessilifolium*) is exclusively eastern, one (*Eu. incarnatum*) is exclusively southern, four, (*Eu. perfoliatum*, *rotundifolium*, *teucrifolium*, and *aromaticum*) are common to the eastern and southern states, while two (*Eu. purpureum* and *ageratoides*) are common to the whole United States.

Eupatorium perfoliatum is officinal. Its history

and properties are well described in Wood & Bache's *United States Dispensatory*. *Eupatorium teucrifolium* and *sessilifolium* possess similar properties, but appear to be milder in their operation than *eupatorium perfoliatum*. The root of *eupatorium purpureum* has bitter, aromatic, and astringent properties, and enjoys the local reputation of being an excellent diuretic, besides its tonic properties.

Burnett, in his *Outlines of Botany*, mentions that *eupatorium rotundifolium* is useful in consumption. It grows in dry soil near the sea coast, from Rhode Island to Louisiana.

Eupatorium incarnatum and *aromaticum* contain an aromatic principle, similar to, if not identical with, coumarin, first obtained by Guibourt from *coumarouna odorata*, Aub. (*diplexis odorata*, Schub.), or Tonka bean. This principle, or one very similar, seems to pervade many plants, such as *melilotus officinalis* and *cerulea*, *asperula odorata*, *trifolium melilotus*, *anthoxanthum odoratum*, *liatris odoratissima*, and probably many others. It is, without doubt, this principle which gives fragrance to *eupatorium incarnatum*, *purpureum*, *aromaticum*, *odoratum*, etc. *Liatris* is a genus of composites, very closely allied to *eupatorium*, and all species with aromatic fragrance and tuberous roots have long been known to possess active diuretic properties.

Professor Lindley, as long ago as 1848, mentioned the fact that bloody urine from inward contusions had been cured by coumarin, obtained either from the flowers of *melilotus* or the Tonka bean. This principle, besides being diuretic, is decidedly antispasmodic, and has been used by Dr. Cooper, of Philadelphia, in cases of pertussis.

There is a large class of troublesome diseases connected with inflammation and irritability of the bladder, in which the coumarin obtained from these plants—reasoning from analogy and the little experience we have already had of this substance—might be expected to produce decidedly beneficial results. Dr. Cooper gave to children of five years five to eight grains in a dose, prepared in the form of a fluid extract, with the happiest soothing effect upon the nervous system, which renders it worthy of a more extended trial.

Professor Wood (*United States Dispensatory*, p. 389, 13th ed.), with regard to the peculiar bitter principle of the *eupatorium perfoliatum*, remarks that, when the peculiar principle is isolated and satisfactorily determined, the name *eupatorin* will be proper; but he does not seem to remember that there are other species of *eupatoria*, possessing other and very different properties, and that some of them may have a peculiar principle isolated and satisfactorily determined before the *perfoliatum*, and will then be entitled to priority in the name. Under these circumstances, it would be manifestly improper to apply it to the peculiar principle of *eupatorium perfoliatum*. Already we see *eupatorin* (*perfoliatum*) and *eupatorin* (*purpureum*) advertised; but as yet neither of them is entitled to the name, as both are only concentrations of the several proximate principles, and not one peculiar to either of them. Eclecticism has a great penchant for the application and appropriation of scientific names; and among a large number of absurdities, we see *cerasin* and *prunin* advertised, which, if true alkaloids, as their names scientifically indicate, would be one and the same thing.

Eupatorium ageratoides, known popularly in some regions as white snake-root, is used by the eclectic

physicians of Ohio as an antispasmodic, diuretic and diaphoretic. In cases of nervous disease it is given in drachm doses, in the form of infusion.

But the greatest interest centered in this plant results from its having been suspected of being the cause of trembles in cattle and milk-sickness, a severe and sometimes fatal disease of very local extension, making its appearance in the early settlement of isolated regions in the south-western portion of Ohio. It pervaded also portions of Indiana, Illinois, Kentucky, and Tennessee. Like the old-fashioned tertian ague, it has disappeared entirely upon the clearing up and cultivation of the land, which also destroyed the abundant prevalence of the weed. The late Wm. S. Sullivan, a distinguished botanist of Ohio, writing upon this subject, in 1840, says that 'this weed, hitherto considered harmless, has lately become the suspected cause of the fatal disease among cattle called commonly the "trembles." The disease prevails in many localities in the western States, and is always accompanied by another equally fatal to the human species, known by the name of "milk-sickness." It is generally believed they are both produced by the same cause originally, whatever that may be. A prevailing opinion is that some vegetable produces it. The poison-ivy (*Rhus toxicodendron*) has been strongly suspected by many, among them the late Dr. Drake, of Cincinnati. Mr. John Rowe, of Fayette County, Ohio, asserts that he has been successful in investigating this obscure subject. It was with the eupatorium ageratoides that experiments on some cattle were made by him, in the presence of highly respectable witnesses. The disease was produced and the cattle died with it. An account of the experiments, together with the certificates of the witnesses, was published in the *Ohio State Journal* of 1840. The details were not given as particularly as could be wished.'

Mr. Sullivan was careful to ascertain that this was the plant used in those experiments, and also examined and identified specimens procured by Mr. T. Roberts, who was well acquainted with all the circumstances. He was assured also by Dr. Drake, of Cincinnati, to whom Mr. Rowe sent specimens, that it was the eupatorium ageratoides. A difficult point to settle in this case is, that this plant and likewise the poison-ivy are very abundant in many places where these diseases are not, and never have been known. Mr. Sullivan was better acquainted with the geographical botany of the west than any other individual; and, never having seen or heard of any plant peculiar to such infected localities, he therefore concludes that the origin of the disease will not be traced to any particular plant, and especially the plant in question, as it is found growing in the east, west, north, and south.

Although not directly related to our present subject, it may not be uninteresting to refer to a South American plant of this genus—*eupatorium glutinosum*. Professor Lindley remarks that the famous vulnerary, matico, said to be derived from *artanthe elongata*, a piperaceous plant, is really, according to Mr. Hartweg, the eupatorium glutinosum. The following is the memorandum of Mr. Hartweg addressed to Professor Lindley on the subject: 'Matico is the vernacular name applied by the inhabitants of Quito to eupatorium glutinosum, or the chessalonga in the Quichua language. It forms a shrub three to five feet high, and is common in the higher parts of the Quitinian Andes, where its properties were

discovered some years back by a soldier called Mateo, better known under his nickname Matico (Little Matthew), who, when wounded in action, applied accidentally the leaves of some shrub to his wound, which had the immediate effect to stop the bleeding. This shrub happened to be the chessalonga, which has since been called, in honour of the discoverer, Matico. That it is the true Matico of the inhabitants of Quito and Riobamba I have not the slightest doubt; both the leaves and specimens have been gathered by myself, and, upon comparing the latter with Kunth's description, I found them to agree exactly with his eupatorium glutinosum.' Mr. Hartweg was a botanical explorer of considerable distinction, having collected many rare plants in California.

The *United States Dispensatory* only refers to the Peruvian Matico (*artanthe elongata*); but, if the two should appear in market, as is not unlikely, it is important that the discriminating prescriber should know how to distinguish them.

Besides the eupatoria above enumerated, we have eleven or twelve western species, of whose properties little or nothing is known. One among them, eupatorium Berlandieri, common all over Texas, New Mexico, and extending into eastern Mexico, Dr. Gray says, is aromatic, and nearly allied to eupatorium aromaticum; so that, if further known, some might be found worthy of a place in the materia medica.

CHADWICK ON TRANSFUSION. — In a paper on transfusion, read at the annual meeting of the Massachusetts Medical Society (June 3, 1874), Dr. Chadwick, after a few historical references, says: 'Writers on this subject have all failed to emphasise the great distinction between the classes of cases to which the operation is applicable, and have consequently lost sight of the different indications for its employment.' He then proposes to divide the cases in which transfusion may be practised into four groups, 'basing the distinction upon accepted views as to the constitution of the blood in health and disease.' 1. In cases of serious hæmorrhage from any cause, transfusion of blood is recommended. 2. In diseases, such as cholera, etc., where the watery elements are extracted from the blood, a saline solution is advised. 3. Where there is wasting from malassimilation of food, or from other causes, 'blood is the only fluid which will meet the wants of the system.' 4. In blood-poisoning of any kind, it is suggested either that an antidote should be introduced into the circulation, or that the poisoned blood be removed and replaced by healthy blood. Dr. Chadwick then discusses the physiology of transfusion, and describes the different modes of operating. He does not, however, profess to have had any practical experience in the matter, but has 'merely sought to make out a rough chart for the use of future investigators.' [The reporter ventures to think, seeing there are many far better within the reach of most medical men, that the chart was scarcely called for. The grouping of the different classes of cases looks a little methodical; but the information afforded is meagre, and certainly not new. A record of fresh cases, and of new experiments bearing on the physiology of the subject, would be more useful, and is much wanted.—*Rep.*]

HENRY M. MADGE, M.D.

TOMMASI ON THE USE OF CARBOLIC ACID IN CHEESY PNEUMONIA.—Professor Tommasi states

(*M. Morgagni*, January, 1874, quoted in *Gazzetta delle Cliniche*, May 19) that he has found carbolic acid very useful in cases of cheesy pneumonia which have gone on to the formation of pulmonary abscess. The medicine is administered in the form of solution (one part in forty of water, sweetened). In two years he has met with six cases, of which he relates two.

The first case was that of a boy, aged six, who had hectic, sweats, extreme emaciation, and moderate expectoration of sanguineous foetid pus. Cinchona, lactate of iron, cod-liver oil, and raw meat produced but little improvement. He now had half a gramme of the carbolic acid solution daily, the dose being increased to a gramme. At the end of a fortnight the fever ceased, the expectoration diminished and became inodorous, and in four months he was quite restored to health.

In the second case, there was abundant expectoration of inodorous pus. The usual restorative means failed; but, after the solution of carbolic acid had been given in daily doses of a gramme to a gramme and a half, the expectoration diminished, and the patient became free from hectic and regained his appetite, and his nutrition was improved. In two months the expectoration had ceased, and a respiratory murmur, though weak, could be heard in the portion of lung which had been hepatised.

A. HENRY, M.D.

OBSTETRICS AND GYNÆCOLOGY.

SIMS ON INTRA-UTERINE FIBROIDS.—In a paper read before the New York Medical Society at Albany, in February, 1874 (*New York Medical Journal*, April, 1874) Dr. Marion Sims treats principally of the improved methods of removal of these growths when practicable. From the danger attached to surgical interference, he considers any operative procedure unjustifiable, unless where the patient's life is imperilled through exhausting loss of blood. His experience has taught him that intra-uterine fibroids are, for the most part, capsulated, occasionally polycystic, but more frequently solid. When cystic, the cysts vary in size from a filbert to an orange or a cocoa-nut. The more solid they are the easier is their removal. He gives five cases of successful enucleation of simple fibroid. The tumours were of various sizes, from a hen's egg to nearly two pounds; the latter was the largest pure myoma he ever removed from the interior of the uterus. He gives one case of successful removal of a fibroid cystic myoma as large as a seven months fetus. This was the second of that dimension which he had enucleated.

In these cystic cases the danger of excessive hæmorrhage from large venous sinuses, and of septic poisoning, is very great. Three fatal cases are related, and one nearly so from the introduction of a sponge-tent for a few hours to dilate the cervix. The patient recovered, and the profuse hæmorrhage ever afterwards entirely ceased.

In two of these lethal cases there were *post mortem* examinations. In one, a cyst containing about six or eight ounces of decomposed sero-pus was found attached to the walls of the uterus, whence the tumour was removed. In the other an abscess had burst into the peritoneal cavity, causing peritonitis. In the third case the lady died of 'uræmia, pro-

voked or called into action by the effects of etherisation.' She had œdema of the legs. The urine was not tested before the operation.

When fibroids are left to nature they may occasionally break through their investing capsule, and be extruded into the vagina, but so gradually as to cause little or no suffering, their presence becoming first manifest from the offensive discharges produced by the decomposition of the tumour, coupled with symptoms of septic poisoning. Two typical cases are reported by Dr. Sims as occurring in his practice.

The following rules are laid down as a guide to successful removal of these growths: 1. To open the cervical canal freely; 2. To free the tumour from its investing capsule. Enucleation should not be attempted until the cervix appears sufficiently dilated to permit of its passage, and even then not until the rounded end of the tumour presents at its external os. Failure is inevitable if the operation is begun before the fibroid is on a level with the internal os, i.e. if of large size. When it is not larger than an egg, these rules are not applicable.

The process of enucleation is illustrated by a typical case. Before commencing the operation the cervix should be softened by several sponge-tents being inserted into the canal six or eight hours previously. The operation is performed as follows.

The patient is placed in the left lateral semi-prone position, and the vagina opened by Sims's speculum. The tumour is then seized at its most dependent part by the volsella, and pulled forwards; the capsule is slit up with scissors at the point of its attachment to the posterior and lateral portions of the cervix, care being taken not to dissect the capsule from the cervix. The cut should be square into it. The index finger is now passed through the opening between the capsule and the tumour, the former (capsule) being left attached to the walls of the uterus. The capsule is next divided all round in close proximity to the borders of the cervix. As much as can be, is enucleated by the finger; through the inability of the finger to reach to the fundus, it is supplemented by the enucleator, a steel rod twelve to fifteen inches long, looped at the end to prevent it from perforating the fundus when pushed up. The tumour is firmly held and pulled forward by the volsella, whilst the enucleator is rapidly pushed between the tumour and its capsule up to the fundus. It is then withdrawn and pushed up in another quarter. This is repeatedly done, and when the strong fibrous bands are torn through, it is carried circularly around the tumour so as to insure its complete separation. As the fibrous bands have in some cases proved too strong to be torn through with the above-mentioned instrument, it has been modified by substituting a blunt hook bent at right angles with the shaft, the latter (shaft) slightly curved laterally so as to sweep round the tumour. As yet, the instrument has not been tried; but the author is certain that it is far more powerful than the old one and perfectly safe. The adhesions being satisfactorily torn through, the evulsion of the tumour is now undertaken by pulling it forcibly forward with the volsella and passing a double hook (the tumour-hook) along the posterior surface as far into the cavity of the uterus as possible. With this hook the tumour is pulled down and slightly rolled on its vertical axis, whilst the enucleator is used to separate any unbroken bands of attachment. As the mass yields to the gradual traction, another hook is passed

up higher, and so on, until with the combined use of enucleator and hook the body is brought away. Very frequently the os will not allow its free passage; when the cervix should be slit up with the scissors to the insertion of the vagina in four different directions. These deep incisions in the cervix heal without leaving a trace.

The tumour-hook is represented on the paper by a woodcut. It has a hard India-rubber shield, which slides along the shaft, and is pushed up to the hook when its removal is required for the purpose of changing its position.

On the removal of the growth, the uterus immediately contracts. All loose shreds of membrane are cut away with the scissors. The hæmorrhage is generally slight, but sometimes very severe. In order to guard against any danger of this sort, a plug of iron-cotton is passed into the cavity of the uterus up to the fundus, and kept in position by a vaginal tampon. The whole should be removed within thirty-six hours after the operation, and in less time if there be any symptoms of septic poisoning. The iron-cotton, as it is called, is prepared as follows. It should be of the finest and purest description of cotton thoroughly wetted in water, squeezed out, then saturated with a mixture of liquor ferri subsulphatis and water (one part to two), and pressed out into layers one-eighth of an inch thick, about the size of the hand, until they are nearly dry. They are now placed into a wide-mouthed bottle and securely corked, with a small amount of the iron mixture in the bottom, to secure a sufficient dampness. When used, these layers are subdivided into thinner layers, and pushed up into the uterus wrapped on a smoothly polished and well-greased piece of whalebone tapering to the point, which is slightly curved. The tampons are made cone-shaped, varying from the size of the thumb upwards. Should the first not be sufficiently large, a smaller one can be introduced by its side. They are kept in position by wads of iron-cotton placed over the os, with a plain cotton tampon, wet with water. This vaginal tampon should be removed in ten or twelve hours; the uterine at the latest in thirty-six hours, generally in twenty-four. The uterine tampons are removed by an instrument similar to the old wad-extractor, in the days of muzzle-loaders. On account of the firm adhesion of the tampon next the cervix, its removal is attended with greater difficulties. As soon as they are removed, the uterus should be thoroughly syringed out with carbolised warm water, repeated every four hours for the first six days and then every six hours.

Respecting the operation of gastrotomy for the removal of these growths, Dr. Sims remarks that, since the wonderful success that has attended M. Péan in seven out of nine cases, it will not be long before this operation is recognised by the profession as a justifiable one, and placed on a level with the major operation of ovariectomy.

BLACHEZ ON PUERPERAL TETANUS.—M. Blachez reports (*Gazette Hebdomadaire de Médecine et de Chirurgie*) a case of true tetanus, not one of those forms of muscular contractions occurring in the newly confined or nursing mothers, which was described by M. Delpuch (1846) under the name of idiopathic muscular spasms, or which Trousseau called *tétanie*, or which Dance long previously (1831) named intermittent tetanus (*tétanos intermittent*). The

patient was a woman forty-three years old, mother of ten children. During the last year, she had been subject to hysterics. She was confined of a puny eight months' child twelve days before her admission into the hospital. She got up, as was usual with her, on the fourth day. On the ninth day after her confinement, she felt difficulty in swallowing, and stiffness of the jaws. The dysphagia, trismus, and opisthotonos gradually increased in severity, until death took place on the fifth day after her admission into the hospital, and the thirteenth day after delivery. On admission, the temperature and urine were normal, the lochia were natural, and the breasts contained but little milk. The temperature gradually rose to 44.2° Cent. (111.5° Fahr.), and the pulse to 136. The temperature was not taken at the time of death. The treatment consisted of chloral, cupping, and the application of chloroform in spray along the spinal column. The necropsy, apart from congestion of the two lungs, especially the right, and a marked injection of the vessels at the base of the brain, exhibited no lesion. Careful microscopic examination showed nothing.

Although there is some analogy between the two affections, hysteric convulsions (*tétanie*) and tetanic convulsions (*tétanos*) and a resemblance as if of the same morbid species, still there is a sufficiently marked difference in their etiology, progress, and prognosis. 'Tétanie' is almost invariably a benign disease, and very rarely mortal; not so 'tétanos'; the latter has never been observed except in close connection with parturition, whereas the former has been observed during gestation or after many months of suckling. Trousseau states that young women are peculiarly liable to *tétanie*; not to tetanus (*tétanos*). Hysteric convulsion (*tétanie*) has a partiality for the extremities; the attacks are separated by a period of calm and health, the muscles of the jaw and chest are seldom invaded, and the temperature is normal. Tetanus generally occurs after some accident during labour, and is developed under the same unfavourable agencies that lead to the ordinary puerperal affections. The uterine wound plays a very important part in this disease, not so in the other. Simpson's hypothesis that hysteric convulsions was the result of some poison developed in the blood, is negated by the fact that they generally occur under the most favourable hygienic conditions. Hæmorrhage, obstetrical operations, moral impressions, and above all, chills, play a very important part in the production of tetanus, but the precise influence of such has never yet been made out. They are the chief agents in the etiology of all puerperal affections, not in tetanus in particular. In this patient there was an exalted nervous condition, as was shown by the hysterical attacks. Puerperal tetanus is as obscure as surgical. Deduct the puerperal condition, and they are the same; simple traumatic tetanus, consequent on injury.

W. C. GRIGG, M.D.

KEMPER ON INVERSION OF UTERUS; PROMPT REPLACEMENT.—Dr. G. W. H. Kemper reports (*Indiana Journal of Medicine*, March, 1874) an example of this in a woman aged thirty-three, in her sixth labour. Fifteen minutes after the birth of the child, a violent pain came on which expelled the placenta beyond the vulva, and completely inverted the uterus. His first suspicion of an inversion was caused by the uterus escaping his grasp above the pubes, and disappearing into the pelvis.

'There was no unusual amount of hæmorrhage,

and her pulse was good. There was not the least tendency to shock, and the woman was not aware that anything unusual had occurred, until I began reduction. Without waiting for chloroform or assistant, I hastily separated the placenta, which was adherent to the fundus, before attempting to replace the uterus. Pushing my right hand through the vulva into the vagina, while steadying the tissues above the pubes with my left, I indented the fundus with the tips of my fingers, and maintained a constant steady pressure in the direction of the axis of the pelvis. In about five minutes my efforts were rewarded with success. I kept my hand in the uterus for a few moments and satisfied myself that every portion had been fully restored, and that the outlines of the organ were distinctly perceptible through the abdominal walls.'

Dr. Kemper states that he had made but slight traction on the cord, not sufficient to cause the inversion.

PSYCHOLOGY.

VOISIN ON THE CURATIVE TREATMENT OF INSANITY BY CHLORHYDRATE OF MORPHIA.—Dr. Voisin, of the Salpêtrière Hospital (*Bulletin Général de Thérapeutique*, March, 1874) arrives at the following conclusions.

If the malady be recent and not complicated by successions of delusions, the remedy keeps it from progressing, and stops the development of secondary or tertiary stages. Moreover, it calms the general or partial agitation in a time varying from two to three hours after a sufficient quantity has been injected. This dose is very variable, and is only arrived at by experience. The manner in which the delirium disappears is interesting. The delusions, hallucinations, etc., seem to separate off from one another and no longer to form part of the same whole; they disappear one after another, and the patient replies to questions and recognises that he has been ill, his memory returns, and he recounts a series of facts relating to his entry to the hospital, he writes to his family and allows himself to be treated medically without offering any resistance. It seems as if the symptoms of insanity disappear inversely in the order of their occurrence. Thus the patients who have begun by hallucinations followed up by delusions, in their recovery lose the latter before the former, and though the hallucinations may remain for some days they do not believe in them. The indications for the remedy are: melancholia, with or without hallucinations; ecstasy; suicidal ideas religious delusions; maniacal excitement; the various forms of neuralgia which are so common amongst the insane, and especially in the women, which often determine the especial character of the delusions, giving, *e.g.*, the notion that they are being electrified. The peculiar form of *folie circulaire*, which is generally thought to be incurable, has been very successfully treated by it.

The contra-indications for its use are: inflammatory symptoms, epileptic insanity, and general paralysis. In that form resulting from atheroma of the arteries, it may cause mischief from congestion, leading thence to hæmorrhage.

Of the twenty-five cases quoted which were cured, six were affected with general mania with hallucinations and incoherence. The strongest dose employed in these six cases was twenty-one centigrammes daily,

and the smallest was thirty-one milligrammes daily, the average duration of the treatment being four months. The other successful cases were of melancholic form, with more or less suicidal and homicidal complication.

Of the five unsuccessful cases, four had delusions of wealth and power, and one had certain febrile complications, a condition which has been shown by later experience to be totally opposed to the proper use of the remedy.

The subject will be continued in another number.

WILLE ON AID-SOCIETIES FOR THE INSANE.—Dr. Wille (*Irrenfreund*, no. 4, 1874) writes in favour of the formation of associations whose aim is the protection and help of the insane, because this class of persons is little understood in general, and therefore is at a great disadvantage. Hence one function of the association is to diffuse true and liberal ideas on insanity among the public. Another is to see that proper cases are taken to the asylum at the right time, by affording help to a poor man's family when he is taken ill, so that he can be at once removed and not compelled to work. At other times the help need not be material, but consists in protecting the property and interests of those already under restraint from people who would squander the one and spoil the other. When a patient leaves the asylum cured, it is generally to find himself worse off than before; he is often exposed to the cruel remarks and taunts of neighbours who decline to place confidence in him, and so his means for supporting the family are gone. At such a time the association supplies either food, money, clothes, or working tools, under conditions properly secured. Such institutions have long been founded in France—*sociétés de patronage*—and they have spread over all the departments, receiving support from all sorts of clerical and lay bodies, and increasing their funds by collections, lotteries, etc. Belgium possesses clubs of the same kind. Other countries have not done much, though exceptions must be made in favour of Colney Hatch, and the Bavarian Asylum at Illenau.

The labours of Dr. Zinn, at St. Gall, in Switzerland, and of Dr. Hund in Münsterlungen, canton Thurgau, in this direction, should be recognised.

In 1860 some philanthropic men of the canton Lucerne founded an asylum, and collected a fund of 8,000*l.* towards the object in question.

The paper concludes by giving a scheme for the management, viz., by a committee sufficiently large and composed of men with practical experience and large sympathies.

T. C. SHAW, M.D.

OPHTHALMOLOGY AND OTOLOGY.

BULL ON RETINAL HÆMORRHAGE AND ITS CONNECTION WITH CEREBRAL, CARDIAC, AND RENAL LESIONS.—The *American Journal of the Medical Sciences*, July 1874, contains an important article by Dr. Charles S. Bull, on this subject. The general history and the causation of retinal hæmorrhage are first discussed; and then the connection of special forms of hæmorrhage with the diseases of the brain, of the heart, and of the kidney is traced as far as our present knowledge of the subject will allow.

Retinal hæmorrhages may have a twofold origin ; that is to say, their exciting cause may be either intrinsic or within the eye, as in neuro-retinitis, retinitis or glaucoma, and extrinsic, when it is due to cardiac or to chronic renal disease. Dr. Bull agrees with most writers in speaking of three forms of hæmorrhage ; namely, the small round spots, circumscribed and many in number, the longitudinal streaks or brush-like bands when the blood is within the nerve-fibre layer, and the large and irregular patches which usually occur in the neighbourhood of the large veins. In some cases in which the extravasation is extensive the vitreous body is involved, but as a rule the tendency of the blood is to spread towards the choroid.

Retinal apoplexy from whatever cause has a marked tendency to recur, and, as an independent lesion, rarely occurs except in advanced life ; it is almost always associated with other structural lesions. It occurs with disease of the heart, and especially when this is associated with general atheromatous degenerations ; and in all cases of retinitis the walls of the vessels necessarily soon become involved.

As regards the subjective symptoms, there may or may not be premonitory warnings, but it is a characteristic of such lesions that they occur suddenly. Whether constitutional syphilis predisposes to retinal apoplexy, is uncertain. It is generally said of syphilitic retinitis that it is but rarely marked by hæmorrhages, but in a report by Mandelstamm of nine cases of this form of retinitis, which occurred at Wiesbaden in 1863—1866, it appears that four of them were accompanied by hæmorrhage. It appears to occur more frequently in men than in women, and generally after fifty years of age ; in fact, in the same report above mentioned, of twenty-six cases of retinal apoplexy, twenty-two occurred in patients from fifty to eighty years of age, and twenty-four of the twenty-six cases were in men.

The most important point in connection with retinal hæmorrhage is whether or not it may be regarded as a premonitory sign of cerebral apoplexy. A sufficient number of cases has not as yet been tabulated, though there is already a good deal of evidence to support the idea. Dr. Reynolds considers that clots in the retina are to be regarded as warning symptoms of a cerebral lesion ; Dr. Tanner speaks of them as being so ; and Dr. Hammond says he has known retinal hæmorrhage to precede by more than a year the occurrence of a more serious lesion.

Dr. Colman has reported a series of cases in the *Berliner Klinische Wochenschrift* (February, 1870), some of which were followed by cerebral apoplexy ; and Dr. Bull has observed four cases in which he was able to verify the occurrence of cerebral apoplexy subsequently to the intraocular lesion. These he records at some length in his present paper. Lastly, Dr. Berthold, in the *Klinische Monatsblätter für Augenheilkunde*, for April, 1874, records the case of a woman, between thirty-five and forty years of age, who came to him with a hæmorrhage into the macula lutea, and who, while under examination, suddenly fell back and died, with all the appearances of cerebral apoplexy.

Dr. Bull enters at length into the explanation of the connection between retinal hæmorrhage and chronic Bright's disease, as given by Dr. George Johnson in the *Medical Times and Gazette* for July 2, 1870 ; and, while assuming the correctness of Dr. Johnson's views as regards the hypertrophy of the muscular coat of the small arteries, he suggests that the cases in which no hæmorrhages occur may

be explained by the increased power of the vessels being able to balance the increased action of the heart ; and that the hæmorrhage is caused by the want of this balance, when, in fact, the hypertrophied left ventricle is not accompanied with a proportionate hypertrophy of the smaller arteries. The limited number of observations on record agree in assigning the capillaries, or at least the small vessels, as the source and the seat of the hæmorrhage.

WARLONT ON A NEW METHOD OF OPERATION FOR ENTROPION AND TRICHIASIS OF THE UPPER EYELID.—The *Annales d'Oculistique* for May and June, 1874, contains an account of a new operation for the cure of these troublesome and distressing cases, and one which Dr. Warlomont has practised with great advantage. After passing in review the methods recommended by Anagnostakis, by Von Graefe, by Williams, and by Streatfeild, all of which are good in their way, but each and all leaving something to be desired, Dr. Warlomont describes and recommends his own plan of proceeding as presenting the following advantages.

1. The operation may be as extensive as the surgeon pleases.
2. A recurrence of the inversion is rendered impossible.
3. The skin of the eyelid is unhurt, and the subsequent scar is almost imperceptible.

The operation consists in detaching the margin of the eyelid, with the offending eyelashes, from the subjacent tissues, and fixing it by sutures to the upper border of the tarsal cartilage, previously laid bare by a careful dissection. It is carried out as follows.

The patient is placed under chloroform, and the upper eyelid is fixed and compressed by a modified form of ring-forceps, which will be subsequently described. An incision is then made through the skin only, parallel to and at a short distance from the ciliary margin ; the skin is then dissected from the orbicularis muscle as far upwards as the ring of the forceps, so that a semilunar flap is formed of integument alone. The margin of the eyelid is then transfixed from above by a narrow double-edged knife, which detaches the row of eyelashes, or so much of it as is required, in such a way as to split the margin of the eyelid into halves, except at the extremities of the section. The narrow flap of integument containing the eyelashes is then drawn upwards, and is fastened by three or more sutures to the upper margin of the tarsal cartilage, which has been exposed by the previous dissection of the skin. The margin of the eyelid, bared of its eyelashes, is left to granulate over, and the flap of integument falls naturally into position, and requires no sutures. The threads are removed at the end of three or four days, when the union is generally found complete.

The ring-forceps which Dr. Warlomont employs is a modified variety of those generally in use. There is, as he says, a well-known objection to the ordinary form of instrument, in that its grasp upon the eyelid is limited, especially in breadth, so that it very often fails to include the entire row of eyelashes upon which the surgeon may wish to operate, and thus the operation is rendered incomplete. With the forceps which Dr. Warlomont has devised, this disadvantage is overcome in an ingenious manner ; the upper blade or ring is made to expand laterally, by means of a screw, and may thus be adapted to any length of the eyelid that may be desired ; at the same

time, and by a similar arrangement, the under and solid blade can be made to expand like a fan. The instrument was originally described by Dr. Warlomont in the *Klinische Monatsblätter*, December, 1873, having been previously mentioned at the Heidelberg Congress. It is now fully described, with an illustration, in the May and June number of the *Annales*, and with some improvements.

The instrument has been called the 'fan-shaped eyelid forceps,' by Dr. Warlomont.

BOWATER J. VERNON.

PFLÜGER ON HERPES CORNEÆ.—Dr. Pflüger of Luzern relates a case of herpes corneæ, in Zehender's *Klinische Monatsblätter für Augenheilkunde* for April and May, depending upon excessive use of the eyes by artificial light. After trying the usual modes of treatment by atropine, rest, iodide of iron, quinine, arsenic, etc., without effecting any change, he applied a constant current, placing the anode on the closed lid, directly over the cornea, and the cathode on the neck. Under this treatment, applied daily for from five to ten minutes, only one new crop of three vesicles appeared, while formerly there had been a new daily crop of from eight to twelve.

W. LAIDLAW PURVES.

ELECTRO-THERAPEUTICS.

RODOLFI ON THE TREATMENT OF HYDROCELE BY ELECTRICITY.—In the *Gazzetta Medica Italiana-Lombardia* for March 15, 1873 (see LONDON MEDICAL RECORD, June 25, 1873), Dr. Rodolfi, of Brescia, described a method of treating hydrocele by electricity, in which he operated by applying to the inner surface of the sac a copper probe, connected with the negative pole of a battery. He now relates (*ibid.* August 8, 1874) several cases in which this operation has been practised.

Case 1. Luigi Mazzuno, aged forty-five, was admitted on January 19, 1873, with hydrocele of the left tunica vaginalis. The hydrocele had existed about a year, but within the last two months it had become as large as the head of a new-born child. On the 19th, 20th, and 21st he had doses of the 'preparatory powders,' which Dr. Rodolfi always gives before operations, consisting of bicarbonate of potash, flowers of sulphur, and nitrate of bismuth. On the 21st, 700 grammes (more than twenty-four ounces) of yellow serum were removed; and Dr. Rodolfi operated in the manner already described, carrying the probe in connection with the negative pole over the whole inner surface of the sac for about twelve minutes. During the operation, the patient complained of slight burning at the point of puncture, and of a slight shock at a moment when the current was accidentally interrupted. The next day there were enlargement of the left testicle and œdema of the scrotum; these symptoms, however, were not accompanied with pain, and disappeared in a few days. On February 19, a month after the operation, the patient was discharged cured, there being firm adhesion of the tunica vaginalis. In the following November, Dr. Matanza of Adria, the place of Mazzuno's residence, informed Dr. Rodolfi, in reply to a letter, that the man remained in perfect health, the hydrocele being radically cured.

Case 2. Giacomo Roli of Pralboino, aged ten,

was admitted to hospital on February 5, 1873, with hydrocele of the left tunica vaginalis. The following day fifty grammes of yellow serous fluid were removed, and electricity was applied from two Bunsen's piles, charged with solution of bichromate of potash. The operation, which lasted six minutes, was attended with some pain, while the probe was passing over the inner surface of the sac. On the 7th there was evident reaction; the testicle was enlarged, and the scrotum red. The enlargement continued on the next day; it then gradually diminished, and on the 15th he was discharged cured. On September 16, Dr. Barchi of Pralboino wrote to Dr. Rodolfi (in answer to his inquiry) that there was a partial reproduction of the hydrocele.

Case 3. Giovanni Enghelben, of Calcinato, aged fifty-three, was admitted into hospital on February 5, 1873, with hydrocele of the left tunica vaginalis. It had existed two years, and had gradually increased. On the 7th 400 grammes (about fourteen ounces) of fluid were drawn off, and the electric current was applied (from three Bunsen's piles) for ten minutes. Slight pain was occasionally felt. Next day, the testis was twice as large as the other, but there was no pain. Soon afterwards, sac again became filled; and, on March 8, the operation was repeated, two of Bunsen's piles and one of Grenet's being used. The patient left the hospital three days afterwards; the epididymis was somewhat enlarged, and the scrotum apparently in a normal state. On December 8, he was again admitted with a hydrocele as large as an ostrich's egg. Believing that the former failure had arisen from the current being too weak, Dr. Rodolfi operated on December 12, with five powerful Bunsen's piles, the application being continued during twelve minutes. Some days later, a collection of fluid again appeared. Drainage was now used, and by this means a radical cure was effected. The patient left the hospital on February 11, 1874.

Case 4. Faustino Ferrazzi, of St. Gervasio, aged fifty was admitted on March 5, 1873, suffering from pellagra. The next day, it was found that he had hydrocele of the left tunica vaginalis. On the 7th 500 grammes (between seventeen and eighteen ounces) of fluid were removed; and, in order to meet the objection of some who believed that the good result of the treatment was due to mechanical irritation alone, the end of a probe was simply passed over the inner surface of the sac for twelve minutes. Next day the testis was somewhat swollen and tender, and the sac soon afterwards became filled. On the 28th, after drawing off the fluid, Dr. Rodolfi applied electricity for ten minutes. On the fourth day after the operation, the hydrocele began to reappear, and on April 20, the operation was repeated. It was found that the previous operation had produced adhesion of one half of the sac. The apparatus now used consisted of three Bunsen's pairs and one Grenet's. On May 4 some swelling and deep fluctuation was detected near the inguinal ring. On making an exploratory puncture, pus escaped. A drainage-tube was introduced, and the patient was discharged cured on June 6. On December 23 Dr. Volpi, of San Gervasio, wrote to Dr. Rodolfi that the drainage-tube was removed on August 1, and that the hydrocele remained perfectly cured.

Case 5. Giacomo Inama, of Brescia, aged forty-nine, was admitted on March 5, 1873, with hydrocele on the right side. On the next day 260 grammes of fluid were drawn off, and the galvanic current (from two Bunsen's and one Grenet's pile) was applied for

twelve minutes. On the 8th the right scrotum was of the size of a lemon, painful only on pressure, and the skin was of a vivid red colour. On the 17th there was slight fever, and on the 21st the swelling began to diminish. On the 23rd, there was some sloughing of the tissues at the point of puncture, with detachment of part of the subscrotal cellular tissue, probably from imperfect isolation of the probe during the operation. The man again visited the hospital at the end of January, 1874. There had been no return of the hydrocele.

Case 6. Angelo Peroni, of Brescia, aged forty-three, was admitted on April 13, 1873, with hydrocele of the left tunica vaginalis. Two days afterwards 250 grammes of fluid were drawn off, and a galvanic current from four pairs was applied for ten minutes. Two hours after the operation the patient was attacked with severe pain in the left testicle, passing along the spermatic cord and to the loins. It was relieved by the local application of ice, and the internal administration of chloral. He left the hospital on April 24. The cure remained for about six months; but he was again admitted in October with a return of the hydrocele. The operation was repeated on the 20th; and in June of this year there was no sign of reproduction of the malady.

Case 7. Giacomo Boselli, of Mairano, aged sixty-six, a very emaciated subject, was admitted on June 18, 1873, with hydrocele of the left tunica vaginalis. After a few days of preparatory treatment, 250 grammes of fluid were drawn off on the 29th, and the current from three Bunsen's pairs was applied for twelve minutes. The operation produced only a slight sense of burning. He left the hospital on July 20. On December 2, Dr. Rivetti, of Mairano, wrote that he had seen Boselli on the previous day, and that there was no trace of hydrocele.

Case 8. Andrea Baccolo, of Rivoltella, aged forty-seven, was admitted on July 19, 1873, with hydrocele of the left tunica vaginalis. On the 23rd, 200 grammes of fluid were removed, and the current from four Bunsen's pairs was applied for twelve minutes. There was no reaction, and he left the hospital on August 14, apparently cured. On September 24, however, he was admitted, the hydrocele having returned. Six days afterwards, the operation was repeated; six Bunsen's pairs being used, and the duration of the application being thirteen minutes. The next day there was much swelling of the testicle; this increased for ten days, but then gradually diminished. The patient left the hospital cured, on October (? November) 1. On April 14, 1874, Dr. Pasetti, of Rivoltella, wrote to Dr. Rodolfi that there had been no return of the hydrocele.

In summing up the results of these cases, Dr. Rodolfi observes that three (1, 5, and 7) were radically cured; two (6 and 8) required a repetition of the operation; in two (3 and 4) drainage was required to complete the cure; and in one (2) the hydrocele returned at the end of three months, but the patient did not again submit himself to operation. The failure in some cases, he believes, lies in the manner of operating rather than in any conditions of the patient. When the probe was carried continuously over the inner surface of the sac, the result was not favourable; but when it was allowed to rest for a short time in contact with a portion of the membrane, the reaction was more evident and the cure complete. He has hence adopted the plan of allowing the end of the probe to remain in contact with various parts

of the inner surface of the sac for twenty or thirty seconds; the entire operation lasting ten minutes.

A. HENRY, M.D.

NEW INVENTIONS.

NEW APPARATUS FOR THE TRANSFUSION OF BLOOD FROM ARM TO ARM.

This new apparatus, the fruit of much study by M. Mathieu, the surgical-instrument maker of Paris, was submitted to the Académie des Sciences of Paris and has obtained their approval. The apparatus consists of a glass receiver (F) communicating with a funnel (A) into which the blood is poured through a glass tube. A small India-rubber tube (B) is fitted to the receiver. Between the funnel and the receiver is an India-rubber bulb (D), which is traversed by the tube communicating between the two. This bulb, which is exclusively a reservoir of air, communicates by an opening with the glass receiver, and its compression has the effect of driving out from the latter a quantity of air proportional to the capacity of the bulb. When this regains its normal form, in consequence of its elasticity, it draws a part of the air from the receiver; the blood poured into the funnel overcomes the resistance offered by the India-rubber tube, which acts as a valve and enters the receiver. If, when the latter is half filled, pressure be made on the India-rubber bulb, the air contained in it, driven back into the receiver, presses on the liquid column

like a piston, and drives it into the conduct-tube (G) of the receiver, towards the vein. When after the first result has been obtained, the bulb is allowed to re-inflate itself, it takes the air from the receiver, a corresponding vacuum in which is produced; the blood is drawn into it, to be expelled by a fresh pressure on the bulb. Thus the elasticity of the bulb is the sole motive power of this apparatus, by alternately drawing the air of the receiver into the internal cavity, and driving it back from that hollow space into the receiver. It is this flux and reflux of the column of air from one hollow space to the other that is the condition of the motion imparted to the

blood in a manner determined by the arrangement of the valves.

Rapidity of operation is claimed for this new system; and as one minute only is said to be necessary for it, coagulation of the blood is not to be feared. By substituting the cannula of an ordinary syringe for the cannula K, which is used for transfusion, every kind of injection can be performed with this apparatus, without any fear of the introduction of air. By placing the India-rubber tube in the opening at the bottom of the funnel, its action on the bulb makes it into an aspirator, as above stated. When the apparatus is out of use, in order to keep the India-rubber bulb in good order, some water should be aspirated into the reservoir. For this purpose the apparatus should be turned upside down, the bulb should be compressed, and then allowed to re-inflate itself, when the water will enter it, and remain there until the apparatus is again called into requisition.

REVIEWS.

Clinical Medicine: Lectures and Essays. By BAL-THAZAR FOSTER, M.D., F.R.C.P., Professor of Medicine in Queen's College, and Physician to the General Hospital, Birmingham. 8vo, pp. 364. London: J. & A. Churchill. 1874.

Under this title Dr. Foster has gathered together a series of valuable monographs, which he has communicated from time to time to various medical journals, and in doing so has laid the profession under an obligation to him. An acute observer and an accurate reasoner on the phenomena of disease, he possesses the faculty of laying his conclusions out in clear and precise language. This collection of papers deals with various divisions of medicine, but especially with those of disease or disorder of the assimilative and circulatory systems. The first paper is on the Treatment of Ulcer of the Stomach, in which the different points to be attended to, in order to secure a satisfactory result, are laid down distinctly and intelligibly. In succeeding papers, Dr. Foster gives us some very interesting information on several points. One is the effect of ether upon the pancreas in increasing the flow of pancreatic fluid, and so securing the emulsification of a larger quantity of fat in the intestinal canal; by this means the assimilation of fat by the consumptive patient may be increased to the patient's benefit. This is a valuable idea, and should be tested by several separate observers, in order to see how far the plan is effective. Then follow some observations on the formation of lactic acid, and its relation to diabetes, of a practical nature. It is interesting to know that the treatment of diabetes by lactic acid has been productive of much corroboration of the theory of the lactic acid origin of acute rheumatism. In two of Dr. Foster's cases, this result was attained several times by resuming the lactic acid. Something yet unknown is required to produce the result in certain cases, which factor seems wanting in others.

In the papers dealing with the circulatory system there is much that is valuable. The practical importance of the sphygmograph and cardiograph in the diagnosis of diseases of the heart is clearly demonstrated. These means furnish valuable information even in tricuspid stenosis, a disease whose diagnosis up to a recent period has been regarded as

a theoretic possibility only. The diagnosis of the rupture of the aortic valve by violence, and the accurate prognosis founded thereupon in several cases by Dr. Foster, are clinical feats worthy of Skoda himself. The importance of recognising the anatomical fact that one aortic valve-segment has no coronary vessel springing from its sinus, and the consequent effect upon the nutrition of the heart and the maintenance of compensation in lesions of different valve-segments is well shown in the paper, which should be carefully coned by all stethoscopists. In reference to the use of digitalis, the writer's views are in accordance with the modern impressions as to its sedative action on the heart being due to its tonic effect rather than any palsyng action. The sentence 'digitalis restores the normal balance between the contents of arteries and veins' deserves a place as a permanent quotation in text-books on remedies. Dr. Foster's criticism of Dr. Peacock's explanation of the relation of diuresis to the condition of the circulation is well worth perusal.

Indeed, there is so much both practically valuable and also suggestive in this book of Dr. Foster's, that we can only hope that this volume will not be permitted to stand alone, but will ere long be followed by an equally worthy successor.

MISCELLANY.

THE PLAGUE IN NORTHERN AFRICA. — We learn from a correspondent that this scourge has extended itself to a village called Maish, about ten hours' journey from Bengazi.

DR. GRANT, F.R.S., Professor of Comparative Anatomy and Zoology in the University College, London, died last week at the age of eighty. He had held the professorship from the establishment of the college in 1828, and was the last survivor of the professors first appointed.

AN INDIGESTIBLE MORSEL. — At a late meeting of the Société Médicale des Hôpitaux in Paris, M. Dujardin-Beaumetz exhibited a flattened leaden bullet which had been swallowed by a child. It had remained eight days in the digestive organs, produced asphyxia at the outset, and was voided naturally without having given rise to the least symptom of lead-poisoning, after treatment consisting of the administration of purgatives and sulphuric acid lemonade.

THE DOG-HEADED MONKEY. — A full-grown specimen of the dog-headed monkey from Abyssinia has been presented to the museum of the University of Geneva. This monkey is characterised by the long hair upon its cheeks and the greater part of its body. It was held in veneration by the ancient Egyptians. Its figure is engraved upon the monuments of ancient Egypt, and there have been found mummies of the animal well preserved. According to Ehrenberg, this monkey served as the emblem for the god Thoth, the Egyptian Hermes, or Mercury, the mythical inventor of the arts and sciences, music and astronomy, and especially of speech and hieroglyphs, or letters, over which he was supposed to preside. The Abyssinians now call it Tota. Horapollon reports that this monkey was consulted in the temples; a tablet, reed, and ink, presented by a priest, were used as tests to ascertain if the particular animal belonged to the race that knew how to write. This representative of Thoth also symbolised the judgment of souls; and upon one of the temples of Philæ there is one represented with a balance in hand weighing the actions of men. In other places it is represented writing with a reed. Ehrenberg also supposes that it is the locks of this monkey that have served as the model for the perruques figured upon the heads of different divinities in the Egyptian mythology.

A NEW JOURNAL.—Messrs. Putnam & Sons, of New York, announce for October 1, a new quarterly journal of skin and venereal diseases, to be called the *Archives of Dermatology*. The journal will be edited by Dr. Duncan Bulkley, who will be assisted by a staff composed of the most eminent dermatologists and syphilographers of the United States. The German journal of the same subjects, ably edited by Drs. Pick and Auspitz, under the name of *Archiv für Dermatologie und Syphilis*, has now substituted the name *Vierteljahrsschrift für Archiv* in the title, and is published at Vienna in place of Prague.

UNDERGROUND AIR.—The hope of reward is no doubt a more generally powerful stimulus than the love of service. It is not surprising, therefore, that with the view of encouraging traffic, the authorities of the Metropolitan Railway have added smoking-carriages, after having satisfactorily demonstrated, when the question was discussed in Parliament on the score of public convenience, that it was impossible for them to do so. We believe that the present step will be satisfactory to the company and to smokers, but, in order to make it equally so to all travellers, we must suggest that some further attention be paid to ventilation. The existing flavour of sulphur, steam, and coal-smoke which pervades the atmosphere of the tunnels on the Metropolitan Railway is, to say the least, unpleasant; and the addition of a pervading cloud of stale tobacco-smoke might, we imagine, add to it the last touch of intolerable nastiness.

DECADENCE OF THE UNIVERSITY OF BERLIN.—The diminution in the number of students at the University of Berlin, which had already been noticed during the last three months of the summer of 1873, has again been observed during the six winter months of 1873-74. The *Gazette de Cologne*, commenting on this falling off, remarks that hitherto as a rule the University medical courses were more numerous attended than the other ones. It seems, however, certain that the number of students of medicine has sensibly diminished; one professor having 100 fewer students in his class than he had in the preceding year. In short; the number of students has reached its lowest point in comparison with former years. The University is now outstripped in numbers, not only by that of Leipzig, but also by the University of Göttingen, which now contains 1,000 students. It appears that in Germany the salary of the professors, which, inclusive of the students' fees, is considerable, is only increased if they be requested to transfer their services to other seats of learning, and if their departure be considered injurious to the interests of the university which they have hitherto taught. Thus distinguished professors have been drafted to the University of Berlin, but this has not been accomplished without promising them double the salary offered some years since. This increase of salary is rendered imperative by the continually increasing price of the necessaries of life in Berlin, as in other parts of Germany.

A PROFESSIONAL LAWSUIT.—A philanthropic lady, Frau Riedl, who died in Vienna last January, bequeathed 100,000 florins for the erection of a hospital for children in Liechtenthal, and in her will, appointed the medical faculty of Vienna as her executors and administrators of the fund. At that time the medical faculty consisted of the College of Physicians and the College of Professors. By the New University Act passed since her death, the College of Physicians has been separated from its connection with the university and faculty. As the result of this sudden change, the College of Professors claimed the sole management of the above-mentioned sum, and wished to build the hospital in Liechtenthal and to use it for teaching purposes; while the College of Physicians, on the other hand, claimed a common management, since the will of Frau Riedl was executed at a time when the physicians were still united with the university and faculty. They also protested against the conversion of the proposed hospital into a clinical school, which seemed to be the

object of the professors. The circumstances under which Frau Riedl, the sister-in-law of Dr. Lamatsch, one of the most faithful fellows of the College of Physicians, bequeathed this sum to the above-mentioned object, shows that by the medical faculty she meant the College of Physicians, and indeed this was the general understanding of the case in Vienna at the time. The inexorable determination of the College of Professors rendered a suit at law unavoidable. The Court decided that Frau Riedl intended the fund to be under the control of the different bodies at that time constituting the university. Although these are now separated, each retains a voice in the management.

SODA-WATER.—Dr. Lankester, the Medical Officer and Public Analyst of St. James's, has made a report on this beverage, as sold in his district, which deserves attention. 'This liquid,' he says, 'is sold in bottles, and is professedly an imitation of some natural springs which contain a certain quantity of carbonate of soda and carbonic acid. In England this water is entirely an artificial preparation, and is sold by chemists and druggists as a medicine, and by publicans as a beverage. It is supposed to contain from ten to fifteen grains of carbonate of soda in a bottle containing about ten ounces of water. The medicinal agency of this beverage consists in its carbonate of soda, and it becomes a matter of importance for sick people and convalescents, for whom this liquid is ordered, that they should have the supposed quantity of soda in the water.'

From an examination of six specimens of this water bought at chemists and druggists and publicans, I found that none of them contained in the bottle a residue of ten grains; that various other salts besides carbonate of soda were contained in the water, and that in some of them was a considerable quantity of organic matter.

'The conclusion I came to was this: that none of these waters were genuine mineral waters; that most of them contained less saline matter than the mineral water they represent contain; and that the only thing they contained in tolerably certain quantity was carbonic acid gas.'

It is certainly not pleasant to know that in artificial aerated waters the only thing tolerably certain is that we drink water laden with organic matter that is dangerously impure and charged with gas. When to this is added the danger of occasional lead-poisoning, it is not surprising that natural effervescent water of absolute purity and stable composition is beginning to acquire a preference over the soda and seltzer-waters of commerce.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S.W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

WEDNESDAY, SEPTEMBER 9, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The following were among the papers read during the recent meeting in the department of Anatomy and Physiology, under the presidency of Professor Redfern.

Mr. B. Waterhouse Hawkins, F.L.S., F.G.S., made some observations, with graphic illustrations, on a pair of symmetrical bones present with the fossil remains of *Iguanodon* in the well-known slab from Maidstone, now in the British Museum, and compared those bones with their analogue, as found with a portion of the fossilised skeleton of *Hadrosaurus Foulkii*, in the marl beds of the cretaceous formation at Haddonfield, in New Jersey, North America. The bones in question had been described by Professor Owen and others as clavicles; but Mr. Hawkins, in making his restorations for the Park of the Crystal Palace, was unable, owing to the great length of the bones, to make room for them in his *iguanodon*, and he therefore had to abandon them, and make his model in such a manner as would be consistent with the animal being able to walk. A subsequent comparison of the bones with those of the American analogue led to the conclusion that they were abdominal, and the situation which Mr. Hawkins thought they occupied suggested the possibility of the *iguanodon* being a marsupial animal.

The President thought that Mr. Hawkins had, by his illustrations, completely demonstrated his position.

Dr. Pye-Smith said that the conclusion at which Mr. Hawkins had arrived was so startling that one would rather be disposed to replace the bones in question in their position of uncertainty than admit, without further investigation, their marsupial character.

Mr. F. M. Balfour read a paper on 'Some Points in the Development of Elasmobranch Fishes.'

Professor Huxley, said it might appear strange that it should be thought worth while to spend so much time upon such a question as the mode of origin of the young dog-fish; but it should be remembered that the dog-fish belonged to the same great group of animals as man, and all the points raised in connection with the former might be brought to bear on the origin of the latter.

Professor Redfern then read a paper on the influence of food, and the methods of supplying it to plants and animals. Plants, he said, entirely uninfluenced by any but physical conditions, had long since taught farmers, and gardeners especially, that they must not only have abundance of food, but that they must have it in a condition in which they can readily make use of it. In proof of this he need

only refer to the known necessity for the regular use of highly nutritious liquid manure in the cultivation of perfect roses, and to the care the agriculturist had learned to take in the application of the proper kind of artificially prepared manure for each crop, and in its use in a form in which the plant could most easily absorb and apply it. It was many years since that Mr. Ward gave a beautiful illustration of the influence of food on plants. He found a perfect specimen of the common centaury half an inch high, with one or two pairs of most minute leaves and one flower, on the bare chalk at the border of a wood; on tracing it into the open parts of the wood it became a glorious plant, four or five feet high, and covered with hundreds of flowers. He (Professor Redfern) wished to show that it was not only important to supply plants with food, but to do this so that they could easily appropriate it, otherwise the supply would be lost and wasted. He had brought with him a series of specimens of common rape, which would speak for themselves. The largest specimen measured five feet six inches high; they branched freely from the ground upwards at intervals of a few inches; their large leaves, thick and fleshy, measured fourteen inches by six inches, and their flowers once covered the plants with their brilliant yellow colour. The middle-sized specimens measured five feet two inches high, but for three feet from the ground they had no branch at all; their leaves were very small, and the plants were little more than a fibrous stem, with a few flowers at the top. The smallest specimens were only three feet high, having a few leaves not an inch long by $\frac{3}{10}$ ths of an inch broad, and a few flowers at the top entirely useless for any purpose whatever. Other specimens of an essentially similar kind were grown on another spot of ground, under circumstances essentially similar. Of these specimens a large number only measured fifteen inches high; they were furnished with a few almost linear leaflets and a few flowers at the top. Yet the larger specimens grown on this ground were five or six feet high, covered with large spreading branches, furnished with abundance of leaves, yielding a very large amount of good fodder compared with the amount of surface covered by them. With regard to the roots, those of all the poorer plants were straight, small, and but little branched; while those of the well-developed plants were thick, branched, and extended on one side only. For from four to six feet distant from the edge of the plot of rape on each side, the ground had been trenched two spades deep for planting with trees and shrubs, and a quantity of bog-earth with sand and manure had been mixed with it, the manure having been put at the bottom of the trench, and the mixed bog-earth and sand half way down. The only well-developed plants grew near the edge of this trenched ground, and their one-sided roots spread into it for two feet, exactly in the position occupied by the mixed bog-earth and sand. There were only occasional smaller plants at this part, and the roots of every one of these were straight, short, and but little branched. They, in short, had not discovered that there was soft and spongy ground within so short a distance, ground in which their roots might have revelled in growth like those of their neighbour giants, if they had been equally fortunate in finding their way thither. None of the thick long roots on the trenched side of the plants penetrated deeply into the trenched ground. It was the loose and spongy condition of the soil that had

attracted them, and not the manure, for not one root had attempted to penetrate to the depth of the manure—all had been content with the position of the mixed bog-earth and sand, thus affording an absolute demonstration of the necessity of attending to the mechanical of the soil as well as to its containing a sufficiency of the materials which plants needed for food. His plants of rape had abundant nourishment in their immediate vicinity, but they could not avail themselves of it, the soft spongioses of their roots being unable to penetrate the tough clay, which a great amount of labour had failed to render porous enough for roots of any kind to enter to any considerable extent. Such was exactly the condition in which many persons were who had never applied their intelligence to the selection of their food or to the methods of taking it. There were few social problems more important than how to acquaint the wife of the labourer or artisan, or even the wives and servants of the middle classes, how to expend a fair share of their income upon food to the greatest advantage, and how to prepare it without destroying its nutritive properties. A savoury dish of meat was often prepared by mincing or cutting the meat into small and more or less cubical blocks. It was then stewed, or more frequently boiled; the outer surface of each little block had its albumen firmly coagulated, and the whole was converted into about as indigestible a mass as could well be imagined, the high-priced and highly nutritious meat having been destroyed for the purposes of nutrition, and the action of the digestive organs probably injured for some time to come. Or good and valuable flesh-meat was subjected to the process of salting, which first of all abstracted the juices of meat, and then hardened the fibres, so as to destroy or greatly deteriorate its digestibility. No doubt it was convenient to have a hardened dry mass of meat incapable of much change for months, and ready to be used for the purpose of filling the stomach and effectually satisfying the appetite; but these were not the purposes for which food was intended to be used. It ought to be capable of supplying the waste of the body, and of being easily converted into heat and motion. If it failed in these particulars it would also fail in nourishing the brain, and aiding in the evolution of intelligence, and thus intellectual and bodily power was lost to the community, and deterioration of race was promoted. His colleague Dr. Gordon said that he recollected running races, putting stones, wrestling, and other athletic exercises being the favourite amusements of the sons and servants of the farmers in the County Down. Now nothing of the sort was heard of. These young men found a short day's work almost too much for them, and at the end of it they were to be seen lying about indulging in idle conversation. Coincidentally with this they imagined themselves the equals of their masters and mistresses, and that the healthful oatmeal porridge and butter-milk twice daily, with beans and bacon for dinner, was too strong and coarse; they insisted on more delicate fare, and demanded a supply of tea and white bread. They were unconscious that persons in their position but a few years ago possessed amazing vigour, and performed twice the amount of labour with greater ease, and when the day's work was over, actually revelled in the display of surplus strength which nothing but their better and more rational diet could have yielded them.

Dr. Pye-Smith said that there was no line between the animal and vegetable kingdom, and the same

laws applied to both, as shown by Dr. Redfern's paper.

Dr. John Moore said that in no part of the kingdom was Dr. Redfern's advice more needed than in Belfast, where a great amount of suffering, loss of wages, and degeneration was occasioned by deficient food and defective arrangements for its preparation. He referred especially to the large amount of tea (often prepared over night) consumed by the working classes. He believed that half of the disease among the mill-working population of Belfast was due to these causes.

A paper was read by Mr. E. R. Lankester on the the Development of the Eye of Cephalopoda.

This was followed by a paper by the President (Professor Redfern) on 'The Effects of Ozone on the Animal Economy.' He gave an account of a number of experiments with animals made to breathe oxygen mixed with ozone, and others made to breathe pure oxygen. The general results of these experiments were as follow. The respiration of oxygen with a 24th part of ozone for a very short time, say twenty seconds, is certainly fatal. The same gas, when resolved again into oxygen, is comparatively harmless, even when respired for long periods. Death from the ozone is not due to a closure of the glottis but to a congestion of the lungs, with emphysema and distension of the right side of the heart with a fluid or coagulation of blood, frequently attended by convulsions. If the ozone be respired in a dilute form, animals become drowsy and die quietly from coma, the condition of the lungs being the same, except that the emphysema is less marked. Animals that have respired oxygen more than twelve hours will now and then die suddenly from the formation of coagula in the heart, even after they have been in good health for some days.

LEFORT ON THE TOXICOLOGICAL INVESTIGATION OF PHOSPHORUS.

A problem of considerable importance was recently brought by a magistrate before the Society of Legal Medicine in Paris; it was this. In absence of the least trace of free phosphorus in suspected matters, and also of every characteristic morbid symptom, such as steatosis of the liver, may experts conclude—from having observed an abnormal quantity of phosphoric acid, or of ammoniaco-magnesian phosphate, in the substances subjected to chemical analysis—that there has been poisoning by phosphorus? A committee was appointed to examine the point, and the following is an abstract of the report presented by M. Lefort.

1. *Phosphoric Acid.*—At the time when poisonings by phosphorus began, it was supposed that, though the suspected matter might not present the poison in the natural state, the presence of phosphoric acid might be regarded as proof of crime. This view is now rejected by the majority of chemists. Two toxicologists of high authority, MM. Tardieu and Roussin, pronounce against it. They say, 'All our different organs and tissues, all our common articles of food, contain, it is known, very considerable proportions of alkaline and earthy phosphates, and especially phosphate of soda and phosphate of lime. The mere presence of phosphoric acid proves nothing.'

This precept is of the greatest importance, and experts should never forget it, for it is the expression

at once of prudence and of truth; as we hope to show from experiment.

It is worthy of remark that most chemists who have inferred poisoning by phosphorus from the existence of phosphoric acid have not taken into account that, as time progresses after death, certain organs become acid, from having been neutral, or even alkaline, during life; still less have they assured themselves as to the cause of this acidity. We know, however, that when organic substances begin to decompose, the first result observed is the formation of one or several organic acids at the expense of the sugar and the animal dextrine disseminated in the principal parts of the economy, as the liver and the muscles. It is only later that ammoniacal products appear, and that these matters become alkaline.

But this is not all. If, from the various organs, we come to the food-supply of the stomach and the intestines, we find conditions still more favourable to the formation of those organic acids which medico-legal analysis may altogether confound with phosphoric acid, more or less impregnated with phosphates. We shall see that the muscular flesh of animals contains less of animal phosphates than bread; but the latter, undergoing, in the stomach, the series of phenomena of digestion, and then of fermentation, produces, from the starch of which it is largely composed, relatively considerable quantities of an organic acid, which is, without doubt, lactic acid.

One understands then, how experts have often ascertained an exceptional acidity of some matters contained in the stomach, such as bread. But it is another thing to prove that this acidity arises from a mineral acid, such as phosphoric acid, rather than from a biphosphate or an organic acid like lactic acid, which may be fixed in large proportion in the muscular tissue. Certain experts know this so well, that they generally pass in silence the processes they have adopted for separating distinctly the phosphoric acid from the organic acids, lost, in some sort, in the animal substances more or less advanced in decomposition. The fact is, that these acids accompany each other in all the chemical operations to which they are subjected in order to isolation; so much so that still, notwithstanding the numerous works undertaken by savants of the first rank, the nature of the compound to which gastric acid owes its acidity is unknown; this being attributed by turns to lactic acid, hydrochloric acid, and biphosphate of lime.

Generally, criminal poisonings with phosphorus are effected with less quantities of phosphorised preparations than suicides by this poison. On the other hand, the first care expended on individuals who have been poisoned has the effect of eliminating, by vomiting and purging, a very considerable proportion of phosphorus more or less in the state of a simple body. It is, then, only the quantity of poison absorbed, and spread throughout the system, that experts have to isolate in the state of phosphoric acid. Some authors, Reveil in particular, suppose that it is possible to determine the quantity of phosphorus contained in a known weight of suspected matter, comparatively with the phosphorus which may be found in an equal weight of the same organ not poisoned. Your committee cannot sufficiently protest against such an affirmation; because it may lead to results much to be regretted.

Indeed, for this to be admissible, it would be necessary to suppose that the proportion of normal phosphates is absolutely the same at all ages of life, in all the organs, and that it is the same not only

with man, but also with the aliments which serve for his habitual nourishment. Now this is not the case, as the following experimental data prove.

M. Verdeil has analysed the blood of a certain number of carnivorous animals and of herbivorous animals, and has ascertained that the blood of the former is much richer in phosphates than that of the latter. Thus, while the blood of man gave 9·74 of phosphoric acid per 100 parts of ash, ox-blood furnished only 3·40 for the same weight.

We have determined the proportion of phosphoric acid in the muscular flesh of a patient who died in the Hospital de la Pitié, and found in it 0·179 per 100 grammes of fresh matter. The muscular flesh of another subject who died rapidly from an accident furnished 0·333 grammes of combined phosphoric acid per 100 grammes of flesh-tissue, *i.e.*, nearly double. The liver of this same individual contained 0·288 grammes of phosphoric acid also in the state of phosphates. Lastly, the stomach of a woman who died in a very few days from pneumonia, contained 0·186 grammes of combined phosphoric acid for the same quantity of fresh substance.

We may further cite as proof of the extreme variation of phosphates in the animal economy the experiments of Dr. Bence Jones, who found that in 1,000 grammes of urine the earthy phosphates reached before meals 0·21 to 0·75, and after, from 0·97 to 1·91; in the same quantity of urine the alkaline phosphates varied before meals, from 6·5 to 8·1, and after meals, from 4·72 to 6·67.

M. Couerbe long since discovered that the brain of idiots and old people was always less rich in phosphorus than that of healthy adults. On the other hand, M. Bourgoïn has shown that the proportion of phosphorus in the brain is never the same in different individuals, and that even in the white and the grey matter of the brain this quantity may vary by nearly a third.

According to M. Roucher (one of the committee) 100 grammes of matter from the following organs of a subject dead from atrophy of the liver, contained of phosphoric acid (free or combined)—liver, 0·517 grammes; lungs, 0·205; kidneys, 0·274. The same organs of another subject who died poisoned with phosphorus, furnished—liver, 0·493 grammes; lungs, 0·274; kidneys, 0·339. Thus the liver of the subject poisoned by phosphorus furnished to analysis less phosphoric acid than that of the individual who died from atrophy of the liver.

It is true that the lungs and kidneys of the second contained more phosphoric acid than the same organs of the first. But who could affirm with justice that there had been ingestion of phosphorus, because the lungs and the kidneys of an individual said to have been poisoned contained six to seven centigrammes of phosphoric acid more, for the same weight of substance, than those of another individual who died under normal conditions? The mode of analysis adopted in the circumstances could not even guarantee this difference. On the other hand, it should not be ignored that the system contains, under the name of protagon, a complex animal matter in which phosphorus is in the state of a simple body, but molecularly united with oxygen, carbon, nitrogen, and hydrogen.

We have submitted to analysis a certain number of organic matters, more especially utilised for the food of man; and the results are these.

One hundred parts of fresh food contained, of phosphoric acid—

| | Grammes. |
|---|----------|
| White bread (crumb and crust) | 0'049 |
| Beef (fillet) | 0'395 |
| Veal do. | 0'374 |
| Pork do. | 0'430 |
| Carp (muscular flesh of back) | 0'345 |
| Pike do. do. | 0'465 |
| Ray do. do. | 0'514 |
| Mackerel do. do. | 0'533 |
| Brain of ox (grey and white substances) | 0'502 |
| Brain of sheep do. do. | 0'760 |

We call to mind that Dr. William Marcet has communicated analyses of muscular flesh of ox, taken from various subjects, in which the proportion of phosphoric acid varied from 0'404 to 0'438 per 100 grammes of fresh substance.

These examples serve to show how variable is the proportion of phosphates in the principal aliments of man, and how difficult it is, not to say impossible, to pronounce upon the part belonging to the phosphoric acid of these normal phosphates, and the part of phosphoric acid formed by the phosphorus introduced criminally. Toxicological chemistry should carefully record these facts, for they represent the safeguard of justice. We say, therefore, in concluding, that *the proportion of phosphoric acid found in suspected matters subjected to chemical analysis is not a convincing proof that there has been poisoning by phosphorus.*

2. *Ammoniac-magnesian Phosphates.*—Is the presence of a comparatively large quantity of crystals of such phosphates in putrefying animal matters the indication of an ingestion of phosphorus during life?

The proportion of these crystals has always been subordinated to that of phosphates, whether normal or accidental. Whenever a dead body, buried some time, is in active decomposition, the large quantity of carbonate of ammonia produced, the magnesian salts of the organic matter, or even those which are brought by water of the grave, and lastly, the normal phosphates, produce by their special affinities ammoniac-magnesian phosphate, which crystallises more easily the more ammoniacal the medium in which it is formed. It is, however, to the abundance of these crystals in suspected matters, that, in some medico-legal investigations, recourse has been had for concluding that poisoning by phosphorus has taken place.

Your committee rejects absolutely this evidence, because it is not convincing in the least. We have only to cast our eye over the preceding table to be convinced that the quantity of normal phosphates is more than sufficient to produce in animal matters, that are in course of decomposition, crystallised ammoniac-magnesian phosphate, very visible to the naked eye, and still better with the microscope.

Consider *e.g.* that the muscular tissue contains normally, and on an average, four thousandths of combined phosphoric acid. If, by calculation, we convert the whole of this acid into ammoniac-magnesian phosphate, we find that there may have been formed 13'80 grammes of this salt, easily distinguished by its great insolubility and the regularity of its crystallisation; and yet we are supposing that the waters of infiltration, which very often permeate the graves of cemeteries, do not bring with them phosphates which might increase those of the bodies.

What, then, is the share to be assigned to normal phosphates and to phosphates arising from ingestion of phosphorus? It will not be forgotten that phos-

phorus is a poison of great energy, and that it can only, in general, be administered in the smallest quantity, because its special characters (odour and phosphorescence) soon reveal a criminal intention; lastly, that it is rather a poison of contact and absorption than a poison of localisation, and consequently the system cannot long accumulate it in the framework of the tissues. Every one knows, besides, that the absorption and elimination of phosphorus are so prompt, that the first urine of the individual poisoned in this manner is luminous, and yet death may not occur for seven or eight days after ingestion of the poison.

Such are the considerations which lead us to conclude that neither the presence, nor the quantity of phosphoric acid and crystals of ammoniac-magnesian phosphate in suspected matters, can be considered as proof of poisoning by phosphorus in the natural state.

ALEX. B. MACDOWALL.

RICHARDSON ON THE VALUE OF HIGH POWERS IN THE DIAGNOSIS OF BLOOD-STAINS.

Two questions are often asked of the medical jurist: 1, is a given stain blood? and 2, if blood, from what animal is it derived? To the first question, thanks to micro-spectroscopy, we are able to give an unhesitating reply; to the second we are silent. Any attempt at laying the foundation for a reply to this question, we hail with satisfaction. Such an attempt is made by Dr. Joseph G. Richardson, of the University of Pennsylvania, in a paper published in the *American Journal of Medical Science*, for July. But we should be sadly in error if we regarded Dr. Richardson's work as complete.

Dr. Richardson says that, by the use of very high powers, the microscope will answer the question from what animal is the blood derived? We may urge that the difference is too minute to render the test of use, when the life of a man depends upon the opinion; but Dr. Richardson says, as a shot-dealer distinguishes at a glance the different numbers of shot, so a skilful microscopist ought to recognise different sizes of blood-corpuscles under his instrument. Dr. Richardson, however, denies that the differences between the sizes of the different blood-corpuscles are minute when measured by the one-fiftieth inch; with such a power the human red corpuscle appears about one inch and one-eighth in diameter; and he asserts that with such a magnifying power, mistake to the skilled microscopist is impossible. All this is very well. Dr. Richardson however, first alleges that the difference in the size is not minute, and then argues how often evidence has been given on a minute fraction of a grain of arsenic which no balance can weigh. But two wrongs do not make a right. If the reaction of arsenic be not distinct by more tests than one to the unaided vision, we hold that no toxicologist has a right to assert its presence as a cause of death.

But again: the measurements of the blood-corpuscles of an animal show great variation. This irregularity, it may be said, renders the mere measurement as a decided test unreliable. To this question of irregularity due to varying sizes, Dr. Richardson replies: 1st, that the variations in the size of fresh blood-corpuscles is exceedingly slight, and he quotes measurements in proof; and 2ndly, that it is only in dried corpuscles variation is notice-

able, and this Dr. Richardson calls 'a pathological change.' But Dr. Richardson seems to forget that the medical jurist is not often called to examine *fresh* blood, and that he is very often required to examine *old* blood. Admitting, therefore, the fact which Dr. Richardson asserts (and we cannot just now prove or disprove it), that the source of fresh blood can be recognised by this high microscopic power, with the blood-stain dried and shrivelled, as the medical jurist usually has it presented to him, Dr. Richardson seems to allow it may possibly be imperfect.

And again, it must be urged that, when a man's life depends on the opinion of the microscopist, it should be something more certain than the calculation 'of a blood-corpuscle's ratio of contraction by drying.' But Dr. Richardson replies to this, by arguing that a human red corpuscle is very much larger than that of an ox, or horse, or pig, or goat, etc. 'If, therefore (says Dr. Richardson), a human red corpuscle did contract so as to be mistaken for that of an ox (and he admits that it may), he says such evidence would only mislead us into assisting in the acquittal of a criminal, and could not betray us into aiding to convict an innocent person.' We confess to being astonished at such an assertion. It might be (such cases have occurred) that the discovery of the blood of an ox or horse would, if it did not hang a man, be strong evidence against him in a trial, as well as the discovery of human blood. Surely, therefore, Dr. Richardson admits that mistakes may occur even with his high powers.

Dr. Richardson further asserts that the cell-wall of a red blood-corpuscle is nearly or quite inelastic, and hence cannot expand. Therefore, he points out, the red corpuscles of an ox cannot expand when moistened to the size of a red human corpuscle. He admits, however, that a change of shape does produce an apparently slight increase in size. Again, he argues from this that a criminal is safe. We confess that we cannot see it. If the blood-corpuscle of an *ox* cannot *expand* (and it may apparently do so), the blood-corpuscle of a *man* may *contract*. The source of fallacy is the same. And we are at a loss to see why, because a corpuscle of an ox cannot expand to the size of a red corpuscle of a man, although the red corpuscle of a man may shrink to the size of a red corpuscle of an ox, 'a mistake can never occur which will lead to the punishment of an innocent party.'

Dr. Richardson gives numerous illustrations of measurements and successful determinations of the source of blood stains submitted to him. In moistening the blood-stains, Dr. Richardson advises the use of a glycerine solution, and that the part of the stain used for the examination should be the edges rather than the central portion, because from the centre numerous fibrin filaments are more likely to be obtained, and they interfere with the investigation by forming a network around the cell walls, and so confusing the outline.

Dr. Richardson's paper is interesting, but we are afraid the question often put, 'What is the source of the blood in a stain?' must still go unanswered. In questions where capital punishment hangs on scientific evidence, that evidence must be of no doubtful or questionable nature; and we entirely fail in endorsing Dr. Richardson's opinion which he so confidently states, that 'We are now able, by the aid of high powers of the microscope, and under favourable conditions (!) to positively distinguish stains produced

by human blood from those caused by the blood of any of the animals just enumerated,* and this even after the lapse of five years from the date of their primary production.'

ANATOMY AND PHYSIOLOGY.

MARCEY ON THE NUTRITION OF ANIMAL TISSUES.—In a pamphlet (pp. 52) giving an account of an experimental inquiry into the nutrition of animal tissues, Dr. Marcey arrives at the following conclusions. 1. The physical constitution of a muscle resembles that of a jelly. 2. In all tissues there are three classes of substances: (a) those forming the ripe tissue, which are insoluble in water; (b) those constituting the nutritive material, soluble in water, and colloid; (c) the effete products, soluble in water, crystalloid and diffusible. 3. The nutritive material and ripe tissue have the same chemical composition. The mature tissue is merely the nutritive material in an organised form, the change from one to the other being purely morphological. 4. In muscle, the whole of the phosphoric acid is eliminated in the form either of a neutral tribasic phosphate or a pyrophosphate of potash. At the same time, some phosphoric acid and potash are present in flesh which are not in the proportion of a phosphate, and take part exclusively in the formation of ripe tissue. 5. The albuminous constituents of muscle appear to be eliminated as kreatine, kreatinine, and other crystalloid substances. 6. Muscular tissue takes from the blood more potash than it requires for its formation, the excess being necessary to the elimination of phosphoric acid by converting it into a crystalloid phosphate. 7. The nutrition of lung-tissue appears to differ from that of muscles by being much more rapid, for it contains a much larger proportion of nutritive substance, and much less waste than muscular tissue. 8. Potash is eliminated from the lungs in great measure as crystalloid carbonate, instead of in the form of phosphate, as it is in muscles. This is due to the carbonic acid in the lungs. 9. The proportion of phosphoric acid and potash is different in wheaten flour, potato and rice, but the proportion of total to colloid phosphoric acid and potash is very nearly the same in each. 10. Muscles in phthisis differ from the normal in containing less nutritive material and mature tissue, rather more water, and a much higher proportion of chlorine and soda. 11. In phthisis, the waste of muscles occurs in the normal way, and the potash and phosphoric acid present in the effete products are in exactly the right proportion to form a pyrophosphate. 12. The emaciation in phthisis appears due mainly to the blood not being in the proper condition to supply nutritive material to muscular tissue. The damp or wet state peculiar to muscles after death from phthisis appears to show that their colloid state is somewhat deficient in that disease. 13. The tubercular or adenoid formation in pulmonary tissue actually undergoes nutrition, and is consequently a growth, the phosphoric acid of potash being apparently eliminated, as in the case of muscle, under the form of a crystalloid phosphate. The nutrition of the abnormal growth accounts for the almost invariable absence of any smell of decompo-

* Viz., the pig, $\frac{1}{3}$ in.; the ox, $\frac{1}{4}$ in.; the red deer, $\frac{1}{5}$ in.; the cat, $\frac{1}{6}$ in.; the horse, $\frac{1}{8}$ in.; the sheep, $\frac{1}{10}$ in.; the goat, $\frac{1}{12}$ in.; the average of the human corpuscle being $\frac{1}{15}$ in.

sition when a *post mortem* examination is made shortly after death from phthisis. 14. The softening of tubercular substance appears due to a loss of colloid power. It can hardly be due to an increase in the proportion of water, as softening tubercle contains very little more water than healthy lung. 15. There appears to be no increase of fat in tubercle, the mean being 2.14 per cent. in healthy, and 1.95 in diseased lung-tissue. The diseased lungs, however, contain more water, and the proportion of fat in their dried residue is slightly greater than in the dried residue of healthy lungs. 16. In nature, soluble matter is undergoing perpetual transformation, passing in rotation from the crystalloid to the colloid, and again from the colloid to the crystalloid condition. Chloride of sodium alone appears to be an exception to this rule.

T. LAUDER BRUNTON, M.D.

THOMSON ON THE DECOMPOSITION OF EGGS.—In a paper lately read before the British Association at Belfast, Mr. William Thomson said that researches on this subject were commenced by the late Dr. Crace Calvert and himself about the beginning of October, 1870, and extended over the following year and a half. From numerous experiments he drew the conclusions that whole eggs could only be attacked by one, two, or all, of three different agencies of decomposition. The first, which he termed putrid cell, is capable of being developed within some eggs, no matter how effectually their shells be protected by varnished coverings from the spores floating in the atmosphere. It is generated from the yolk. In some cases the yolk begins to swell and absorbs most of the white; in others the yolk bursts, and its whole substance becomes thoroughly mixed up with the white; and in others again it begins to change slightly, and then gives off minute cells into the white, rendering the white turbid; but in all cases where this takes thorough hold of the contents of the egg, true putrefaction commences, and the albumen emits a putrid smell. The minute granules or cells of the healthy yolk, when this decomposition commences, assume a morbid vitality; they grow large, and become filled with small cells; each large cell then bursts, and the smaller cells take independent existence. These cells are the bioplasm of the yolk, which, had the egg developed into a chicken, would have gone to form its flesh, bone, and tissues. These cells, under their morbid vitality, absorb oxygen, and liberate carbonic acid gas. Two eggs had their shells well varnished over with shell-lac, and were set aside on a shelf for one year, and both then opened. One appeared as fresh as on the day when it was set aside, but when the other was struck with the point of a knife to open it, the pressure of gas contained within the shell burst out, and scattered parts of its contents in all directions. The next germ of decomposition—the vibrio—appears under the microscope like a small rigid worm which swims about. These animalcules are constantly found floating about in the atmosphere, but never penetrate into the contents of an egg if the shell be kept dry, but if the shell be moistened or wet, the dried bodies of these animalcules develop in that water, assume much vitality, and then penetrate the shell and set up putrefaction. Eggs were placed in fluids swarming with different animalcules, some like cork-screws, which swam by quickly turning round; others which appeared under the microscope like flukes, but which really had the form of an egg; some with one, some with two feelers, which swam by switching those

feelers into a quick serpentine motion in front of them. These, however, were not able to penetrate the shell of the egg. The third is the fungus decomposition. The spores of this fungus are found everywhere floating in the atmosphere. They settle on the shells of eggs placed in stagnant atmospheres, and send myriads of filaments through the shell in all directions, sometimes binding all sides of the shell together, in all cases converting the white into the consistency of a strong jelly, and often the filaments grow in such immense numbers as to make the whole contents appear like a hard-boiled egg. This fungus acts on the air exactly like animalcules, absorbing oxygen and liberating carbonic acid gas.

SLAVJANSKY ON THE DEPENDENCE OF THE MEDIUM CURRENT OF THE BLOOD ON THE DEGREE OF EXCITATION OF THE SYMPATHETIC VASO-MOTOR NERVES.—Kronid Slavjansky (*Arbeiten aus der phys. Anstalt zu Leipzig*, 1874, and abstract in *Centralblatt für Chirurgie* no. 19, 1874) has made a large number of experiments upon the inferior vena cava and carotid artery of young dogs and rabbits, to ascertain whether the rapidity of the whole blood-current was increased or diminished when a large number of sympathetic and vaso-motor nerves were stimulated simultaneously. Simultaneously with the estimation of the rapidity of the volume of blood flowing out of the inferior vena cava, the blood-pressure was measured in the carotid. The inferior vena cava was employed for the experiment, because its blood passes through muscles, bones, skin, and the intestines, *i.e.*, through organs which stand in the most different relations to the vaso-motor nerves. The results obtained from the vena cava were controlled on the carotid by two series of experiments. The blood caught from the carotid was measured in the apparatus of Tappeiner (Ludwig's *Arbeiten*, 1872), whilst a mercurial manometer was placed in the carotid of the opposite side.

From observations on the spinal cord of curarised animals, Slavjansky, obtained the following results.

1. The quantity of blood which passes through the heart varies with the stimulation of the spinal cord; after division of the spinal cord it sinks below the normal, after stimulation of the same it increases from five or six to ten times.

2. With this increase of the blood flowing through the heart, on stimulation of the spinal cord, *i.e.*, of the sympathetic vaso-motor nerves, the pressure in the aortic system also rises, because the contents on one part of the vascular system (inferior vena cava), are driven by stimulation of the nerves which cause contraction of the vessels into the aorta, and so the contents and pressure are here increased.

In order to control the correctness of these results, the vascular area, which was closed, or at least lessened by stimulation of the sympathetic nerve-fibres, was artificially shut off by ligature of the intestinal arteries and of the portal vein; and on stimulation of the splanchnic nerve, the following results were obtained.

1. Ligature of the cœliac, and of the superior and inferior mesenteric arteries, led to obstruction to the aortic current, and therewith obstruction of the flowing off of blood in a wide area. The rapidity of the quantity of blood flowing in the vena cava is somewhat diminished, the pressure in the aortic system increased.

2. Ligature of the portal vein produced widening

of the current area of the vessels of the abdomen, and filling with blood; the pressure in the aortic system was diminished until death; and there was diminution of the volume of blood flowing.

3. Stimulation of the splanchnic nerve produced closure of the abdominal arteries and emptying of their contents. Pressure in the aortic system was increased, and there was an increase in the volume of blood flowing.

WILLIAM STIRLING, D.Sc., M.B.

CLARK ON CERVICAL RIBS.—In the July number of the *Glasgow Medical Journal*, Mr. Clark records a case of cervical ribs, in a subject of which neither the sex nor probable age is mentioned. What appeared to be the first rib on the left side was abnormally broad, being one inch and a half in length at its sternal end. There were only eleven ribs on this side, while on the right side the number was normal. With the vertebra immediately above that to which the abnormally broad rib was attached, and on the same side, was articulated a rudimentary rib, one inch and a half in length, having a well-marked capitulum and tuberculum, attached by complete joints to the centrum and transverse process of the vertebra. This rib corresponded in position to an unusually narrow but complete rib on the right side, having a well-defined scalene tubercle, lying betwixt deep grooves for the passage of the subclavian vessels, thus contrasting with its fellow on the opposite side, on which these characteristic landmarks were but faintly defined. It was discovered, on closer investigation, that the rudimentary left upper rib, and the upper rib on the right side which was so distinctly ridged and furrowed, both took origin from the seventh cervical vertebra, and must therefore be regarded as true 'cervical' ribs. Unfortunately, before a close investigation of the ribs was made, the lumbar vertebræ, together with the sternum and clavicles, had been removed; for it would have been interesting, seeing that out of twelve ribs present on each side only eleven were thoracic, to have ascertained whether the number of lumbar vertebræ had been, in compensation, raised to six. Mr. Clark quotes, as parallel to his case, that of a Chinese, recorded by the late Mr. Holmes Coote, in whom the ribs were attached to the twelve middle vertebræ (thoracic) of the trunk, six cervical vertebræ being left free above, and the same number of lumbar vertebræ below. [A fair proportion of cervical ribs support the subclavian vessels, and have been thus diagnosed even during life. Halbertsma went so far as to lay down a formula that a cervical rib 5·6 centimètres and more in length, will support the subclavian artery, while one shorter than 5·1 centimètres does not support the vessel. Professor Gruber not only regards this as untenable, but asserts that the grooving of the upper surface of a cervical rib is due as much to the lower roots of the brachial plexus as to the pressure of the subclavian artery. See further, Turner 'On Supernumerary Cervical Ribs,' *Journ. of Anat. and Phys.*, Nov. 1869; Gruber 'Ueber die Halsrippen der Menschen,' *Mém. de l'Acad. Imp. des Sciences de St. Pétersbourg*, tom. xiii.; Henle, *Knochenlehre*, s. 72.—*Rep.*]

COLLINS ON ACCESSORY LOBES OF THE HUMAN LUNGS.—Dr. Collins describes (*Transactions of the Royal Irish Academy*, vol. xxv.) the occurrence of an accessory pulmonary lobe in a male, about fifty years old, and reviews the literature of the subject.

This structure, of which a figure is given, occupied the angle between the upper portion of the right lung and the posterior part of the root of the same. It was pyriform in shape, had a broad peduncle, and lay upon the bodies of the five upper dorsal vertebræ in an accessory pleural pouch, which communicated with the general pleural cavity only around the peduncle. The trachea was completely separated from the spinal column by the pouch; and the azygos vein, at the head of the fifth rib, after receiving the superior intercostal tributary, instead of arching over the bronchus behind the pleura, entered the margin of the pleural fold. This latter, moreover, covered in the accessory lobe and isolated it completely, save at the peduncle, from the upper portion of the lung.

The earliest recorded abnormality of a similar nature was that laid by Wrisberg before the Royal Society of Göttingen in 1777; and since then Rokitsansky, Bouchaud, Chiene, Cleland, and Wenzel Gruber have directed attention to the same subject. Seven cases in all have been described, Wrisberg's being the only one in which the accessory lobe was on the left side.

Dr. Collins feels inclined to give assent to Dr. Cleland's theory, that early in foetal life, from such cause as a slight adhesion of the lung to the wall of the thorax, the azygos vein, when drawn downwards by the descent of the heart so as to be made to run at a right angle to its originally transverse direction, dragged down and became enwrapped in a fold of pleura, thus deeply notching the lung instead of slipping behind both structures.

As regards certain other accessory lobes described by M. Pozzi and Professor Rektonzik, probably homologous with the 'lobus impar' which occurs in lower mammals from the quadrumana downwards, Dr. Collins would consider such 'as merely examples of that redundant lobulation not unfrequently seen in other viscera, and as not meriting the title or consideration of special accessory lobes.'

J. C. GALTON.

EBNER ON THE ACINOUS GLANDS OF THE TONGUE.—In a pamphlet recently issued, Herr von Ebner describes a series of small glands chiefly situated near the back of the tongue in man and mammals. They are best seen in guinea-pigs, and consist of an excretory duct lined by a single layer of epithelium and opening out into a series of alveoli resembling those of the pancreas. The fluid secreted is peculiar in containing no mucin. The glands have accordingly been termed *serous* glands.

HUIZINGA ON ABIOGENESIS.—In a paper published in *Pflüger's Archiv* (Band viii.), Dr. Huizinga opposes the statements of Samuelson and Burdon Sanderson, and adheres to his own previously expressed views, which are in favour of the origin of organisms; without the co-operation of pre-existing organisms, in other words, in favour of spontaneous generation. He objects to the employment they made of hermetically sealed tubes containing but a small amount of air, a condition which is unfavourable for the development of life. He himself used septa and corks, if they may be so called, of porous earthenware. He exposed the fluids with which he experimented to a temperature of 212° Fahr., or a little above, which, he believes, killed all organisms and their germs. Notwithstanding this, he found bacteria in a mixture of potassium nitrate, magnesium

sulphate, calcium phosphate, starch, peptones, and grape-sugar. When such a mixture was exposed to a temperature between 220° and 230° Fahr., however, no bacteria appeared.

PATHOLOGY.

BENEDIKT ON LYMPHORRHAGIA ('GRANULAR DISINTEGRATION' OF LOCKHART CLARKE).—Professor Benedikt (*Mittheilungen des Aertztlichen Vereines in Wien*, 1874, Band. iii. Nr. 10) refers in the first place to a previous communication of his own, on the conditions of the lymphatics in inflammation, in which he showed that the presence of the so-called 'inflammatory nuclei' depends upon the accumulation of lymph-corpuscles which have undergone a chemical change. To clear the way in the discussion of the present topic, Dr. Benedikt proceeds to consider the questions, 'What is lymph?' and 'Whence come the lymph-corpuscles?' To the first question he gives the obvious reply, 'Lymph consists of the contents of the lymphatic vessels.' To the second he answers, with equal precision, that the lymph-corpuscles must either be formed in the vessels or drawn thither from without. In inflammation, which is essentially an exaltation of normal processes of circulation and nutrition, there is no doubt that the white corpuscles pass by determinate routes into the lymphatics, and suffer certain chemical changes.

In the essay under notice, the author applies his views as to the nature of the lymph, and its vessels, to the elucidation of the pathological condition of the spinal cord, which has been designated by Dr. Lockhart Clarke, 'granular disintegration.' Great as is the authority of the distinguished English anatomist, observes Dr. Benedikt, he is perhaps one of the least read as regards his *original* writings [On the continent only?—*Ref.*] Often as the term 'granular disintegration' is quoted, but few authors seem to have consulted the original essay. In Germany, adds Dr. Benedikt, this same lesion has been described by one author, without any apparent suspicion that it is identical with that described by Clarke.* The description there given will serve for the same changes as observed by the author in a case of paralytic dementia. To follow Dr. Clarke's description, the morbid deposit is seen around vessels, and, under the microscope, is seen to present a delicate, transparent, and very granular aspect. The granular mass is thicker towards the centre, becomes punctiform, and is marked off from surrounding structures by a sharply defined margin. Within, the remains of broken fibres and vessels may be seen, and in the centre a circular opening may be found. Around it were crowded numbers of amyloid bodies.

Dr. Benedikt states that, in order to avoid misunderstanding, he submitted his preparations to the inspection of Dr. Clarke, who admitted their identity with the appearances above described. The deposit which the author describes as being contained both within and without the adventitia of the perivascular spaces, included so-called inflammatory nuclei in great numbers. Dr. Benedikt particularly points out that the deposit, both within and external to the adventitia, is of the same nature, and derived from the same source. Arndt, the author adds, has also

admitted the relationship of this deposit to lymph, although he considers the perivascular spaces, according to Golgi's process of injection, to be artificially produced.

The next point discussed is, how the deposit arrives outside of the adventitia. Doubtless, Dr. Benedikt remarks, either from rupture of the membrane, or from transudation without rupture, more frequently under the former condition; it is often found in inflammation that the nuclei in the lymphatics are not separated by any membrane from the perivascular space. The adventitia is dissolved, and disappears in the hyaloid degeneration. The destructive influence of the deposit extends to the surrounding textures. One space may be found filled with the diaphanous granular matter, in which traces of a previously existing vessel may be traced in the concentric arrangement of inflammatory nuclei. At the same time effusion of this deposit through an unaltered adventitia, may be demonstrated. The pressure of morbid exudation will necessarily be most evident at the point of least resistance. For these reasons the author believes 'granular degeneration' to be a pure *Lymphorrhagia*—a process by which the pathological results of inflammation may be washed away.

With reference to the present subject, Dr. Benedikt criticises a paper by Dr. Clarke on the pathology of Tetanus (*Med.-Chir. Trans.*, 1865), and considers that the appearances are misunderstood by Dr. Clarke when he describes the structures as broken down and reduced to the state of granular disintegration.

[It may be stated, however, that Benedikt has not seen Dr. Clarke's preparations, showing the changes of the cord. We would take occasion also to observe that, inasmuch as the existence of perivascular lymph-spaces is somewhat more than doubtful, any criticisms or reasoning founded thereon are liable to be proved fallacious.—*Ref.*]

W. B. KESTEVEN.

LETZERICH ON THE EVULSION OF A DIPHTHERITIC TONSIL.—Dr. Ludwig Letzerich writes as follows in no. 28 of the *Berliner Klinische Wochenschrift* (July 13, 1874). At the beginning of June I received from Dr. Rosenkranz, of Usingen, a freshly torn-out tonsil, with the following history. It was from a stoutly built child, three years of age, whom he first saw on May 14 last. It was said to have recovered from epidemic parotitis, but now had a hard swelling at the left angle of the lower jaw. Examination showed a yellowish dirty-looking patch on the left tonsil, which was removed with forceps, and a strong solution of caustic applied. The diphtheritic process was not checked, and two days before its death the child was unable to swallow, and in one of the suffocative attacks tore out with its own fingers two portions, including the tonsil I received, and a part of the velum palati; this was followed by very free hæmorrhage, for which Dr. Rosenkranz was summoned, but the child died before he could reach the house. The death occurred on June 3. The long duration of the illness is noteworthy. The torn out masses were deeply tinged with blood. The larger one (the tonsil) was one inch long, and five-eighths of an inch in diameter; the smaller portion (a piece of tonsil and part of the soft palate) one-third of an inch nearly in diameter, and three-quarters of an inch nearly in length. Both pieces had numerous fringe-like appendages, from one-eighth to three-eighths of an inch in length. On section they appeared

* Beale's *Archives*, no. ix. &c.

composed partly of spongy (crumb-like) tissue, partly of a reticular structure, very irregularly intermingled. The spongy portions could be easily detached, like the scales of an onion, only less regularly arranged, and they were most abundant at the point first attacked, and on the free surface of the tonsil. The smaller piece had a spongy structure throughout. All over the section there were coagula of blood; partly in enormously dilated blood-vessels with thin walls, especially in the veins, and partly extravasated into the tissues of both specimens. Wherever blood had been extravasated, the surrounding tissue was blood-stained for some distance. Microscopic examination showed that the spongy portions consisted of tissue undergoing molecular disintegration (fibrillæ of connective tissue, with round cells), in which sporules of the diphtheria fungus of about $\frac{1}{1000}$ of an inch in size, were found, either singly or in broad black masses, $\frac{1}{833}$ to $\frac{1}{250}$ of an inch in length, and $\frac{1}{1250}$ to $\frac{1}{500}$ of an inch in breadth. [There seems some mistake in these figures, probably due to the decimal point being misplaced.—*Rep.*] Besides these sporules, there were here and there vast masses of the micrococci of the diphtheria fungus. (The author refers to a forthcoming paper of his, 'On the Development of the Diphtheria Fungus' in Virchow's *Archives*). Sections of the smaller specimen gave similar results, except that bundles of elastic tissue were met with in the connective tissue undergoing molecular disintegration, and some of these were quite free from the fungus. Only the portions which appeared sound to the naked eye resembled the normal structure, when examined microscopically. Even in these, for the most part, one missed the beautiful spheroidal cells, usually found in the fine meshes of their connective tissue, and they were often replaced by astonishingly large masses of the micrococci of the diphtheria fungus, whose presence in the meshes of connective tissue had given rise to destruction or disappearance of the cellular elements. On the free surfaces of the tonsils, on both sides, and especially in the patch first attacked, the naked eye perceived destruction of tissue most clearly, and fungi in various stages of development were seen by the microscope. Some of the micrococcus masses were bell-shaped. We have here, therefore, an extremely severe case of mycosis of the tonsils. It was most developed in the deeper tissues (parenchyma) of these organs, and set up molecular degeneration, which allowed the whole of one tonsil to be torn away. In commenting on the case, Dr. Letzerich explains the great differences between the course and severity of different cases of diphtheria, by the fact of the fungus finding a favourable soil or nidus in one case, and not in another. When the soil suits the parasite, the development of its sporules and its aerial fructification is enormously rapid, leading to swift destruction of tissue. When it meets with a less friendly soil, its sporules are converted into fine mycelial threads, and the case may be easily cured, perhaps spontaneously. He has observed that when the oral secretions are very alkaline, the exudation, once removed, is not generally reproduced; hence the mycelium is of subordinate importance in itself, but, should it subsequently find a suitable soil, it may give rise to development of lower forms. The two hyphomycetous forms, one aerial and the other growing in fluids, into which the fungus occasionally sports, have little or no influence on the animal organism. The more the soil is prepared, by means of fermentative

changes induced by the micrococcus-masses on the tonsils, the more rapidly and fully do the parasites develop, and the exudation keeping pace, the tissues become infiltrated and destroyed. [Whether or not we admit that the fungi play so important a part as Dr. Letzerich states, in the history of diphtheria, this case is one of great interest, and his promised paper on the diphtheria fungus will be eagerly welcomed. The reporter has met with several cases of 'muguet' or 'thrush' in the mouth in the course of other diseases, in which the fungoid elements exactly resembled the growths found in pityriasis versicolor, namely, grapelike masses of sporules, with a network of mycelial threads, the so-called 'microsporon furfur.' In cases of diphtheritic exudation he has found repeatedly masses of sporules, etc., and fibrecells resembling the 'oidium albicans.'—*Rep.*]

W. BATHURST WOODMAN, M.D.

BARBOSA ON A SANGUINEOUS CYST OF THE DURA MATER.—At the meeting of the Society of Medical Science, in Lisbon, on May 9 (*O Correio Medico de Lisboa*, June 24), Dr. Barbosa showed a large cyst, situated on the inner surface of the dura mater. It extended over the left cerebral hemisphere, which it depressed considerably. It had a vertical diameter of 18.5 centimètres (about seven and a quarter inches) posteriorly, and of ten centimètres (nearly four inches) anteriorly. Its transverse diameter was 4.5 centimètres behind, and three in front. Its capacity was 350 grammes (about twelve and a half ounces). Except in the region of the tumour, there was no change beyond considerable hyperæmia. The dura mater of the cranium, on being stripped off, did not present any change, and was of the same thickness as that on the right side.

The cyst appeared to be formed between two layers of the dura mater, which were separated by blood. But, on more careful examination, it was found that the outer wall of the cyst was formed of the dura mater, and the inner one of a newly formed very vascular fibrous membrane, almost as thick as the dura mater, and attached externally to the arachnoid. The cavity of the cyst was full of semi-fluid blood, of a chestnut or chocolate colour, with some small dark-yellow clots. Microscopic examination showed that the cyst contained blood-corpuscles altered in form and granular; the colouring matter (hæmatine) forming irregular masses. No crystallised colouring matter or hæmatoidin was found.

The subject from which the specimen was taken was a man aged sixty, of sanguineous temperament and strong constitution, who had been admitted into hospital on March 9, and died thirty-eight days afterwards with symptoms of cerebral compression. The diagnosis before death was congestion of the brain. The patient walked to the hospital and was reported to have been ill about eight days. He was of intemperate habits. His answers to questions were incoherent, and his pulse was slow, sixty in the minute.

Dr. Barbosa attributed the lesion to the abuse of alcoholic drinks, leading to hyperæmia of the meninges and hæmorrhagic pachymeningitis, to which the hæmatoma was due. He agreed with the opinion supported by Calmeil, and Cruveilhier, that hæmorrhagic cysts of the meninges are due to the formation of vascular false membranes within the dura mater, as the result of inflammation of the arachnoid, or of the cranial dura mater. Virchow interprets the formation of these hæmorrhagic

cysts (meningeal or intermeningeal apoplexy), by supposing that the hæmorrhage is preceded by a chronic inflammation of the dura mater, which is frequently seen in mental disease leading to dementia. The inflammation leads to the false membrane, within which successive layers may be deposited by repeated inflammatory attacks in the course of years. These false membranes become very vascular, and their blood-vessels are very thin-walled and fragile, and are consequently easily lacerated and pour out blood.

A. HENRY, M.D.

MEDICINE.

BALFOUR ON THE DIAGNOSIS OF DISEASE OF THE HEART.—In a lecture reprinted from the *Edinburgh Medical Journal* for June, 1874, Dr. George W. Balfour discusses the diagnosis of cardiac disease generally, with special reference to the value of the information derivable from the symptoms and the physical signs. The lecture, while comprehensive, is remarkably concise, and it is consequently by extract rather than by abstract that its principal contents would have to be recorded. After referring briefly to the two most common symptoms of organic disease of the heart—shortness of breath and dropsy, the author describes the systematic physical examination of a patient suffering from such a condition, and discusses the various phenomena which may be elicited. The pulse at the wrist, the venous and the arterial pulse in the neck, the visible and palpable signs presented by the chest and epigastrium, and the results of percussion and auscultation are considered in succession. Under the head of inspection, Dr. Balfour makes the following observations on the diagnosis of adherent pericardium: ‘Depression of the precordial region is much more rare than its elevation, and is the result of previous pericarditis and the indication of the adhesion of the visceral and parietal portions of the pericardium. We must distinguish between a permanent and general depression of the cardiac region and those rhythmical depressions of the intercostal spaces which occur over the apex, or even over a more extended portion of the heart’s surface; which are often the result of adhesions of the pericardium, not only to the heart but also to the pleura and through that to the walls of the chest; but which are sometimes, especially on thin-walled chests, the simple result of atmospheric pressure depressing the intercostal spaces at the moment of cardiac contraction where no adhesions exist: this form of rhythmical depression being invariably associated with some degree of enlargement—not always hypertrophy—of the heart and consequent displacement of the lung.’ And again: ‘In rare instances, a pulsatory movement is also communicated to the epigastrium through the movement of the heart’s apex during the ventricular systole, pulling upwards an adherent pericardium, diaphragm, and liver. This movement is, of course, exactly the reverse of that in ordinary epigastric pulsation. As this extensive adhesion is, as a rule, only the result of a severe and extended inflammation, affecting uniformly the whole surface of the heart, we can readily understand how, in such circumstances, a universal undulatory movement may be perceived, in which when the heart’s action is at all rapid (over ninety beats per minute), it may be

difficult to say what parts of the motion are systolic and what are diastolic. In these circumstances, the variations in time between the movements of any two parts are readily rendered visible, by attaching to each, by means of a pellet of bees-wax, a bristle carrying a small paper flag; and when the pulse is over ninety, this is the only way in which such differences can be ascertained with any certainty; and it is a means of attaining certainty of diagnosis often of much importance, especially when we have pulsations visible above the fourth rib, which may possibly be either aneurisms of the aorta or pulsations of the auricle.’

In percussing the præcordium, Dr. Balfour takes as the vertical line not the left sternal border, but a line one inch to the left of that, which shall be uninfluenced by the aorta and the pulmonary artery.

Referring to accentuation of the second sound at the base of the heart, Dr. Balfour says, that ‘an accentuated pulmonary second is constantly present in every form of cardiac disease involving obstruction to the onward flow of blood, and is the most persistent of all the acoustic phenomena indicative of cardiac disease, being frequently the only thing markedly abnormal to be detected.’ On the other hand, ‘accentuated closure of the aortic semilunar valves, from a general or systemic cause, is not to be thought of; it can only arise from some local cause.’ He does not believe that increase of arterial tension has this effect; and ‘arrives at dilatation of the ascending aorta chiefly, and partly also of the innominate artery, as the sole active causes in producing accentuated closure of the aortic semilunar valves.’ As regards endo-ardiac murmurs, Dr. Balfour insists upon the fact that no murmurs, except the auriculo-systolic, he so-called presystolic murmur, can ever be accepted as a definite sign of actual cardiac disease.

J. MITCHELL BRUCE, M.D.

SIGERSON ON GENERALISED VASO-MOTOR PARALYSIS OF THE UPPER EXTREMITIES.—Dr. Sigerson (*Le Progrès Médical*, April, 1874) remarks that the cases which Dr. Maurice Raynaud has quite recently published on local asphyxia of the extremities present some pathological facts of considerable importance, and which seem to bear on the theoretical explanation which has been drawn from experimental physiology. It is well known that, on dividing the great sympathetic nerve, the vascularity and heat of the corresponding parts of the body are increased, but disappear on galvanising the peripheral end of the nerve. The diminution of heat, however, may be the result of other causes; thus:—1. On dividing the fifth cerebral nerve, hyperæmia of the conjunctiva follows, with falling of the temperature; 2. On tying the veins of the ears of a rabbit the smaller veins dilate, then there is sanguineous stasis, and the ears become cold. In such cases, according to the beautiful experiments of Claude Bernard, a notable augmentation of heat follows section of the sympathetic nerve. It is not so with regard to the lowering of the temperature and the absence of blood which are produced by ligature of arteries.* Now in patients under the observation of M. Raynaud, ‘the extremities,’ he says, ‘become cold, with cyanosis and lividity, and with sensation of a more or less painful kind. Afterwards, in grave cases, gangrenous points make their appearance. The disease is sym-

* Claude Bernard, *Leçons sur la Phys. et la Path. du Système Nerveux*.

metrical, and any accidental symptoms may be intermittent? He thinks that these phenomena must be attributed to derangement of vaso-motor innervation, and that the symmetrical nature of the lesions must depend on excitation arising from spinal centre. He has put forward the hypothesis of spasm of the smallest branches of the vessels, which may vary between simple diminution of calibre and complete closure. With complete closure there would be a bloodless and cadaveric state of the extremities, while with the arterioles alone closed, and the smaller veins open, there would be venous stagnation from want of impulsion, producing cyanosis and the livid aspect, which is seen in the majority of cases. This hypothesis raises some difficulties. It is known, however, that, according to the experiments of Brown-Séquard,* irritation of the vaso-motor nerves produces partial ischæmia, coldness, pallor, and a marked depression of vital activity. But we must not forget that in maladies of this kind, very important lesions have been discovered by M. Charcot (*Leçons sur les Maladies du Système Nerveux*, p. 126), who expresses himself thus: 'As to spontaneous gangrene, which has been attributed to vascular spasm, it would not, if I may judge from my own observations, seem to have the signification which has been given to it, for in all the cases of this kind that I have met with I have found the calibre of the arteries narrowed by the alteration of the arterial walls or blocked up by thrombus.' Similar phenomena of lowered temperature are found in scleroderm, in which we may believe in a diminution of the calibre of the arterioles of the skin in consequence of the morbid process. From the experiments of Waller, who found that ischæmia was soon followed by hyperæmia, in consequence of the withdrawal of nervous influence, we might be tempted to draw a conclusion against the existence of a continuous spasm in non-hysterical patients, if M. O. Weber had not succeeded, as he states, in producing for nearly a week a constant irritation of the cervical sympathetic, marked by a lowering of 2° Centigrade of temperature; but then no disturbance of nutrition supervened. It must be added that Dr. Raynaud cites, in support of his hypothesis, unusual pulsations of the central vein of the retina, and partial spasmodic strangulation of the arteries of that region, which were sometimes met with in the cases of local asphyxia which he has collected.

J. LOCKHART CLARKE, M.D.

CANTILENA ON CALLOUS MEDIASTINO-PERICARDITIS.—Dr. Paolo Cantilena relates (*Giornale Veneto di Scienze Mediche*, July, 1874) a case of pleurisy complicated with 'callous mediastino-pericarditis.'

The patient was a young man, aged twenty-two, a printer, of general good health and somewhat lymphatic temperament, who was admitted into the hospital at Belluno, on the twentieth day of an attack of pleurisy of the left side. The amount of sero-fibrinous liquidation was moderate, the constitutional disturbances slight, and he appeared to be recovering under treatment by diuretics and rest. A substernal pain, however, though slight, directed attention to the heart, which had been thrust to the right of the sternum. At this part there was heard a short murmur with the first sound, more distinct at the apex, as well as another murmur during the

brief pause following by the normal second sound. The intermediate murmur was modified by compression of the chest and by changing the position of the patient, and was diagnosed to the pericardial. The amount of pericardial effusion caused the dulness on percussion to extend some centimètres to the right of the sternum, and as high as the second intercostal spine; on the left, it became blended with the dulness produced by the pleuritic exudation, and below was limited by a curve with the concavity directed downwards.

Under the use of digitalis, quinine, and diuretics, the fever ceased, and the area of cardiac dulness was lessened, the limits of the pleuritic exudation remaining unchanged; the normal heart-sounds were heard, and the pulse acquired strength. The slight œdema of the face and neck, however, which had accompanied the pericarditis, visibly increased, and was attended with a cyanotic tint; the left external jugular vein was distended; the liver was enlarged, reaching below nearly to the umbilicus, and reaching above to the intercostal space near the sternum, to the seventh in the axillary region, and to the tenth rib posteriorly. The spleen was a little enlarged. There was very slight œdema of the lower limbs.

While the pleuritic exudation was absorbed under the use of tonics and resolvents, the heart, though it had returned to the left of the sternum, did not follow the respiratory movements of the diaphragm, but remained fixed at the same height, and, on percussion over a part reaching from the base of the heart as far as the second intercostal space, increased dulness was heard for about two centimètres to the right of the sternum. This led Dr. Cantilena to infer that the œdema and cyanosis of the face and neck, and the enlargement of the liver, depended on the presence of the results of mediastinitis, which impeded the return of blood through the venæ cavae.

This diagnosis was confirmed, Dr. Cantilena believes, by two phenomena which were observed. On making the patient breathe deeply, while the finger was kept on the pulse, the pulsations of the radial artery were observed to become more frequent; when expiration commenced, they ceased altogether; and the pulse then suddenly resumed its normal rhythm. On auscultation at the same time, there was an absence of the first sound over the aorta. The second phenomenon was the distension of the left external jugular vein during inspiration.

At the time of the report the patient was improving in health, under the use of iron, quinine, iodide of potassium, and liberal diet.

[This case should be compared with those described by Kussmaul (*LONDON MEDICAL RECORD*, December 17, 1873); and with Dr. Clifford Allbutt's case of mediastinal sarcoma, reported in the last number of the *British Medical Journal*.]

BERTI ON A CASE OF DEATH FROM ACETONÆMIA, OCCURRING IN A DIABETIC PATIENT.—The *Giornale Veneto di Scienze Mediche* for April contains the history of a case of fatal acetonæmia related to the Royal Venetian Institute of Sciences, by Dr. A. Berti. The patient was a woman aged thirty-one, married, and the mother of four children, in whom symptoms of diabetes mellitus began to appear in June, 1873. She was admitted to hospital on November 27, when the following was her condition.

She was of good physical conformation, but very emaciated and anæmic. In the right subclavian and corresponding supraclavicular regions there

* Course of Lectures, 1860, p. 147.

were diminished elasticity and resonance on percussion, rough inspiration accompanied by subcrepitant rales, prolonged expiration, and increased vocal fremitus and resonance. In the other parts of the chest nothing was heard beyond dry sonorous rales, with some bubbling. Nothing abnormal was discovered on examination of the heart, liver, spleen, and intestines; the teeth were carious, the breath offensive; the urine was copious, having a specific gravity of 1060, and containing sugar in the proportion of fifty grammes per litre. The skin was dry; the patient complained of a disagreeable pasty taste; pains in the gums and teeth, inodorous sour eructations; pain in the epigastrium; great thirst, polyuria, and excessive appetite; she had a dry cough, and was very weak; she was obstinately constipated, and complained of burning and itching during micturition. The pudenda were red and hot, and covered with a dirty viscid discharge. There were no signs of disturbance of general sensibility or mobility. Of the special senses, sight alone appeared to be affected. She had double vision, and at one time she had difficulty in distinguishing darkness from light. The intellect was unaffected.

She remained in nearly the same state during four days. The temperature in the axilla varied from 99.5° to 101.1° Fahr., and the quantity of urine passed in twenty-four hours amounted to four or five litres, the amount of drink taken in the same time being from three-and-a-half to four litres. There was no trace of albumen; the quantity of sugar remained the same as on the first day, the proportion being greatest in the evening.

On the night of the fourth day, the medical officer on duty was called to her on account of a sudden change in her condition. He found her suffering from severe dyspnoea, with dry tongue, flatulence, and pain in the abdomen, and prescribed a calmative mixture and a purgative enema. The next morning, when Dr. Berti saw her, she lay on the bed in a state of profound coma, from which she could not be roused. Now and then she uttered a sharp cry, at the same time carrying the right hand automatically to the head. The eyes were closed, the pupils dilated and almost insensible to the stimulus of light; sensation and motion, as well as reflex action, were almost extinguished; the respiration was frequent, difficult, and hoarse. The discharge of urine was completely suspended; none escaped through the catheter on its introduction early in the morning, but somewhat later about a hundred grammes (between three and four ounces) were removed. This urine contained an abundance of sugar, had no trace of albumen, and under the microscope showed only a few epithelial cells and some blood-corpuscles. The patient also exhaled an odour as of chloroform.

From a consideration of the patient's history and symptoms, Dr. Berti concluded that he had to deal with a severe form of acetonæmia. He therefore applied a blister to the nape of the neck, painted over the lower limbs with a mixture of mustard and alcohol, and ordered a purgative enema and stimulants internally. The patient remained in the same state about twenty-four hours, and then died. The odour already described became more intense, and at last escaped from the open mouth of the corpse.

The symptoms in this case, Dr. Berti says, bore a close resemblance to those described by Cantani in speaking of acetonæmia.

'In the fourth type of acetonæmia' (says Cantani),

'the patient falls unconscious, and presents all the appearance of being under the influence of chloroform. There is generally a very strong smell of acetone in his breath and urine; the muscular debility is enormous; the pupils do not act; when the arms are raised, they fall again like those of a dead man; the abdomen is in a state of meteorism, through paralysis of the intestines; the renal secretion is suppressed, the mucous membranes become dry; the skin is not acted on by revulsives, or only slightly; the pulse becomes small and weak; and finally death ensues.' We might say that in such cases there is truly a general paralysis of the animal and organic system, due to the narcotising action of acetone produced in excess in the system.

At the necropsy, the sinuses of the dura mater were found to be gorged with blood; there was venous congestion of the meninges; the subarachnoid space and cerebral ventricles contained serum; the substance of the brain was somewhat softened. There was no apparent change in or near the fourth ventricle. The lungs were congested and oedematous; the apex of the right was scarcely permeable to air. The heart was small and contracted; its walls and valves were healthy; the liver was rather hard, and much congested; the spleen was normal; the kidneys were anæmic, but presented no change of structure; the bladder had several spots of ecchymosis of various size in its interior. There was nothing remarkable in the other organs. An odour of acetone escaped from all the cavities of the body, including the head.

Dr. Berti sent to Professor Bizio, for examination, some of the blood from the left ventricle of the heart, pieces of the brain and liver, and one of the kidneys. Distinct evidence of acetone was found in all on the application of chemical tests. Sugar was also found in the blood and in the viscera, the smallest amount being in the brain.

A. HENRY, M.D.

SURGERY.

BOINET ON GASTROTOMY.—M. Boinet says (*Gazette Médicale de Paris*, April 25, 1874), gastrotomy has been and may or ought to be practised in certain lesions of the digestive organs. He quotes seven cases of accidental wounds of the stomach (from various sources) all ending in cure, and argues that a scientific operation should give at least equal chances.

In Cases 1 and 2 the wounds appear to have been small, but large enough to allow the escape of beer in the one case and food in the other from the external opening. The first, treated by rest and the internal administration of alum, was well in seventeen days. The second was treated by three bleedings, and passed through a sharp attack of traumatic fever, with disturbance about the wound, but was quite well in seven weeks.

Cases 3, 4, and 5, were similar, but the wounds appear to have been larger and were treated by suture. [By what kind of suture, and how used, is not clear.—*Rep.*] All recovered perfectly. In Case 6 the stomach and part of the omentum formed a hernia which could not be reduced, as each attempt caused a curious suffocative paroxysm: later, an attempt to cure by suture failed, the stitches tearing out. Nature cured the fistula, however, in two months.

Case 7 is the well-known one of the Canadian who

was wounded by gunshot, and in whom a fistulous opening remained, by means of which Beaumont experimented on digestion.

From these cases M. Boinet argues :

1. That openings made into the stomach do not necessarily cause death ;
2. That they may be cured by suture ;
3. That the great danger lies in the escape of aliments or blood into the peritoneum.

Hence gastrotomy for certain wounds and diseases of the stomach and intestines is a justifiable operation, provided great care to prevent escape of matters into the peritoneum be taken, or if any do escape they must be thoroughly cleansed out. He quotes the success of ovariectomy in support of his view.

[M. Boinet hardly makes here a fair comparison ; the matters from stomach and intestine, full of ferments or germs of putrefaction, can hardly be compared with ovarian fluid, which, we know, may escape without harm. How is it in accidental perforation of the intestines ?—*Rep.*]

J. KNOWSLEY THORNTON.

VANDERVEER ON STRICTURE OF THE URETHRA. Dr. A. Vanderveer, of Albany, in a report (*American Journal of Medical Science*, July, 1874), of twenty cases of stricture of the male urethra with treatment, makes the following remarks :

From the foregoing cases, we are led to believe that the treatment of stricture by gradual dilatation when possible, is by far the simplest and safest method. To insure success, the gradual dilatation must be kept up for years at intervals. In strictures of small calibre, where it is only possible to introduce the whalebone guide, divulsion in the membranous portion, and internal urethrotomy in the spongy portion, are the better methods. Strictures in the spongy portion, in consequence of their painful character, do not well bear treatment by gradual dilatation, particularly if the case be one of long standing.

The twenty cases reported include eighteen of gonorrheal origin and two of traumatic origin. Eleven were cases of single stricture, six presented two strictures for treatment, one case offered three strictures, another five, and another six for treatment. Seven cases were submitted to the treatment by gradual dilatation, three to gradual dilatation combined with divulsion, two to gradual dilatation with meatotomy, one to gradual dilatation with urethrotomy, one to a combination of gradual dilatation, meatotomy, and urethrotomy, three were treated by divulsion only, two by divulsion and meatotomy, and one by meatotomy and urethrotomy. The shortest time any patient remained under the surgeon's treatment was one week. The treatment of one case occupied eight months. All the patients recovered.

Comparing the methods of treatment with regard to their duration, it may be observed that the three cases submitted to divulsion were dismissed, two at the end of a week each, and one in fifteen days. Of those patients treated by gradual dilatation, two were dismissed at the end of two months, one at the end of four months, one at the end of five months, two after six months' treatment, and one at the expiration of eight months.

[Gradual dilatation may be the simplest and safest method of treatment in Dr. Vanderveer's estimation, but it is, according to his own cases, by no means the speediest method.—*Rep.*] J. CROFT.

OBSTETRICS AND GYNÆCOLOGY.

BÉHIER ON TRANSFUSION IN EXTREME ANÆMIA.—M. Béhier relates this case in the *Bulletin Général de Thérapeutique*, March 15 and 30, 1874. The operation was performed on a young woman aged twenty-one, who had been confined of a male child sixteen months previously, which she nursed up to the time of entering the Hôtel Dieu. The catamenia came on when she was thirteen years, and continued regular until she became pregnant. They returned eleven months after the birth of the child, being regular as to time, but excessive in quantity. They were fifteen days behind time when she was suddenly seized, on January 12, with severe flooding, which continued until the 14th, when she was brought into the hospital in a most exhausted condition from excessive loss of blood. On examination, the vagina was found filled with clots ; the cervix was short, large, and firm, and the os half open. No tumour could be felt, nor did digital examination give rise to any pain. Ice was applied to the abdomen, and steel given internally, and the vagina plugged. This arrested the flow for a time ; but it recurred on the removal of the plug. The woman being in extreme danger, it was decided to transfuse as the last chance.

The instrument used was the Moncoq-Mathieu hæmatophore, which admits of transfusion without first of all defibrinating the blood, and is a combination of the two instruments of M. Moncoq and M. Mathieu. In operating, the vein of the patient is opened by a lancet, as in phlebotomy, care being taken not to divide the vessel, and the cannula was introduced. A similar operation is performed on the person from whom the blood was taken. The instrument is previously warmed to a temperature of 39°-40° C. (102° to 104° Fahr.) with pure warm water. The blood should be forced in very slowly, and in a continuous stream ; if this precaution be neglected, death is liable to occur from syncope or convulsions, accompanied with vomiting, as has been shown by Dr. Brown-Séquard. The syncope is most probably the result of paralysis of the right ventricle of the heart from over-distension. There are other accidents liable to happen, the explanation of which is not easy. For instance, if the blood be introduced too abruptly, or in too great quantity at a time, the patient will be observed to fall suddenly into a kind of inertia ; at the same time the face swells and becomes pale, the eyelids puffed, assuming a slightly violet tint ; there is almost complete torpor, and the patient dies, not suddenly, but after some hours. Whether this be the result of asphyxia consequent on engorgement of the lungs through too much blood being injected at a time, or whether from cerebral asphyxia through too rapid distension of vessels of the brain consequent on the arrest of the pulmonary circulation, or whether it be the effect of paralysis of the right ventricle, it is not clear. Another symptom of much importance, is a short dry cough. As soon as it occurs, the transfusion should be stopped, for it is the first indication of pulmonary congestion. Care should be taken not to inject too much blood at one time. If there be any necessity for injecting more blood, it is far better to repeat the operation.

In the present instance, eighty grammes of blood were transfused on January 29. Immediately after the operation, the patient presented a wan look ; at

times the face was puffed. The respirations were laboured and deep; she tossed about, was slightly delirious and anxious, and said that she felt dying. The excitement increased, coupled with dyspnoea and mournful cries. An hour and five minutes after the operation the voice was stronger, and she complained that her feet were swelling. She evidently displayed more force than before. Five minutes later she was able to raise her head without difficulty, and take a little wine, which was retained; the pulse was imperceptible at the radials. Ten minutes later she was still in continual agitation; she thought her abdomen was swelling as well as her feet. The respirations were rapid, gasping as in asphyxia. Her face was haggard, and slightly cyanotic. This condition continued for about an hour and a half (until three hours after the operation), when a change for the better took place. The hands became warm, the pulse stronger; the patient said that she felt better. At the end of two hours and a half (four hours after the transfusion) the haggard appearance of the countenance entirely disappeared; the face showed signs of returning colour; there was no delirium nor agitation. Six hours after the operation, she had been able to take, without vomiting, a basin of soup and nearly a bottle of wine. The pulse was full. She could listen without fatigue, and distinguished colours. The headache had entirely disappeared. The bleeding entirely ceased from the moment of the operation. She made rapid improvement during the next two days. On the evening of the third day (January 31) there was a rapid rise in the temperature of 3°C ., but she felt well and asked for more food. M. Béhier considered that there was probably a 'fièvre d'alimentation,' as it soon subsided. On February 4 she was out of danger, and could eat, drink, etc., as usual. Up to the date of the report (two months after the operation) convalescence continued without a relapse.

M. Béhier is strongly in favour of using the normal blood, not defibrinated; for, although the fibrine of the blood has been regarded by many physiologists as an excrementitious product—a waste material destined to be eliminated—still the experiments of Magendie have conclusively proved that the fibrine is not without its use, and that blood deprived of it gives rise to engorgement and visceral hæmorrhages. Still more recently M. Cl. Bernard has arrived at almost the same conclusion, and, according to him, if the fibrine have an use still little known, it is certainly no inconsiderable one, for, without doubt, it keeps the corpuscles suspended in the blood. M. Béhier entirely agrees with Gesellius of St. Petersburg, that the red corpuscles are deformed and crenated—in fact, 'battus à mort'—by the process of defibrination. The following statistics are given as conclusively proving the superiority of the transfusion of the normal blood, over the defibrinated.

M. de Belina collected 155 cases, which were nearly all the known cases up to 1869. In 1871, Asche (Schmidt's *Jahresbericht*) collected seventy-five fresh cases, making in all 230. Unfortunately, the results were given without stating what the conditions were or what kind of blood was used. M. Marmonier, however, collected thirty-four observations in which defibrinated blood was used. There were twenty-two deaths—a mortality of two in three. In 113 cases natural blood was employed; thirty-four died, *i.e.* one in three only. Professor Hüter (Greifswald) performed arterial transfusion in twenty

cases; some died, others survived. The advantages are not worth the increased risk.

Finally, the blood of mammalia have been injected; the experiments of M. Denis and Lower proved that from 400 to 600 grammes of sheeps' or calves' blood could be injected with impunity into a man; but the investigations of M. Dumas, Prévost, Dieffenbach and Bischoff, tend to show that the admixture of heterogenous blood is frequently rapidly fatal. M. Landois (*Centralblatt*, 1873, nos. 56, and 57) found that the serum of the blood of an animal dissolved more or less rapidly the red corpuscles of the blood of another animal. The solvent power of the serum was different in different animals, the least in dog's blood.

The effect, therefore, of transfusing the blood of an animal would be very transient in its effect, as the hæmatine would be slowly dissolved and eliminated by the bowels and the kidneys.

The author, in conclusion, regards transfusion as a reasonable, vigorous, bold and efficacious therapeutic remedy, and as such, recommends it with confidence to the profession.

PAJOT ON THE CAUSES OF ERROR IN THE DIAGNOSIS OF PREGNANCY.—In a previous paper, Dr. Pajot discussed the more ordinary and well-known conditions which render the recognition of pregnancy at times difficult. In this paper (*Bulletin de l'Académie de Médecine* for June) he proceeds to treat of the more exceptional instances, and mentions a symptom, which he designates 'choc fœtal,' or fœtal impulse, discoverable between the fourth and fifth month of gestation, as highly diagnostic, and, when once heard, as certain a sign as the sounds of the fœtal heart. The *modus operandi* he gives with great precision.

The writer instances *extreme thinness of the uterine walls* as an occasion for error. It is a rare condition, and, when met with, the enlarged uterus is not unfrequently mistaken for a cystic tumour. The extent to which this can go is marvellous, the fœtus appearing to be just beneath the skin. *The death of the fœtus* within the first few months renders diagnosis extremely difficult and obscure. The chief thing is to decide whether the tumour is the uterus or not. This is best effected by placing the proned left hand on the abdomen, so as to grasp the fundus with the tips of the fingers, and with the right index finger to push up the cervix. Any impulse given is immediately perceptible. Then the order is reversed, keeping the right hand fixed and making movement with the left. Velpeau maintained that by this means the uterus could be as easily measured as if it were on the table.

It should always be remembered that the body of the normal non-pregnant uterus cannot be felt in any of the culs-de-sac when digital examination is only lightly made, so as to put the pouches gently on the stretch. This arises from the junction of the body and the cervix being the narrowest part of the uterus. If the body be easily felt, it is either a pathological or a physiological condition, and requires the greatest care and nicety to decide which it is. Pregnancy being diagnosed, M. Pajot strongly urges that the waters should not be ruptured or labour hastened when the fœtus is dead, as septic poisoning is very liable to occur from rapid decomposition of the macerated fœtus. As long as the membranes are intact, maceration may go on with impunity.

[Various authors have published undoubted cases

of septic poisoning of the mother from decomposition of the foetus, although the waters had not ruptured. Dr. Fordyce Barker, in his work on *Puerperal Diseases*, relates two instances as occurring in his practice.—*Rep.*

'Choc foetal' is evidently a movement of the foetus, but of its exact nature the author is ignorant. It is only discoverable by aid of the stethoscope, and, when once heard, although a very delicate sign, it is a sure indication of pregnancy. The following precautions are necessary to catch this movement, which strikes the ear to be a double sensation, a cross between a jerk (choc) and a 'bruit brusque,' but of extreme lightness (*légereté*), giving the impression that it is of a semi-tactile and semi-auditory nature. It is entirely distinct from all other sounds or sensations perceptible in the abdomen. The stethoscope has to be placed perpendicularly on the most prominent part of the tumour, and carefully poised until the ear is brought to bear on it, care being taken that the foot-piece lies flat on the abdominal walls. Pressure is now gently made with the head, so as to press the abdominal walls slightly against the uterine, but no further. At times one has to grope about to catch it, as with a specimen under the microscope. To educate the ear, it is better to study it between the fifth and sixth month of gestation, as the sensation is much more perceptible, but duller, 'brusque soubresaut.' Whenever there is doubt respecting a pregnancy, a decided answer should never be given, as in all obscure cases time is the best means of diagnosis.

AWATER AND MARTIN ON HYSTEROTOMY.—At the meeting of the Gynæcological Society of Berlin, on March 17 (*Berliner Klinische Wochenschrift*), Herr Awater read a paper, in which he advocated the bloody (*blutige*) dilatation of the cervical canal in preference to the use of sponge-tents, on account of (1) the difficulty in introducing them in extremely anteverted uteri; (2) the uncertainty of the times during which they should be left in; (3) the ease with which inflammations may be sometimes set up.

Dr. E. Martin stated during the discussion that ensued, that he had performed hysterotomy in 300 cases. The incision rapidly healed if the wound were not kept open by sponge-tents, which he invariably did. If there were much hæmorrhage, a plug of cotton-wool, dipped in liquor ferri, was introduced. He, as a rule, kept the sponge-tents twenty-four hours in the canal. An offensive odour arose most frequently, and was of a very intense character, when there was antecedent endometritis or chronic colpitis. He had never seen infection occur after their use that he could fairly assign to the tents. Parametritis was certainly to be attributed to the constitutional diathesis of the patient. In pregnant women the application of the tents was attended with much danger; perhaps it was on account of the larger size of the vessels. Certain cautions should never be neglected, such as disinfecting injections; and tents with smooth surfaces should always be chosen, as they did not expand so rapidly, and also abraded the parts less on their introduction. The effects of the laminaria tents were more transient, produced the same offensive discharges, and one fatal case of parametritis and perimetritis had occurred through their use. The general feeling of the society was that they were not particularly dangerous.

MILNE ON OCCASIONAL ARRESTING AND DISCUTIENT INFLUENCE OF PREGNANCY OVER PELVIC ABDOMINAL TUMOURS.—Dr. Alexander Milne read a paper on the subject before the Obstetrical Society of Edinburgh, on May 13, 1874, illustrating it by three cases (*Edinburgh Medical Journal*, August, 1874). He combats the view that has been held by most authorities, that pregnancy is favourable to the growth of cysts, exciting inflammation, or causing adhesions, or leading to suppuration, and that women with cystic ovaries should either not marry, or, if married, should refrain from intercourse. He relates three cases, showing that it had the most beneficial effect in causing complete absorption of the ovarian cyst.

Case 1.—A single lady consulted him previously to marriage, in whom he discovered in the right utero-rectal fossa an unilocular ovarian cyst, about the size of an orange. About the end of the fourth month of pregnancy, she was seized with sharp pains over the abdomen, and was exceedingly prostrate when seen, rejecting all food. Pain was relieved by opium, and the vomiting ceased in a couple of days. She was delivered at full time with a healthy child; and has had two children since. The tumour quite disappeared. [It is not stated when the cyst disappeared, whether before or after her first confinement or one of the subsequent labours.—*Rep.*]

Case 2.—A married woman, mother of three children. When in labour with her fourth child, there was found to be a large elastic tumour in Douglas's pouch; it was pushed above the brim, and the delivery was rapidly and safely accomplished. A couple of years afterwards she was again brought to bed; this time the tumour came down as before, but was much smaller. This year she gave birth to a child; the cyst was to be felt, but so much diminished in size that it required no interference.

Case 3.—This case was somewhat similar to the last. The patient was a multipara. The tumour could not be returned, and had to be delivered by turning twelve hours after parturition. There were intense abdominal pain and other symptoms of peritonitis. The woman recovered. Dr. Milne had not seen her since, to make any examination as to whether the tumour had diminished or not, but he believed such to have been the case.

These tumours were all diagnosed as unilocular ovarian cysts, and were discussed, the writer believes, through the pressure of the gravid uterus, acting similarly to the effect produced by external bandaging. Instead of matrimony or intercourse being prohibited, it should be regarded as a remedial measure.

W. C. GRIGG, M.D.

SUCCESSFUL REMOVAL OF UTERUS AND BOTH OVARIES.—The *American Journal of Medical Science* for July quotes from a report from Sumter County, in the *Transactions of the Alabama Medical Association*, a case of the removal, for fibroid disease, of the entire uterus and both ovaries. In removing this mass, weighing over six pounds, the whole of the small intestine was lifted out of the abdomen to gain room. Five silk ligatures were applied to the arteries, cut close, and allowed to remain. The cavity and bowels being carefully sponged with tepid water, the incisions were closed with silver sutures, covered closely and tightly with bands of adhesive plaster. The operation was attended with severe shock, and followed by violent vomiting. During a paroxysm of retching a knuckle of intestine protruded

through the wound, and was slightly torn by a wire suture. The edges of the rent were fastened to the edges of the wound in the abdomen. Symptoms of pyæmia repeatedly occurred. On the tenth day clots and pus were discharged through an incision in the posterior vaginal wall. The incisions in the abdomen, except at the fistula, healed by first intention. The sutures were removed on the tenth day, but supporting plasters were longer used. This patient fully recovered. Attempts made to close the fistula reduced it to dimensions not practically troublesome. Three years afterwards the patient, a negress of thirty or forty years of age, was in perfect health, working daily. The reporters attributed the removal of the alarming symptoms of septic poisoning to calomel in purgative doses, although using beef-essence and stimulants.

SIMMONS ON THE ADMINISTRATION OF HYDRATE OF CHLORAL BY THE RECTUM IN THE VOMITING OF PREGNANCY.—Dr. D. B. Simmons, chief surgeon to Ken Hospital, Yokohama, Japan, reports (*New York Medical Record*, June 1, 1874) four cases of excessive vomiting of pregnancy, in which thirty-grain doses of chloral, morning and evening, administered in mucilage by the rectum, afforded marked relief. Should another opportunity offer, writes Dr. Simmons, for a trial of this plan of treatment, we have decided to commence with larger doses, being convinced that a decided impression, produced by the medicine at first, will require its repetition but two or three times to put an end to the disease, for the time at least. We believe that hydrate of chloral, administered in this manner, will relieve most cases of nervous or sympathetic vomiting, where there is no inflammation especially. Even in strangulated hernia, on theoretical grounds, it ought to act well, not only in checking the vomiting, but in producing relaxation. We should give it a trial also in cholera.

MISCELLANY.

DR. LUDWIG has been nominated Professor of Physiological and Pathological Chemistry in the University of Vienna.

A NEW PROVINCIAL COLLEGE.—We understand that arrangements are in progress for the establishment in Bristol of a College of Science and Literature, of which the Medical School, which has existed in that city for many years, shall form a department.

FEMALE ARMY-SURGEONS.—The Vienna *Medicinisch-Chirurgische Centralblatt* reports that the Committee of the Society for the care of the Sick and Wounded in War in St. Petersburg, has approved of a proposal for allowing women to perform the duties of military surgeons in the field and in stationary hospitals. To carry out the plan it is intended to institute courses of instruction for female army-surgeons (*Feldscheererinnen*) in the Russian universities.

THE FAMILY BONAPARTE.—Madame Letitia Rat-tazzi, one of the members of the family Bonaparte, has for some months been visiting the principal towns of Europe, to study the ways and means of establishing a hospital which shall be especially devoted to the treatment of cancer. As is well-known, several of the members of this family have succumbed to this terrible disease. The first deposit will be 150,000 francs, to which will be added a biennial prize of 5,000 francs for the best work on the subject, as well as a sum of 20,000 francs for him who shall describe the true cure for cancer.

RELICS OF THE PAST.—We learn from Brünn, the capital of Moravia, that some enormous skeletons of gigantic animals, presumably mammoths, have been found at a place called Bohonitz, in the environs of the city. The class to which the animals belong is determined by the discovery of a tooth of the mammoth similar to one found in the same neighbourhood in 1795, and preserved in the museum of Brünn.

AMBULANT HOSPITALS.—The continental press is much occupied at present with the utility and necessity of organising ambulant hospitals, like that which is proposed by the local directors of the Society for aid to the sick and wounded of the Government of Linibirsk. In a province in the south of Russia, a medical man is engaged for a modest sum furnished by the local directors of the society, to visit the villages in time of peace, to attend the sick gratis, and to send them to the nearest hospital if their disease requires long and special treatment. In time of war ambulant hospitals of the same kind could act in the rear of the active army, and it is to be supposed that if they were organised on a practical basis they would prove very useful to wounded or sick soldiers.

‘NOTHING NEW UNDER THE SUN.’—Doctor Mordtmann, of Constantinople, publishes in the *Gazette Médicale de l’Orient* some curious details he has discovered in some old Oriental chronicles, tending to show that the Siamese Twins, as well as the Sisters Milly and Christine, had prototypes in former times. According to these Byzantine chronicles, there came from Armenia to Constantinople in the year 744, a monster, consisting of two children born of one mother. These children were attached to one another at the epigastrium, so that they faced each other, the other parts of their bodies being regularly formed. During their sojourn in the Byzantine capital numbers flocked to see this monstrosity; but as the twins were superstitiously regarded by the ecclesiastical authorities as being of bad augury, they were expelled the city, to return again when a comparatively enlightened emperor ascended the throne of the Cæsars. One of these twins died, and the most skilful physicians endeavoured to divide the survivor from the corpse at the point of juncture, in the hope of saving his life. The operation, however, only served to prolong its duration for three days.

NOTICE.

THE LONDON MEDICAL RECORD is published every Wednesday morning, and may be ordered direct from the Publishers, Annual Subscription, 17s. 4d.; free by post, 19s. 6d.

Reading Covers to hold 12 numbers of THE LONDON MEDICAL RECORD have been prepared, and may be had direct from the Publishers or through any Bookseller, price 2s. 6d. each.

Foreign Books for review in this Journal may be sent addressed to the EDITOR, care of Messrs. DULAU & Co., London; and through their Agents:—Paris: Mr. G. BOS-SANGE, Rue Quatre-Septembre—Leipzig: Mr. K. F. KOEHLER—Florence: Mr. E. LOESCHER—Brussels: Mr. C. MUQUARDT.

The First Volume, containing upwards of Two Thousand Articles abstracted and compiled by a staff of Fifty Hospital Surgeons and Physicians, is now ready, price 19s. 6d. Cloth Cases for binding the Numbers for the year 1873 are also ready, price 1s. 6d. each.

Home and Foreign Agents for THE LONDON MEDICAL RECORD:—Edinburgh: MACLACHLAN & STEWART—Amsterdam: W. H. KIRBERGER—Bombay: THACKER, VINING & Co.—Calcutta: THACKER, SPINK & Co.—Melbourne: GEORGE ROBERTSON—Montreal: W. DAWSON & Co.—New York: G. PUTNAM'S SONS—Paris: JOHN ARTHUR & Co., 10 Rue Castiglione.

Advertisements should be sent to the Office, 15 Waterloo Place, S. W., before Twelve o'clock on Tuesday morning.

The London Medical Record.

EDUCATIONAL NUMBER.

WEDNESDAY, SEPTEMBER 16, 1874.

Authors of Papers, Theses, &c., will assist in the preparation of summaries by our reporters, by forwarding separate copies of their works.

HOSPITAL STUDY.

Some of the Metropolitan medical schools give in their prospectuses advice to the students, as to the course which they should follow in attending lectures, and especially hospital practice. The order of attendance on lectures will, of course, be regulated according to the subjects on which the student has to be examined by the licensing boards; but the following suggestions as to the course of practical study, taken from the Guy's Hospital prospectus, will, we think, be an useful guide as to hospital work.

At the end of the first year, or early in the second winter session, the appointment of assistant-surgeon's clerk may be held with advantage, and the application of anatomy to surgery should be studied among the surgical out-patients.

As soon as the primary examination is passed, the duties of surgical ward clerk should be entered on, and the wards, *post mortem* room, and out-patient rooms constantly frequented.

The next appointment should be that of medical ward clerk; and at this time the elements of physical diagnosis should be learnt, every effort being made to train the eye, the hand, and the ear, as well as to learn how to use the various instruments of investigation. The knowledge before acquired of microscopical and of chemical manipulation will now be fully applied; and the subject of morbid anatomy should be studied as each case arises.

The appointment of clerk in the out-patients' room should follow. Cases of midwifery should be attended while following the lectures on that subject.

When these appointments have been held, those of assistant-surgeon's dresser and dresser in the surgery necessarily precede the higher appointments. Those of *post mortem* clerk, dental surgeon's dresser, etc., may also be held advantageously during the third year.

Every student who desires to obtain the greatest advantage from his position as a Guy's man should seek to hold at least one, and, if possible, each in succession, of the higher students' appointments, viz. those of clinical assistant, full dresser, and obstetric resident clerk.

Those gentlemen who intend to take a degree in the University of London must somewhat deviate from the above course. They should defer entering the hospital until they have matriculated. The first

year should be devoted to learning the rudiments of human anatomy, and attending the courses of chemistry, natural philosophy, comparative anatomy and botany, in preparation for the preliminary scientific examination. Special classes in each of these subjects are held and examination papers given.

After this examination has been passed, the second year should be devoted to anatomy, physiology, and the other subjects of the first M.B. examination, and only after passing this should the undergraduate take clinical appointments and enter on practical work in the wards.

REGULATIONS OF THE LICENSING BODIES.

Subjoined are abstracts of the regulations issued by the licensing bodies in England and Scotland. The limited amount of space at our disposal obliges us to give only those portions which are of special interest to present students. In several instances, special exemptions from portions of the examinations are made in the case of candidates who possess the diplomas or degrees, or who have part of the professional examinations, of other examining boards. We have arranged in a tabular form the regulations of the Colleges of Physicians and Surgeons in London, and of the Society of Apothecaries, presenting thereby a synopsis which, we believe, will be interesting and useful to a large proportion of students. In all cases, a preliminary examination in subjects of general education must be passed before the commencement of professional study.

UNIVERSITY OF OXFORD. MEDICINE.

The Degrees of Doctor and Bachelor of Medicine are granted by this University.

BACHELOR OF MEDICINE.—A student deciding to graduate in medicine must, after passing all the requisite examinations for the degree of B.A., spend two years in study prior to a scientific examination for the degree of Bachelor of Medicine, unless he shall have taken a first or second class in the natural science school, when he may go in at the first opportunity for the first M.B. examination. Two years after passing this examination, and after four years of professional and scientific study, he may go in for the second or practical examination for the M.B. degree. These four years of medical study may be spent either in or out of Oxford, in an approved medical school.

DOCTOR OF MEDICINE.—For the Degree of Doctor in Medicine, a dissertation has to be publicly read three years after taking the M.B. degree.

The medical examinations take place annually in Michaelmas Term.

Further information may be obtained from the Registrar of the University, or from the *Student's Handbook of Oxford*.

UNIVERSITY OF CAMBRIDGE.

This University confers the degrees of Bachelor of Medicine, Doctor of Medicine, and Master of Surgery.

BACHELOR OF MEDICINE.—A student proceeding to this degree must—(1) Reside in the University two-thirds of each of nine terms; (2) Pass the Previous Examination, which may be done in the first

or second terms of residence; (3) Pursue medical study for five years, unless he have obtained honours in the Mathematical, Classical, Moral Sciences, or Natural Sciences Tripos, in which case only four years are required. Of this time, he must spend six terms in medical study in the University after passing the Previous Examination; or if he have obtained honours in one of the above-mentioned Triposes, four terms. There are three examinations for the degree of Bachelor of Medicine; the examinations include chemical analysis, practical histology, the recognition and description of specimens (healthy, morbid, and microscopical), dissections, and the examination of patients. The subjects of the first examination are—(1) Mechanics and Hydrostatics; (2) Chemistry with Heat and Electricity; (3) Botany. (Students who have already passed with credit the examinations on these subjects on the Triposes, or for the B.A. degree, are not required to be again examined on them.) The student may present himself for this examination at any time after passing the Previous Examination. He must have attended one course of lectures on Chemistry, including manipulation, and one course on Botany. The subjects of the second examination are—(1) Elements of Comparative Anatomy (except for students who have passed with credit the examination in this subject in the Natural Science Tripos, and have obtained honours); (2) Human Anatomy and Physiology; (3) Pharmacology. The student must have completed two years of medical study, including the time of medical study required to be spent in the University. He must have attended hospital practice during one year, have dissected during one season, and have attended a course of lectures on each of the following subjects: (1) Elements of Comparative Anatomy; (2) Human Anatomy and Physiology; (3) Materia Medica and Pharmacy; (4) Pathology. The subjects of the third examination are—(1) Pathology and the Practice of Physic; (2) Clinical Medicine; (3) Medical Jurisprudence. The student must have completed the course of medical study, must have attended hospital practice during three years, and must have attended one course of lectures on each of the following subjects:—(1) Principles and Practice of Physic; (2) Clinical Medicine; (3) Clinical Surgery; (4) Medical Jurisprudence; (5) Midwifery. He must also have been clinical clerk for six months at least at a recognised hospital; or have, after attendance on hospital practice, attended to practical medicine in the special care of patients in a hospital, dispensary, or parochial union, under superintendence of a qualified practitioner, unless he himself be duly qualified. After these examinations have been passed, the candidate reads a thesis, composed in English by himself on some subject approved by the professor; the professor brings forward arguments or objections in English for the candidate to answer, and examines him *viva voce*.

DOCTOR OF MEDICINE.—This degree may be taken by a Bachelor of Medicine in the ninth term after inauguration. He must have been engaged five years in medical study, keep an Act similar to that for M.B., and write an extempore essay. A Master of Arts may proceed to the degree of M.D. in the twelfth term after his inauguration as M.A., without having taken the degree of M.B. He must pass the three examinations for M.B., and keep the Act for the M.D. degree.

MASTER OF SURGERY.—The subjects of the ex-

amination for this degree are—(1) Surgical Anatomy; (2) Pathology and the Principles and Practice of Surgery; (3) Clinical Surgery; (4) Midwifery. The candidate must have passed all the examinations for the degree of M.B., and must have attended the surgical practice of a hospital for three years; must have been house-surgeon or dresser for six months; and must have attended (1) a second course of lectures on Human Anatomy; (2) one course of lectures on the Principles and Practice of Surgery; (3) lectures on Clinical Surgery during one year; (4) ten cases of Midwifery; and (5) have dissected. The candidate must perform operations on the dead body, and examine patients in the hospital.

UNIVERSITY OF LONDON.

Degrees in Medicine and Surgery.

The following Degrees are granted by the University of London:—Bachelor of Medicine; Doctor of Medicine; Bachelor of Surgery; and Master of Surgery. The certificates in all cases must be transmitted to the registrar at least fourteen days before the commencement of the examination. The fee for each examination is five pounds. If a candidate withdraw or fail to pass either of the examinations, the fee is not returned; but he is admitted without further payment to *two* subsequent preliminary scientific, first M.B., second M.B., or B.S. examinations, or to *one* subsequent M.S. or M.D. examination.

BACHELOR OF MEDICINE.—A candidate for the degree of Bachelor of Medicine must—(1) Have passed the Matriculation Examination, or have taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras (provided that Latin has been one of the subjects). (2) Have passed the Preliminary Scientific Examination (in Mechanics and Natural Philosophy, Inorganic Chemistry, Botany and Vegetable Physiology, and Zoology). (3) Have been engaged in professional studies, during four years subsequently to matriculation or graduation in Arts; one year, at least, of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. Two examinations are required.

First M.B. Examination.—The candidate must have passed the Preliminary Scientific Examination at least one year previously, and must—(1) Have completed his nineteenth year; (2) Have been a student during two years at one or more of the recognised medical institutions or schools; and have attended lectures on each of the three following subjects: Descriptive and Surgical Anatomy; General Anatomy and Physiology; Comparative Anatomy; Pathological Anatomy; Materia Medica and Pharmacy; General Pathology; General Therapeutics; Forensic Medicine; Hygiene; Obstetric Medicine and Diseases peculiar to Women and Infants; Surgery; Medicine; (3) Have dissected during two winter sessions; (4) Have attended a course of Practical Chemistry; (5) Have attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. Candidates are examined in Anatomy; Physiology; * Materia Medica, and Pharmaceutical Chemistry;

* Candidates may postpone the examination in Physiology until the first M.B. examination in the next or any subsequent year; but they cannot compete for honours on either occasion.

Organic Chemistry. Candidate, placed in the first division, may be examined for honours in (1) Anatomy, (2) Physiology, Histology, and Comparative Anatomy, and (3) Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry. If sufficient merit be evinced, the candidate who distinguishes himself most in each of these divisions receives an exhibition of 40*l.* per annum for two years; and the first and second candidates in each subject receive each a gold medal of the value of 5*l.*

Second M.B. Examination.—No candidate is admitted to this examination within two academical years after passing the first examination. He must have subsequently attended a course of lectures on each of the two subjects for which he had not presented certificates at the first examination; have conducted at least twenty labours; have attended the Surgical and the Medical Practice of a recognised hospital or hospitals during two years, with Clinical Instruction and Lectures, and have subsequently attended to practical medicine, surgery, and midwifery, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union during six months. He must have acquired proficiency in vaccination. He must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied. Candidates are examined in General Pathology, General Therapeutics, and Hygiene; Surgery; Medicine; Midwifery; Forensic Medicine. The examinations include questions in surgical and medical anatomy, pathological anatomy, and pathological chemistry, and practical examinations of patients, preparations, operations, etc. A candidate who has been placed in the first division may be examined for honours in (1) Medicine, (2) Midwifery, and (3) Forensic Medicine. If sufficient merit be evinced, the candidate who distinguishes himself the most in medicine receives 50*l.* per annum for two years, with the style of University Scholar in Medicine; and the candidates who distinguish themselves the most in midwifery and in forensic medicine receive each 30*l.* per annum for two years, with the style of University Scholar in Obstetric Medicine and in Forensic Medicine. The first and second candidates in each of the preceding subjects each receive a gold medal, value 5*l.*

BACHELOR OF SURGERY.—The candidate must: 1. Have taken the degree of Bachelor of Medicine in this University; 2. Have attended a course of instruction in operative surgery, and have operated on the dead subject. The examinations are conducted by printed papers on surgical anatomy and surgical operations; by examination and report on cases of surgical patients; by performance of operations upon the dead subject; by application of surgical apparatus; and by *viva voce* interrogation. Any candidate who has been placed in the first division at the examination may be examined for honours. If sufficient merit be evinced, the candidate who distinguishes himself the most receives 50*l.* per annum for two years, with the Style of University Scholar in Surgery; and the first and second candidates each receive a gold medal, value 5*l.*

MASTER IN SURGERY.—The candidate must: 1. Have taken the degree of Bachelor of Surgery in this University; 2. Have attended subsequently—(a) to clinical or practical surgery during two years in a hospital or medical institution recognised by this University; (b) or to clinical or practical surgery during one year in a recognised hospital or medical institution, and have been engaged during three

years in the practice of his profession; (c) or have been engaged during five years in the practice of his profession. Candidates are examined in logic and moral philosophy, and in surgery. If sufficient merit be evinced, the candidate who distinguishes himself the most at this examination receives a gold medal of the value of 20*l.*

DOCTOR OF MEDICINE.—The candidate must produce certificates analogous to those required for candidates for the degree of Master in Surgery, but having special relation to medicine. The examination is conducted by printed papers and *viva voce* interrogation; and candidates are examined in Logic and Moral Philosophy, and in Medicine. If sufficient merit be evinced, the candidate who distinguishes himself the most receives a gold medal of the value of 20*l.*

UNIVERSITY OF DURHAM.

This University grants the degrees of Bachelor of Medicine, Doctor of Medicine, and Master in Surgery; also Licenses in Medicine and in Surgery.

LICENSE IN MEDICINE.—The candidate must be of the age of twenty-one years, and must, after registration, have spent four years in medical study at one or more of the schools recognised by the Licensing Bodies. One year at least must be spent at the College of Medicine at Newcastle-on-Tyne. There are two public examinations: the first, in Anatomy, Physiology, and Chemistry, after two years at least of medical study; the second, after four years at least of medical study.

BACHELOR OF MEDICINE.—The candidate must be of the standing of three terms at least as a Licentiate of Medicine, and of six years at least from the date of registration. He must have obtained a Degree in Arts of the University of Durham, or have passed the final examination for the Degree of Bachelor of Arts, or an equivalent to it. The candidate must write an essay on some medical subject, selected by himself and approved by the Professor of Medicine, and pass an examination thereon, including the collateral medical branches involved in the subject of the essay.

DOCTOR OF MEDICINE.—The candidate must be of the standing of three terms at least as a Bachelor of Medicine in the University, and of seven years from his registration or matriculation; and must have passed the examination for the degree of Doctor of Medicine, which is similar to that for the degree of Bachelor.

LICENSE IN SURGERY.—The regulations are similar to those for the License in Medicine; but the second examination is directed more particularly to Surgery, and may be passed at the same time with the final examination for a License in Medicine.

MASTER IN SURGERY.—The candidate must be a Licentiate in Surgery and in Medicine, and of the standing of six years at least from registration or matriculation, and of three terms at least from the date of the License in Surgery.—[In other respects, the regulations for this degree are analogous to those for that of Bachelor of Medicine.] The examination for this degree is directed chiefly to the Practice of Surgery.

Candidates for the Degrees of Master in Surgery, Bachelor of Medicine, and Doctor of Medicine must reside and pursue the Arts Course for three terms either in Durham or at Newcastle, in addition to the four years of medical study.

Jan., April, May, July, November. | At end of medical studies, in Medicine, Pathology, Therapeutics, Midwifery and Diseases of Women and Children, Forensic Medicine and Toxicology. Every Wednesday and Thursday. |
| THIRD EXAMINATION; AT WHAT PERIOD IT MAY BE PASSED; SUBJECTS; DATES WHEN HELD. | After completion of required course of study in Medical Anatomy, Medicine, including Public Health and Psychology; Examination of Medical Patients. | | | | |

| | | | | | | | |
|--------------------|--|--|--|---|--|---|--|
| FEES PAYABLE . . . | 3 <i>l.</i> 10 <i>s.</i> | 15 <i>l.</i> 15 <i>s.</i> ; 5 <i>l.</i> 5 <i>s.</i> at first examination, not returned in case of rejection, but candidate admitted to one subsequent first examination without additional fee. After rejection at second examination, fee returned, minus 3 <i>l.</i> 3 <i>s.</i> | After rejection at first examination, not again admitted until end of three months; after second examination, not till end of six months. Evidence of professional study during interval required in both cases. | Candidates who have passed examinations in Anatomy and Physiology of other licensing body; who have obtained Degree in Medicine or in Surgery at a recognised university; who have passed examination in Surgery at a College of Surgeons; or who have obtained Degrees in Medicine; or who are above forty years of age. | Candidates who have degrees of B.A. or M.A. of an University in the United Kingdom are required to study for <i>five</i> years only. Members of College, after eight years, admitted to examination. | Candidates who have studied in Scotland or in Ireland or at recognised Foreign or Colonial Universities, members or licentiates of the other Colleges of Surgeons in United Kingdom, and Graduates in Medicine or Surgery of a recognised University. | Graduates in Medicine of British Universities; Licentiates and members of Colleges of Physicians and Surgeons in United Kingdom or of Apothecaries' Hall in Ireland; candidates who have passed the first professional examination of other boards; candidates apprenticed before August 1, 1858, or who commenced hospital attendance on or before October 1, 1861. |
| REJECTED DATES. | CANDIDATES EXEMPTED FROM CERTAIN PORTIONS OF THE EXAMINATIONS OR ADMITTED UNDER SPECIAL REGULATIONS. | After rejection at first examination, not admitted until end of three months; at second examination, not till end of six months. In both cases certificates of professional study in interval required. After rejection at third examination, not re-admitted (except by special permission) till end of one year. | After rejection at primary examination, candidate must dissect for three months; after second examination, must attend Surgical Hospital Practice and Lectures on Clinical Surgery for six months. | After rejection at first examination, candidate cannot be again admitted till after three months; after examination for licence not till after six months. | After rejection at first examination, candidate cannot be again admitted till after three months; after examination for licence not till after six months. | After rejection at first examination, candidate cannot be again admitted till after three months; after examination for licence not till after six months. | Certificate of qualification to practice, 6 <i>l.</i> 6 <i>s.</i> ; half retained in case of rejection and accounted for at subsequent examination. First examination, 3 <i>l.</i> 3 <i>s.</i> , retained in case of rejection and accounted for subsequently. |

ROYAL COLLEGES OF PHYSICIANS AND OF SURGEONS OF EDINBURGH.

DOUBLE QUALIFICATION IN MEDICINE AND IN SURGERY.

These colleges give their separate diplomas in medicine and surgery, under conditions generally similar to those described below. Particulars may be obtained on application to the colleges. They have also made arrangements by which, after one series of examinations, the student may obtain the diplomas of both colleges, and register two qualifications—Licentiates of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh. Every candidate must have studied in an University, or in an established School of Medicine, or in a recognised Provincial School. Candidates must have been engaged during four years after examination in general education, in not less than four winter sessions', or three winter and two summer sessions', attendance at a recognised medical school. Candidates must have attended the following course of lectures: Anatomy, two courses of six months each, and Practical Anatomy, twelve months; or Anatomy, one course of six months, and Practical Anatomy, twelve months; or Anatomy, one course of six months, and Practical Anatomy, eighteen months; Physiology, not less than fifty lectures; Chemistry, Practice of Medicine, Clinical Medicine; Medicine (a third course, either Practice or Clinical), Principles and Practice of Surgery, Clinical Surgery, Surgery (a third course, either Principles and Practice or Clinical Surgery), each six months; Practical or Analytical Chemistry, Materia Medica, Midwifery, and Diseases of Women and Children, Medical Jurisprudence, and Pathological Anatomy, each three months. He must also (a) have attended at least six cases of labour; (b) have attended, for three months, instruction in Practical Pharmacy; (c) have attended, for twenty-four months, a public General Hospital, containing at least eighty patients; (d) have attended, for six months, the practice of a public Dispensary specially recognised, or have been engaged for six months as assistant to a registered practitioner; (e) have been instructed in vaccination. Students are recommended to attend lectures on Ophthalmic and Mental Diseases, and on Natural History and Comparative Anatomy; and to obtain practical instruction in the use of the Microscope. Candidates for the Diplomas must have passed the examination in General Education, and have had their names inscribed in the General Medical Council's Register of Medical Students. Certificates of having passed the examinations in General Education, conducted by bodies recognised by the General Medical Council, will be accepted as equivalent. Candidates for the double qualification are subjected to two professional examinations. The first examination embraces Anatomy, Physiology, and Chemistry; and takes place not sooner than the end of the second winter session. The sum of 6*l.* must be paid for this examination, and will be considered as paid to account for the entire fee of 16*l.* payable for the two Diplomas. In the case of a candidate being unsuccessful at this examination, 4*l.* will be returned to him. The second examination embraces Medicine, Surgery, and Surgical Anatomy, Midwifery, Pathological Anatomy, Materia Medica and Pharmacy, and Medical Jurisprudence; and takes place after the termination of the

winter session of the last year of study, and not until four years after the examination in general education; the fee for this examination is 10*l.* In case of a candidate being unsuccessful at this examination, 3*l.* will be returned to him. Candidates who have passed the first professional examination in Anatomy, Physiology, and Chemistry, at any of the Licensing Boards recognised by the Medical Act, will be admissible to the second professional examination on producing certificates of the whole course of study prescribed, and of having passed their preliminary and first professional examinations, 16*l.* In addition to written and oral examinations, all candidates are subjected to a practical Clinical Examination in Medicine and Surgery. No candidate is admissible to examination who has been rejected by any other Licensing Board within the three preceding months. Communications from candidates to be addressed to Dr. Gairdner, Inspector and Treasurer of the Double Qualification, at 45, Northumberland Street, Edinburgh. The following will be the periods of examination for the Double Qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh, for the year 1874-5:—*Preliminary Examination in General Education*, October 20 and 21, 1874, April 20 and 21, and July 24 and 25, 1875. *First Professional Examinations*.—Tuesdays, November 3, 1874; February 2, April 13, May 4, July 20, and August 3, 1875. *Second Professional Examinations*. These will take place immediately after the conclusion of the first professional examinations. In no case will they be begun on an earlier day than the Thursday of any period.

Conjoint examinations are also held, and double qualifications granted, under similar regulations, by the Royal College of Physicians in Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.

THE UNIVERSITIES OF SCOTLAND.

The four Scottish Universities—Edinburgh, Glasgow, Aberdeen, and St. Andrews, confer each the degrees of Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The degree of Master in Surgery is not conferred on any one who does not obtain the degree of Bachelor of Medicine.

The regulations for the M.B. degree as to age, preliminary education, and curriculum of study, are in their general character similar to those for the conjoint diplomas of the Royal Colleges of Physicians and Surgeons in Edinburgh; but one of the five years of medical study required must have been spent in the University the degree of which is sought. The Universities of Aberdeen and St. Andrews require an inaugural dissertation to be presented composed by the candidate for the degree of M.B.; but at Edinburgh and Glasgow this is not required until the degree of M.D., is taken.

Degree of Doctor in Medicine.—A candidate for the degree of doctor of medicine must have obtained the degree of bachelor of medicine, be twenty-four years of age, and have been engaged, subsequently to having received the degree of M.B., for two years in attendance on an hospital, or in the military or naval medical service, or in medical or surgical practice. The degree of doctor is not conferred on any person unless he be a graduate in arts, or unless he shall, before or at the time of his obtaining the degree of bachelor of medicine, or

within three years thereafter, have passed a satisfactory examination in Greek, and in logic or moral philosophy, and in one at least of the following subjects, namely, French, German, higher mathematics, natural philosophy, and natural history. As above-mentioned, the Universities of Edinburgh and Glasgow require a thesis to be presented; and the regulations of the Edinburgh University state that 'no thesis will be approved by the medical faculty which does not contain either the results of original observations in practical medicine, surgery, midwifery, or some of the sciences embraced in the curriculum for the bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.' Gold medals are awarded by the University of Edinburgh to the authors of the best thesis, if deemed worthy.

METROPOLITAN MEDICAL SCHOOLS.

The winter session will commence in the London Medical Schools on October 1; when introductory addresses will be given, at Charing Cross Hospital by Dr. Douglas Powell, at 4 P.M.; at St. George's Hospital, by Dr. Dickinson, at 4 P.M.; at Guy's Hospital, by Sir William Gull, Bart., M.D., F.R.S., at 2 P.M.; at King's College, by Dr. Ferrier, at 4 P.M.; at the London Hospital, by Dr. S. Fenwick, at 3 P.M.; at St. Mary's Hospital, by Mr. Owen, at 3.30 P.M.; at the Middlesex Hospital, by Mr. A. Clark, at 3 P.M.; at St. Thomas's Hospital, by Mr. Mac Cormac, at 2 P.M.; at University College, by Dr. Roberts, at 3 P.M.; and at the Westminster Hospital, by Dr. Potter, at 8 P.M. No introductory lecture is given at St. Bartholomew's Hospital.

ST. BARTHOLOMEW'S HOSPITAL. — *Consulting Physicians*.—Sir G. Burrows, Bart., D.C.L., F.R.S. Dr. Farre. *Consulting Surgeon*.—Sir J. Paget, Bart., D.C.L., F.R.S. *Physicians*.—Dr. Black, Monday, Tuesday, and Thursday, 1. Dr. Harris, Tuesday, Thursday, and Saturday, 1.30. Dr. Andrew, daily except Wednesday, 1.30. Dr. Southey, Monday, Wednesday, Thursday, and Saturday, 1.30. *Surgeons*.—Mr. Holden, Tuesday, Friday, and Saturday, 1.30. Mr. Savory, Monday, 1; remaining days of week, 1.30. Mr. Callender and Mr. Thomas Smith, daily, 1.30. *Physician-Accoucheur*.—Dr. Greenhalgh, Thursday, 1.30. *Out-patients*, Saturday, 9. *Ophthalmic Surgeons*.—Mr. Power, Tuesday and Thursday, 1.30. Mr. Vernon, Thursday and Saturday, 1.30. *Assistant Physicians*.—Dr. Church, Tuesday and Friday, 11. Dr. Gee, Wednesday and Saturday, 11. Dr. Duckworth, Monday and Thursday, 11. Dr. Hensley. *Assistant-Surgeons*.—Mr. Willett, Wednesday and Saturday, 12.30. Mr. Langton, Tuesday and Friday, 12.30. Mr. Morrant Baker, Monday and Thursday, 12.30. Mr. Marsh. *Diseases of Skin*.—Dr. Duckworth, Friday, 1.30. *Orthopædic Surgery*.—Mr. Willett, Friday, 12.30. *Diseases of Ear*.—Mr. Langton, Friday, 2.30. *Dental Surgeon*.—Mr. Coleman, Friday, 9. *Casualty Physicians*.—Dr. Hollis, Dr. Wickham Legg, Dr. Brunton, F.R.S. *Lectures: Winter Session*.—Dr. Black and Dr. Andrew, Monday, Tuesday, and Thursday, 3.30. Fee: one course, 5*l.* 5*s.*; unlimited 7*l.* 7*s.* *Surgery*.—Mr. Savory, F.R.S. and Mr. Callender, F.R.S., Wednesday and Thursday,

2.30, Saturday, 9.30 A.M. Fee: one course, 5*l.* 5*s.*, unlimited, 7*l.* 7*s.* *Practical Surgery*.—Demonstrator, Mr. Willett, Monday, Wednesday, and Friday, 2.30. One course 5*l.* 5*s.*, unlimited, 7*l.* 7*s.* *Operative Surgery*.—One course, 4*l.* 4*s.* *Descriptive and Surgical Anatomy*.—Mr. T. Smith and Mr. Langton, Tuesday, Wednesday, Thursday, and Friday, 9 A.M. One course, 7*l.* 7*s.*; unlimited, 10*l.* 10*s.* *Practical Anatomy*.—Under superintendence of lecturers on Anatomy and Physiology. Demonstrators, Mr. Cumberbatch, Mr. Furner, Mr. Walsham. Assistant Demonstrator, Mr. Cripps, 10.15 to 4 daily. Dissecting rooms are open from 7 A.M. to 4 P.M. *General Anatomy and Physiology*.—Mr. Morrant Baker, Monday, Tuesday, and Friday 2.30. One course, 7*l.* 7*s.*; unlimited, 10*l.* 10*s.* *Practical Physiology*.—Mr. Symons, in winter, Monday, Thursday, Friday, 10; Tuesday, 2.30; in summer, Monday, Tuesday, Friday, 11. Fee: one course, 5*l.* 5*s.*; unlimited, 7*l.* 7*s.* *General Histology*.—(Part of Course of Practical Physiology) Dr. Klein, Monday, 2.30. One course, 2*l.* 2*s.* *Chemistry*.—Dr. Russell, F.R.S., Monday, Wednesday, Friday, 10. Fee: one course, 5*l.* 5*s.*, unlimited, 7*l.* 7*s.* *Hygiene*.—Dr. Southey, Friday, 3.30, in January and February. *Dental Surgery and Pathology*.—Mr. Coleman, Friday, 10.30, in October, November, and December: one course, 2*l.* 2*s.*; unlimited, 3*l.* 3*s.* *Materia Medica and Therapeutics*.—Dr. Farre and Dr. Lauder Brunton, F.R.S., Tuesday, Thursday, and Saturday, 10; Wednesday, 11. Fee: one course, 5*l.* 5*s.*; unlimited, 6*l.* 6*s.* *Rotary and Vegetable Physiology*.—Rev. G. Henslow, Monday, Wednesday, and Friday, 10. Fee: one course, 3*l.* 3*s.*; unlimited, 4*l.* 4*s.* *Forensic Medicine*.—Dr. Southey, Tuesday, Thursday, and Saturday, 9. Fee: one course, 3*l.* 3*s.*; unlimited, 4*l.* 4*s.* *Midwifery and Diseases of Women and Children*.—Dr. Greenhalgh, Tuesday, Wednesday, Friday, and Saturday, 8.30 A.M. Fee: one course, 5*l.* 5*s.*; unlimited, 6*l.* 6*s.* *Ophthalmic Medicine and Surgery*.—Mr. H. Power, Tuesday and Wednesday, 12.45. One course, 2*l.* 2*s.*; unlimited, 3*l.* 3*s.* *Ophthalmic Demonstrations*.—Mr. Vernon (in winter), Wednesday, 2. *Comparative Anatomy*.—Dr. Church, Monday and Thursday, 11. One course, 2*l.* 2*s.*; unlimited, 3*l.* 3*s.* *Pathological Anatomy*.—Dr. Gee, Wednesday, 9.30. One course, 2*l.* 2*s.*; unlimited, 3*l.* 3*s.* *Practical Chemistry*.—Dr. Russell, F.R.S. Monday, Wednesday, and Friday, 11. One course, 2*l.* 2*s.* *Psychological Medicine*.—Dr. Clay Shaw, Thursday, 12. One course, 2*l.* 2*s.*; unlimited, 3*l.* 3*s.* *Clinical Lectures by the Physicians*: by Sir James Paget (Consulting Surgeon) and the Surgeons, at times to be arranged in the course of the session. Medical Tutor and Warden of the College, Dr. Norman Moore; Medical Registrar, Dr. Hollis; Surgical Registrars, Mr. Butlin and Mr. Milner. General Fee for attendance on Lectures and Hospital Practice, 105*l.* 5*s.*, payable in the following instalments: First Winter, 36*l.* 15*s.*; First Summer, 36*l.* 15*s.* Second Winter, 36*l.* 15*s.*, or a single payment of 105*l.* Payment in either of these ways entitles the student to a perpetual ticket. Fees for Hospital Practice (Medical): three months, 8*l.* 8*s.*; six months, 12*l.* 12*s.*; two years, 18*l.* 18*s.*; unlimited, 26*l.* 5*s.* Surgical: three months, 10*l.* 10*s.*; six months, 15*l.* 15*s.*; twelve months, 21*l.*; Unlimited, 26*l.* 5*s.* House-Physicianships and House-Surgeoncies: twelve months, 26*l.* 5*s.* (These officers receive each a salary of 25*l.* Dresserships: three

months, 12*l.* 12*s.*; six months, 18*l.* 18*s.*; twelve months, 26*l.* 5*s.*

The hospital contains 710 beds, of which 227 are for medical and 322 for surgical cases. The anatomical museum contains carefully selected specimens of human, and of comparative, and of pathological anatomy, and also numerous models, casts, diagrams, and drawings. The anatomical museum, and the museums of materia medica and of botany are open daily from 10 to 4. The library contains all the standard works of medical, surgical, and the allied sciences, with duplicate copies of books in most general use, the chief medical and other periodicals, and a valuable collection of works on religion, history, and general literature.

The reading room is open for the use of students every day—during the winter from 10 to 5; during the summer from 9 to 5; during the vacations, from 10 to 2.30. The subscription for one year is 1*l.* 1*s.*; for four years, 2*l.* 2*s.*

CHARING CROSS HOSPITAL.—*Consulting Surgeon*, Mr. Hancock. *Physicians*.—Dr. A. J. Pollock; Dr. A. Silver; Dr. T. Henry Green. *Assistant-Physicians*.—Dr. Douglas Powell; Dr. G. V. Poore; Dr. J. Mitchell Bruce; Dr. J. P. Irvine. *Surgeons*.—Mr. E. Canton; Mr. F. Hird; Mr. R. Barwell. *Assistant-Surgeons*.—Mr. E. Bellamy; Mr. Fairlie Clarke; Mr. J. A. Bloxam. *Physician Accoucheur*. Dr. J. Watt Black. *Physician for Skin-Diseases*. Dr. E. Sparks, M.B., M.A. *Dental Surgeon*.—Mr. J. Fairbank. *Chloroformist*.—Mr. F. W. Braine, F.R.C.S. *Medical Registrar*.—Dr. J. M. Bruce. *Surgical Registrar*.—Mr. M. McHardy. *Lectures*: Anatomy, Mr. Bellamy, Monday, Wednesday, Friday, 9; Thursday, 3. Physiology, Dr. Silver, Monday, Tuesday, Wednesday, Friday, 3.30. Medicine, Dr. Pollock, Monday, Wednesday, Friday, 12.30. Surgery, Mr. Canton, Tuesday, Thursday, Saturday, 9. Chemistry, Mr. Heaton, Monday, Thursday, Friday, 11. Dissections, Dr. Cantlie, daily, 10. Materia Medica, Dr. Powell, Tuesday, Thursday, Saturday, 9.45. Midwifery, Dr. Black, Monday, Tuesday, Wednesday, Thursday, 3. Forensic Medicine, Dr. Poore, Monday, Wednesday, Friday, 9. Pathology, Dr. Green, Tuesday, Friday, 3; Wednesday, 4. Botany, Dr. Dowson, Tuesday, Thursday, Saturday, 11. Practical Chemistry, Mr. Heaton, Monday, Friday, 10 to 1. Comparative Anatomy, Mr. Garrod, Tuesday, Friday, 4. Public Health, Mr. Heaton, Dr. Poore, and Mr. Eassie, Tuesday, Thursday, Friday, 2. Psychological Medicine, Dr. Hunt, Monday, 12 (summer). Dental Surgery, Mr. Fairbank, Mon., Wed., Fri., 9.30. Auscultation, Dr. Green, Sat. Case Taking, Dr. Powell. Diseases of Children, Dr. Bruce, Wed. and Sat. Practical Histology, Dr. Bruce, in winter. Laryngoscopic Demonstrations, Dr. Sparks, Thurs. in Oct., Wed. in Dec. Electro-Therapeutics, Dr. Poore, Tues. and Fri. in Feb. Aural Surgery, Mr. Bloxam, Oct. Nov. Dec. Practical Surgery (*in summer*).—(a) Operations, Mr. Bellamy, Thurs.; (b) Bandaging, Mr. F. Clarke, Thurs.; (c) Pathology, Mr. Bloxam, Tues. Skin Diseases, Dr. Sparks, Thurs. Demonstrations of Bones and Ligaments, Dr. Cantlie, daily, except Sat. Morbid Histology, Dr. Bruce. Operative Surgery, Mr. Bellamy, daily in summer. The fees for the classes are mostly different for 'matriculated' and 'non-matriculated' students. The matriculation fee is 2*l.* 2*s.*; and students who have paid this fee are not charged for

attendance on several of the departments of practical study. *Fees for Hospital*.—*Practice* for the full period required by the University of London and the metropolitan licensing bodies, including clinical courses, 31*l.* 10*s.* Non-Matriculated students pay the following fees:—Either medical or surgical practice, three months, 6*l.* 6*s.*; six months, 10*l.* 10*s.*; twelve months, 15*l.* 15*s.*; full period, 21*l.* Both medical and surgical practice, three months, 10*l.* 10*s.*; six months, 15*l.* 15*s.*; twelve months, 21*l.*; full period, 31*l.* 10*s.* For a longer period, 5*l.* 5*s.* for each additional winter, and 3*l.* 3*s.* for each additional summer session.

ST. GEORGE'S HOSPITAL.—*Consulting Physicians*.—Dr. Wilson, Dr. Pitman. *Consulting Surgeons*.—Mr. Caesar Hawkins, F.R.S., Mr. Tatum. *Physicians*.—Dr. Barclay and Dr. Ogle, Monday, Friday, at 1 P.M.; Dr. Wadham and Dr. Dickinson, Tuesday, Saturday, 1 P.M. *Assistant-Physicians*.—Dr. Whipham, Monday, Friday, 12 A.M.; Dr. Cavafy, Tuesday, Saturday, 12 A.M. *Physician Accoucheur*.—Dr. John Clarke, in-patients, Tuesday, Saturday, 1 P.M.; out-patients, Thursday, 12 A.M. *Assistant-Physician Accoucheur*.—Dr. R. J. Lee, in-patients, Tuesday, Saturday, 1 P.M.; out-patients, Thursday, 12 A.M. *Surgeons*.—Mr. Prescott Hewett, F.R.S., and Mr. Pollock, Monday, Friday, 1 P.M.; Mr. Henry Lee Mr. Holmes, Tuesday, Saturday, 1 P.M.; *Assistant-Surgeons*.—Mr. Rouse, Tuesday, Saturday, 12 A.M.; Mr. Pick, Monday, Friday, 12 A.M. *Ophthalmic Surgeon*.—Mr. Brudenell Carter, Wednesday, Saturday, 2 P.M. *Aural Surgeon*.—Mr. Dalby, Tuesday, 2 P.M. *Dentist*.—Mr. Vasey, Tuesday, Saturday, 9 A.M.; Thursday, 1 P.M. *Orthopaedic Outpatients*.—Mr. Pick, Wednesday, 2 P.M. *Diseases of Skin*.—Dr. Whipham, Thursday, 2 P.M.

Lectures.—Descriptive and Surgical Anatomy.—Mr. Rouse, Monday, Wednesday, Friday, 3 P.M. One course, 6*l.* 6*s.*; perpetual, 7*l.* 7*s.* Practical Anatomy, Demonstrator, Mr. Frost; Assistant-Demonstrator, Mr. Dunbar. Demonstrations on Osteology by Mr. Frost. A fee of 3*l.* 3*s.* is charged to each student requiring a certificate, for expenses. Physiology and General Anatomy.—Dr. Cavafy, Tuesday, Thursday, 3 P.M.; Friday 11 A.M. One course, 6*l.* 6*s.*; perpetual, 7*l.* 7*s.* Physiological Chemistry.—Mr. S. W. Moore, Monday, Wednesday, Friday, 10 A.M. Microscopical Anatomy.—Mr. Herbert Watney, Tuesday, Thursday, Saturday, 10 A.M. Comparative Anatomy, Dr. Cavafy, Monday, Friday, 4.30 P.M. Fee, one course, 4*l.* 4*s.* Principles and Practice of Physic. Dr. Barclay, Tuesday, Thursday, Saturday, 9 A.M. Fee, one course, 6*l.* 6*s.*; perpetual, 7*l.* 7*s.* Psychological Medicine.—Dr. Blandford. Pathology.—Mr. Dickinson, Thursday, 3 P.M. Fee, one course, 3*l.* 3*s.* Morbid Anatomy.—Mr. J. W. Haward. Principles and Practice of Surgery.—Mr. Holmes and Mr. Pick, Monday, Wednesday, Friday, 9 P.M. Fee, one course, 6*l.* 6*s.*; perpetual, 7*l.* 7*s.* A course of lectures in winter, and a summer course of practical instruction in minor surgery, operative surgery, bandaging, etc. Operative Surgery.—Mr. Pick, Monday, Wednesday, Friday, 3 P.M. Fee of 2*l.* 2*s.* charged, in order to provide subjects.—Ophthalmic Surgery.—Mr. Brudenell Carter, Monday, 10 A.M. Dental Surgery.—Mr. Vasey, Tuesday, 10 A.M. Aural Surgery.—Mr. Dalby, Wednesday, 3 P.M. Chemistry.—Dr. Noad, F.R.S., Tuesday, Thursday, Saturday, 11.30 A.M. Fee, one course, 6*l.* 6*s.*; perpetual, 8*l.* 8*s.* Practical Chemistry.—Dr. Noad, Monday, Wednesday, Thursday, Friday, 10 A.M.

Fee for the use of apparatus and materials, 4*l.* 4*s.* Midwifery and Diseases of Women and Children.—Dr. John Clarke, and Dr. R. J. Lee, Monday, Wednesday, Friday, 9 A.M. Fee, one course, 5*l.* 5*s.*; perpetual, 6*l.* 6*s.* Materia Medica.—Dr. Dickinson, Monday, Wednesday, Friday, 3 P.M. Fee, one course, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.* Medical Jurisprudence.—Dr. Wadham, Tuesday, Thursday, Saturday, 9 P.M. Fee, one course, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.* Botany.—Dr. Whipham, Tuesday, 3 P.M.; Wednesday, Thursday, 12 A.M. Fee, one course, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.* Clinical Medicine.—Winter, Monday, Friday, 2 P.M.; summer, Monday, 2 P.M. Clinical Surgery.—Tuesday, 2 P.M. Clinical Ophthalmic Surgery.—Wednesday, Saturday, 3 P.M. Operations.—Thursday, 1 P.M.; in eye, Friday, 1.15 P.M. General fee for perpetual pupils (exclusive of Practical Chemistry), 105*l.*, in one payment. For hospital practice and lectures required by examining boards (except Practical Chemistry), 42*l.* for each of the first and second years, and 10*l.* 10*s.* for each succeeding year; gentlemen entering under this rule can become perpetual pupils by making up the payments to 115*l.* 10*s.* Lectures and hospital practice required for diploma in Dental Surgery of Royal College of Surgeons, 4*l.* 5*s.* Hospital Practice.—Medical, six months, 8*l.* 8*s.*; three years, 16*l.* 16*s.*; perpetual, 25*l.* 5*s.*; surgical, six months, 15*l.* 15*s.*; three years, 21*l.*; perpetual, 42*l.*

The hospital contains 350 beds, of which 200 are devoted to the reception of surgical, and 150 to medical cases.

Wards are especially set apart for the reception of cases of diseases of the eye, and diseases peculiar to women. In all the women's wards cribs are placed for the reception of children.

The pupils requiring certificates of attendance on hospital practice will be placed under the superintendence of the physicians and surgeons in rotation, and will have charge of the cases as clinical clerks and dressers. The library and reading-room are open during the greater part of the day. Every pupil subscribes 10*s.* 6*d.* to the library, at the commencement of each winter session; or may pay a compounding fee of 2*l.* on entrance. The museum is open daily to the pupils of the hospital. Gentlemen who have not already received instruction in pharmacy, may do so in the laboratory and dispensary of the hospital upon payment of a fee of 3*l.* 3*s.* Particular attention will be paid to that branch of pharmacy which will fit the students for private dispensing.

GUY'S HOSPITAL.—*Consulting Physicians*.—Sir William Gull, Bart., M.D., D.C.L., F.R.S. Dr. Owen Rees, F.R.S. *Consulting Surgeons*.—Mr. J. Hilton, F.R.S. Mr. Cock. *Consulting Obstetric Physician*.—Dr. Oldham. *Physicians*.—Dr. Habershon, Tuesday, Thursday, and Saturday, 1.30. Dr. Wilks, Monday and Thursday, 1.30. Dr. Pavy, Monday and Friday, 1.30. Dr. Moxon, Monday, Thursday, and Friday, 1.30. *Assistant Physicians*. Dr. Hilton Fagge, Friday, 12. Dr. Pye-Smith, Wednesday, 12. Dr. F. Taylor, Monday, 12. *Surgeons*.—Mr. Birkett, Mr. Cooper Forster, and Mr. Bryant, Monday and Thursday, 1.30. Mr. Durham, Monday, Thursday, and Friday, 1.30. *Assistant Surgeons*.—Mr. Howse, Monday and Thursday, 12. Mr. Davies-Colley, Wednesday and Saturday, 12. *Obstetric Physician*.—Dr. Braxton Hicks, F.R.S., Tuesday and Friday, 1.30. *Assistant Obstetric*

Physician.—Dr. Galabin (out-patients), Thursday and Saturday, 12; ward, Monday and Friday, 1.30. *Ophthalmic Surgeon*.—Mr. Bader, Tuesday and Saturday, 1.30. *Assistant Ophthalmic Surgeon*.—Mr. Higgins, Tuesday and Friday, 12. *Dental Surgeon*.—Mr. Salter, Thursday, 12. *Assistant Dental Surgeon*.—Mr. Moon, Tuesday and Friday, 12. *Aural Surgeon*.—Mr. Laidlaw Purves, Tuesday and Friday, 12. *Diseases of Skin*.—Dr. Fagge and Dr. F. Taylor, Tuesday, 12. *Medical Registrars*.—Dr. F. Taylor and Dr. Goodhart. *Surgical Registrar*.—Mr. F. Durham. *Apothecary*.—Mr. J. Stocker. *Curator of Museum*.—Dr. Fagge. *Lying-in Charity*.—Dr. Braxton Hicks and Dr. Galabin. *Secretary to School*.—Mr. Stocker. *Dean*.—Dr. F. Taylor. *Winter Courses of Lectures*.—Medicine.—Dr. Wilks and Dr. Habershon, Mondays, Wednesdays, and Fridays, 3. Fee, one course, 5*l.* 5*s.* Clinical Medicine.—Dr. Habershon, Dr. Wilks, Dr. Pavy, and Dr. Moxon, Saturday, 1.30. Surgery.—Mr. Birkett and Mr. Cooper Forster, Tuesdays and Thursdays, 3.30; Friday, 10.30. Fee, one course, 5*l.* 5*s.* Clinical Surgery.—Mr. Birkett, Mr. Forster, Mr. Bryant, and Mr. Durham, Wednesday, 1.30. Descriptive and Surgical Anatomy.—Mr. Durham and Mr. Howse, Tuesday, Wednesday, Thursday, and Friday, 9 A.M. Fee, one course, 5*l.* 5*s.* Physiology and General Anatomy.—Dr. Pavy and Dr. Pye-Smith, Monday, Wednesday, and Friday, 4.15. Fee, one course, 5*l.* 5*s.* Clinical Lectures on Midwifery and Diseases of Women.—Dr. Braxton Hicks, Wednesday, 1.30. Chemistry.—Dr. Debus and Dr. Stevenson, Tuesday, Thursday, and Saturday, 11. Fee, one course, 5*l.* 5*s.* Experimental Philosophy. Mr. W. Reinold, Saturday, 1. Fee, one course, 4*l.* 4*s.* *Demonstrations*.—Practical Surgery.—Mr. Davies-Colley. Fee, one course, 5*l.* 5*s.* Practical Anatomy.—Mr. R. C. Lucas, Demonstrator. Mr. Golding Bird and Mr. Jacobson, Assistant-Demonstrators, daily. Morbid Anatomy.—Dr. Fagge and Dr. Goodhart, daily, 2.30, throughout the year. Fee, one course, 5*l.* 5*s.* Practical Physiology.—Dr. Pye-Smith. Monday, Thursday, and Saturday, 1.30. Fee, one course, 4*l.* 4*s.* *Summer Courses*. *Lectures*.—Materia Medica and Therapeutics, Dr. Moxon, Tues., Thurs., and Fri., at 3. Fee: One course, 4*l.* 4*s.* Midwifery and Diseases of Women, Dr. Braxton Hicks, F.R.S., Tues., Wed., Thurs., and Fri., 9 A.M. Fee: one course, 5*l.* 5*s.* Medical Jurisprudence, Dr. Alfred Taylor, F.R.S., Tues., Thurs., and Sat., 10. Fee: one course, 4*l.* 4*s.* Clinical Medicine, Dr. Fagge, Dr. Pye-Smith, and Dr. F. Taylor, Wed., 1.30. Clinical Surgery, Mr. Howse, and Mr. Davies-Colley, Fri., 1.30. Ophthalmic Surgery, Mr. Bader, Thurs., 2. Clinical Lectures on Diseases of Women, Dr. A. L. Galabin, Mon., 3. Pathology, Dr. Fagge, Sat., 9. Hygiene, Dr. F. Taylor, Wed., 12.15. Fee: one course, 4*l.* 4*s.* Comparative Anatomy and Zoology, Dr. Pye-Smith, Mon. and Fri., 1.30. Fee: one course, 4*l.* 4*s.* Mental Diseases, Dr. Savage, Mon., 10. Botany, Dr. Stokoe, Tues., Thurs., and Sat., 11.30. Fee: one course, 4*l.* 4*s.* Dental Surgery, Mr. Moon. *Demonstrations*.—Practical Chemistry, Dr. Debus, F.R.S., Mon., Wed., and Fri., 10 to 1. Fee: one course, 4*l.* 4*s.* Operative Surgery, Mr. Davies-Colley, Mon. and Thurs., 3.30. Fee: one course, 5*l.* 5*s.* Practical Courses and University Classes in Anatomy, Physiology, Botany, Comparative Anatomy, Morbid Histology, and Natural Philosophy. *Fees for Hospital Practice and Lectures*.—

First year, 40*l.*; Second Year, 40*l.*; Third Year, 20*l.*; and 10*l.* for each succeeding year of attendance. One payment of 100 guineas entitles a student to a perpetual ticket. Pupils attending practical classes are charged for the materials used. Single Courses of Lectures may be attended on the terms mentioned above in connection with each Class. Attendance on either the Medical or the Surgical Practice of the Hospital:—Three months, 10*l.* 10*s.*; Six months, 15*l.* 15*s.*; Perpetual, 26*l.* 5*s.* The Hospital contains accommodation for 690 patients. There are ophthalmic wards with 50 beds, and obstetric wards with 26 beds.—The Museum of Human Anatomy contains the collection of anatomical models made by Mr. Towne, besides about 2,000 preparations.—The Museum of Comparative Anatomy contains 2,000 specimens.—The Museum of Pathological Anatomy contains upwards of 5,000 specimens, with more than 2,000 drawings.—The Museum of Materia Medica contains specimens of the drugs in general use.—The accommodation for class teaching has lately been much enlarged.—The Library contains upwards of 5,000 volumes, and is open to the students daily from 10 A.M. to 4 P.M.

KING'S COLLEGE.—*Winter Session.*—Anatomy.—Professor Curnow, M.D., daily except Mon., 9; fee, one course, 7*l.* 7*s.*; perpetual, 10*l.* 10*s.* Physiology.—Professor Rutherford, M.D., Mon., Wed., Thurs., Fri., 4; one course, 7*l.* 7*s.*; perpetual, 10*l.* 10*s.* Practical Physiology.—Professor Rutherford and demonstrators, Tues., 11.15; one course, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.* Chemistry.—Professor Bloxam, Mon., Wed., Thurs., 10.15; one course, 7*l.* 7*s.*; perpetual, 10*l.* 10*s.* Medicine.—Professor G. Johnson, M.D., F.R.S., Tues., 4; Thurs., Fri., 5; one course or perpetual, 7*l.* 7*s.* Surgery.—Professor Wood, F.R.S., Mon., Tues., Wed., 5; one course or perpetual, 7*l.* 7*s.* *Summer Session.*—Obstetric Medicine.—Professor Playfair, M.D., Tues., Wed., Thurs., Fri., 9 A.M.; one course, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.* Comparative Anatomy.—Professor A. H. Garrod, Tues., Fri., Sat., 10.15; one course, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.* Botany.—Professor Bentley, Mon., Tues., Thurs., Fri., 12.15; one course, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.* Practical Chemistry.—Professor Bloxam and demonstrators, Mon., Thurs., Fri., 10.15; one course, 4*l.* 4*s.*; perpetual, 7*l.* 7*s.* Forensic Medicine.—Professor Ferrier, M.D., Mon., Tues., Wed., Fri., 12.15; one course, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.* Materia Medica.—Professor E. B. Baxter, M.D., Tues., Wed., Thurs., Fri., 8 A.M.; one course, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.* Pathological Anatomy.—Professor Beale, M.B., F.R.S., Tues., Fri., 4; one course, 2*l.* 2*s.*; perpetual, 3*l.* 3*s.* Practical Physiology.—Professor Rutherford and demonstrator, Mon., Wed., Fri., 4; one course, 2*l.* 2*s.*; perpetual, 3*l.* 3*s.* Hygiene.—Professor Guy, M.B., F.R.S. Dental Surgery.—Professor S. Cartwright. Ophthalmology.—Professor Soelberg Wells. Psychological Medicine.—Professor E. Sheppard, M.D.

KING'S COLLEGE HOSPITAL.—*Consulting Physicians.*—Sir Thos. Watson, Bart. M.D., F.R.S.; Dr. G. Budd, F.R.S.; Dr. A. Farre, M.D., F.R.S.; Dr. W. A. Guy, F.R.S.; Dr. W. O. Priestley; Dr. A. B. Garrod, F.R.S. *Physicians.*—Dr. G. Johnson, F.R.S., Mon., Thurs., 2. Dr. Beale, F.R.S., Tues., Sat., 2. Dr. A. B. Duffin, M.D., Wed., Fri., 2. *Physician Accoucheur.*—Dr. Playfair, Tues., Thurs., Sat., 1.30. *Assistant-Physicians.*—Dr. B. Yeo, Tues., Fri., 1. Dr. Rutherford, Mon.,

Thurs., 1. Dr. Ferrier, Wed., Sat., 1. *Assistant Physician Accoucheur.*—Dr. Hayes, Tues., Thurs., Sat., 12.30. *Consulting Surgeon.*—Mr. J. M. Arnott, F.R.S. *Surgeons.*—Sir W. Fergusson, Bart., F.R.S., Tues., Thurs., Sat., 1.30. Mr. J. Wood, F.R.S., Mon., Wed., Fri., 1.30. Mr. H. Smith, Mon., Wed., Fri., 1. *Assistant-Surgeon.*—Mr. Bell, Tues., Thurs., Sat., 1. *Dental Surgeon.*—Mr. Cartwright, Tues., Fri., 10. *Assistant-Dental Surgeon.*—Mr. S. H. Cartwright, Tues., Fri., 10. *Ophthalmic Surgeon.*—Mr. Soelberg Wells, Tues., Thurs., Sat., 1. *Vaccinator.*—Mr. R. W. Dunn, M.R.C.S. *Pathological Registrar.*—Dr. U. Pritchard. *Administrator of Chloroform.*—Mr. Moss. *Fees.*—Matriculated Students, three years, 31*l.* 10*s.*; perpetual, 42*l.*; not Matriculated, three years, 42*l.*; perpetual, 52*l.* 10*s.* *Medical Practice:*—Three months, 6*l.* 6*s.*; six months, 10*l.* 10*s.*; eighteen months, 15*l.* 15*s.*; perpetual, 26*l.* 5*s.* *Surgical Practice:*—Three months, 10*l.* 10*s.*; six months, 15*l.* 15*s.*; twelve or twenty-one months, 21*l.*; perpetual, 31*l.* 10*s.*

LONDON HOSPITAL AND MEDICAL COLLEGE.—*Physicians.*—Dr. Andrew Clark, Monday and Thursday, 2 P.M.; Dr. J. S. Ramskill, Wednesday and Friday 2 P.M.; Dr. Langdon Down, Tuesday and Friday, 2 P.M.; Dr. Hughlings Jackson, Monday and Thursday, 2 P.M.; Dr. H. G. Sutton (out patients), Monday and Thursday, 1.30 P.M. *Surgeons.*—Mr. Hutchinson, Monday and Thursday, 2 P.M. Mr. Maunder, Tuesday and Friday, 1.30 P.M.; Mr. Couper, Wednesday and Saturday, 1.30 P.M.; Mr. Rivington, Monday and Thursday, 1.30 P.M. *Assistant-Physicians.*—Dr. Fenwick and Dr. Woodman, Tuesday and Friday, 1.30 P.M.; Dr. Stephen Mackenzie, Wednesday and Saturday, 1.30 P.M.; Dr. A. E. Sansom, Monday and Thursday, 1.30 P.M. *Assistant-Surgeons.*—Mr. James Adams on Tuesday and Friday, 1.30 P.M.; Mr. Waren Tay and Mr. McCarthy, Monday and Thursday, 1.30 P.M.; Mr. Reeves, Tuesday and Saturday, 1.30 P.M. *Obstetric Physicians.*—Dr. Head in Obstetric Wards, Tuesday and Friday, 1.30 P.M.; Dr. Palfrey in Obstetric Out-patients Department, Wednesday and Saturday, 1.30 P.M. *Ophthalmic Department.*—Mr. James Adams and Mr. Tay, out-patients, Wednesday and Saturday, 9 A.M. *Aural Department.*—Mr. Rivington and Mr. Reeves, Saturday, 9.30 A.M. *Skin Department.*—Mr. McCarthy, Wednesday, 9 A.M. *Dental Department.*—Mr. Barrett, Tuesday, 10 A.M. Operation day, Wednesday, 2 P.M. *Winter Session, 1874-75.*—Medicine.—Dr. Herbert Davies, Dr. J. S. Ramskill, and Dr. Langdon Down, before Christmas, Monday, Wednesday, and Thursday, 9.15 A.M.; after Christmas Thursday, 9.15 A.M., Tuesday and Friday, 4 P.M. Fee: One session, 5*l.* 5*s.*; unlimited, 6*l.* 6*s.* Surgery.—Mr. John Couper, Tuesday, Friday, and Saturday, 9 A.M. In connection with the lectures on Surgery short special courses of lectures on Ophthalmic Diseases will be given in the summer. Fee: One session, 5*l.* 5*s.*; unlimited, 6*l.* 6*s.* Descriptive and Surgical Anatomy.—Mr. Walter Rivington, Monday, Tuesday, Thursday, and Friday, 3 P.M. Fee: One session, 5*l.* 5*s.*; unlimited, 8*l.* 8*s.* Morbid Anatomy and Pathology.—Dr. H. G. Sutton, Thursday, 12.30 P.M. One year, 3*l.* 3*s.*; unlimited, 6*l.* 6*s.* Physiology and General Anatomy, Practical Histology, and the use of the Microscope.—Mr. Jeremiah McCarthy, Monday, Wednesday, and Thursday, 4 P.M. One course, 4*l.* 4*s.*; unlimited, 6*l.* 6*s.* Practical Anatomy.—Mr.

James Adams and Mr. H. A. Reeves, assisted by Prosectors, daily from 10 to 3, excepting Wednesday and Saturday afternoons. One course, 5*l.* 5*s.*; unlimited, 8*l.* 8*s.*; Chemistry.—Dr. Letheby and Dr. Meymott Tidy, Monday, Wednesday, and Friday, 10.30 A.M. One course, or unlimited, 7*l.* 7*s.* Anatomy and Pathology of the Teeth, and Dental Surgery.—Mr. H. J. Barrett. In March, at 5 P.M., on days to be announced. Fee, 2*l.* 2*s.* *Summer Session.*—Midwifery and Diseases of Women and Children.—Dr. Head, Monday, Wednesday, Thursday, and Friday, at 3 P.M. One session, 4*l.* 4*s.*; unlimited, 6*l.* 6*s.* Forensic Medicine.—1. Toxicology. Mr. Rodgers. Daily, except Saturday, during May and first part of June, 10 A.M. 2. Medical Jurisprudence and Public Health.—Dr. C. Meymott Tidy. Daily, except Saturday, during the last part of June and July, 10 A.M. One session, 3*l.* 3*s.*; unlimited, 4*l.* 4*s.* Materia Medica and General Therapeutics. Dr. Prosser James. Tuesday, Thursday, and Friday, 4 P.M. One session, 3*l.* 3*s.*; unlimited, 4*l.* 4*s.* Ophthalmic Diseases.—Mr. Couper. Tuesday and Friday, 8 A.M. in June. One session, 2*l.* 2*s.*; unlimited, 4*l.* 4*s.* Practical Chemistry.—Dr. Letheby. In May, June, and July, on Monday, Thursday, and Saturday, 9 A.M. Fee to students of hospital, 2*l.* 2*s.*; to others, 3*l.* 3*s.* Botany.—Mr. Baker. Monday, Wednesday, and Friday, 11 A.M. One session, 3*l.* 3*s.*; unlimited, 4*l.* 4*s.* Comparative Anatomy.—Tuesday and Thursday, 11 A.M. One session, 3*l.* 3*s.*; unlimited, 4*l.* 4*s.* Operative Surgery.—Mr. C. F. Maunders. Diseases of the Throat.—Dr. Morell Mackenzie. One session, 2*l.* 2*s.*; unlimited, 3*l.* 3*s.* Morbid Anatomy and Pathology.—Dr. G. Sutton. Thursday, 12.30. One year, 3*l.* 3*s.*; unlimited, 6*l.* 6*s.* Clinical lectures.—October, November, Dr. A. Clark, Monday, 2 P.M.; November, December, Dr. Langdon Down, Tuesday, 2 P.M.; January, February, Dr. Ramskill, Wednesday, 3.30 P.M.; February, March, Dr. Hughlings Jackson, Monday, 2 P.M.; May, Dr. Sutton, Tuesday, 2 P.M.; June, Dr. S. Fenwick, Monday, 2 P.M.; July, Dr. Woodman, Saturday, 3 P.M. A Surgical Clinical Lecture weekly. Clinical Obstetric Lecture, Dr. Head, second Friday of each month, 2.30 P.M.; in summer, Dr. Palfrey, alternate Tuesday, 2.30 P.M.

General fee for perpetual attendance on all the lectures, with two years' practical anatomy, and attendance on medical and surgical practice, 94*l.* 10*s.* Composition fee for gentlemen entering at or before the beginning of their second winter session, 73*l.* 10*s.* Perpetual fee for lectures and hospital practice, and two years' practical anatomy, 105*l.* Perpetual fee for lectures alone, 52*l.* 10*s.* Perpetual fee for hospital practice alone, 52*l.* 10*s.* Practical Chemistry (for apparatus, etc.), 2*l.* 2*s.* Library (compulsory), 1*l.* 1*s.* Instruction in Practical Pharmacy, 4*l.* 4*s.* A fee of half a guinea will be charged to those students who do not bring their own microscopes for use in the course of practical physiology. The general fee and the perpetual fee are payable in two instalments of 45 and 50 guineas each respectively at the commencement of each of the first two years of attendance. The perpetual fee can be paid in three instalments, 45 guineas at the commencement of each of the first two years of attendance, and ten guineas at the commencement of the third year. The composition fee is payable in two instalments of 35 guineas. Students who have paid the general fee can become perpetual pupils at any time subsequently by the payment of the additional 10 guineas. Special entries
